Abstract: This paper highlights the possibility of creating quantum neural networks that are trained by Grover's Search Algorithm. The purpose of this work is to propose the concept of combining the training process of a neural network, which is performed on the principles of Grover's algorithm, with the functional structure of that neural network, interpreted as a quantum circuit.

As a simple example of a neural network, to showcase the concept, a perceptron with one trainable parameter - the weight of a synapse connected to a hidden neuron.

Keywords: quantum neural network, machine learning, Grover's algorithm, quantum algorithms, quantum computing, neural network.

Introduction

To illustrate the concept of using Grover's quantum search algorithm for training quantum neural networks, we will use a simple example of a perceptron with one trainable parameter - the weight w_1 . The goal of the neural network will be to convert the value of the input neuron by multiplying it by the weight w_1 . The goal of training our neural network will be to determine the correct ratio between the input parameter and the output (based on a specified training dataset), this ratio will be set as the weight w_1 of the synapse connecting the input neuron I_1 with the hidden H_1 . In the real world, this task could be implemented, for example, in the form of a dynamic calculator for converting currencies or other values. The given example

(Fig. 1) represents a concept that can be scaled up for a task (and a neural network) of any complexity, by adding more inputs and trainable parameters and thus, requiring more quantum bits.

Fig. 1. The proposed example of a neural network.

$$H_1 \text{ input} = I_1 w_1 \quad (1)$$

$$H_1 \text{ output} = f(H_1 \text{ input}) = H_1 \text{ input} \quad (2)$$

The neural network training process will be performed by Grover's algorithm, which will output the weight value w_1 .

Fig. 2. The quantum neural network training circuit

The proposed quantum perceptron training circuit (Fig. 2) is based on a Grover's algorithm [1-3], in which the structure of the oracle function (function that

serves as a search criteria of the Grover's algorithm) is built based on the activation functions of hidden neurons (ex. F_{act} – Fig. 5) and the structure of the neural network itself. The main objective in constructing this training function, is to provide a condition, which could be used in this oracle function to select suitable weight values (ex. comparison operators on Fig. 2 or *Train* - Fig. 5). The input data of the training circuit will consist of prepared training datasets: values of the input neurons $I_1..I_n$, and required output values (in our example: *ReqVal* – Fig. 2). The output data of the algorithm will consist of all possible weight values $w_1..w_n$ that satisfy the training oracle function [4].

The neuron activation function, which in our case is linear and does not contain a certain condition (2), is written inside the oracle of the Grover's algorithm. Additionally, to obtain the training result using Grover's algorithm, a comparison with the required output value was added to the oracle as a condition for choosing suitable values for the weight w_1 (Fig. 2).

Instead of carrying out measurement of the results of the training process, we will input the obtained weights in the example neural network (Fig. 1) written in the form of a quantum circuit, and verify the results (Fig. 3). Gates: *i_1*, *w_1*, *ReqVal*, *O_1* - are comments that are presented for clarity and do not affect calculations. The input values are coded by sets of Pauli-X operations.

Fig. 3.a. Quantum neural network – running the training algorithm and verifying the results¹

¹ Due to binary calculation and comparison operators, it is possible to sometimes receive values that match only within the comparable qubits as a result of the training algorithm. This happens when the multiplication result can not fit in the provided number of qubits, so it is possible to filter out that issue.

Fig. 3.b. Quantum neural network – verifying the weight, received as a result of training

In order to verify training results, it is possible to compare values of output neurons $O_1..O_n$ to the required output values provided by the training datasets $ReqVal_1..ReqVal_n$, by running the neural network with the same input neuron values $I_1..I_n$. For our example (fig. 3), the demonstrated quantum perceptron, built on these concepts, and trained using Grover's algorithm, outputs the value O_1 equal to the required $ReqVal$ for the same input neuron value i_1 . The training values were as follows: $i_1 = 3$, $ReqVal = 6$, the resulting weight $w_1 = 2$, the resulting value of the output neuron is: $O_1 = 6 = ReqVal$.

Therefore, having received the correct weight w_1 , it is possible to convert any other values of the input neuron according to the obtained ratio, as in a conventional neural network, after training. For this, the value of i_1 , will be changed after passing the training stage of Grover's algorithm, using the reversibility principle. The new input value is $i_1 = 5$ or 101_2 , and the resulting value is $O_1 = 10$ or 1010_2 (Fig. 4).

Fig. 4.a. Quantum neural network – changing the input neuron value after training the neural network.

Fig. 4.b. Quantum neural network – result received by changing the input neuron value after training the neural network.

Based on these results, it is possible to propose the following generalizing concept for constructing and training quantum neural networks with Grover's algorithm (Fig. 5).

Fig. 5. The proposed concept of constructing quantum neural networks based on Grover's algorithm.

Conclusion

As a result of this research, a method for creating quantum neural networks, trained by utilizing the principles of Grover's algorithm was proposed. The proposed approach can be up scaled to solve larger and more specific problems, requiring access to a larger number of quantum bits. The use of Grover's algorithm in machine learning is a promising direction in the development of quantum computing, since this approach can reduce the number of epochs (iterations of the training process) required to train a neural network.
