Abstract—We present an analysis of the optimal uplink (UL) SNR of a SIMO Reconfigurable Intelligent Surface (RIS)-aided wireless link. We assume that the channel between base station (BS) and RIS is a rank-1 LOS channel while the user (UE)-RIS and UE-BS channels are correlated Ricean. For the optimal RIS matrix, we derive an exact closed form expression for the mean SNR and an approximation for the SNR variance leading to an accurate gamma approximation to the distribution of the UL SNR. Furthermore, we analytically characterise the effects of correlation and the Ricean K-factor on SNR, showing that increasing the K-factor and correlation in the UE-BS channel can have negative effects on the mean SNR, while increasing the K-factor and correlation in the UE-RIS channel improves system performance. We also present favourable and unfavourable channel scenarios which provide insight into the sort of environments that improve or degrade the mean SNR. We also show that the relative gain in the mean SNR when transitioning from an unfavourable to a favourable environment saturates to $(4 - \pi)/\pi$ as $N \to \infty$.

I. INTRODUCTION

Reconfigurable Intelligent Surface (RIS) aided wireless networks are currently the subject of considerable research attention due to their ability to manipulate the channel between users (UEs) and base station (BS) via the RIS. Assuming that channel state information (CSI) is known at the RIS, one can intelligently alter the RIS phases, essentially changing the channel to improve system performance. Here, we focus on a single user system and assume a common system scenario where a RIS is carefully located near the BS such that a rank-1 line-of-sight (LOS) channel is formed between the BS and RIS. System scenarios with a LOS channel between the BS-RIS and a single-user are also considered in [1]–[4] with motivation for the LOS assumption given in [5]. All of these existing works aim to enhance the system to achieve some optimal system performance (sum rate, SINR, etc.) by tuning the RIS phases. In particular, [3] gives a closed form RIS phase solution without the presence of a direct UE-BS channel for a single user setting, while [4] gives a closed form phase solution with the presence of a direct channel. We note, however, once the optimal RIS has been defined there is no exact analysis of the mean SNR and no analysis of correlation impact on the mean SNR in [1]–[4].

For the UE to RIS and the direct UE to BS links, the presence of scattering is a more reasonable assumption as is spatial correlation in the channels, especially at the RIS where small inter-element spacing may be envisaged. Several papers do consider spatial correlation in the small-scale fading channels [3], [5]–[11], however, these papers are simulation based and no analysis is given on the impact of correlation on the mean SNR.

Statistical properties of the RIS-aided channel have been investigated in existing literature. For example, [12], [13] provide a closed form expression for the mean SNR in the absence of a UE-BS channel with [13] additionally providing a probability density function (PDF) and a cumulative distribution function (CDF) for the distribution of the mean SNR. In [12], [14], an upper bound is given for the ergodic capacity and in [15] a lower bound is given for the ergodic capacity. However, there are no closed form expressions for the mean SNR and SNR variance for an optimum RIS-aided wireless system, in the presence of correlated Ricean UE-BS, UE-RIS fading channels. We further note that the work presented in this paper is an extension for the work done in [16] which considered correlated Rayleigh UE-BS, UE-RIS fading channels.

In this paper, we focus on an analysis of the optimal uplink (UL) SNR for a single user RIS aided link with a rank-1 LOS RIS-BS channel and correlated Ricean fading for the UE-BS and UE-RIS channels. The contributions of this paper are as follows:

- An exact closed-form result for mean SNR and an approximate closed form expression for SNR variance are derived. These are used to show that a gamma distribution provides a good approximation of the UL optimal SNR distribution. Furthermore, using the analysis presented, we are able to reduce the mean SNR and SNR variance expressions when the UE-BS and UE-RIS links are correlated Rayleigh to agree with those in [16].

- The analysis is leveraged to gain insight into the impact of the K-factor and spatial correlation on the mean SNR. We show that increasing the K-factor and correlation in the UE-BS channel has negative effects, while increasing the K-factor and correlation in the UE-RIS channel improves the mean SNR.

- Given the analyses, we present favourable and unfavourable channel scenarios, which provide insight into the sort of environments that would improve and degrade the mean SNR. For systems with a large number of RIS elements, we show that when changing from favourable to unfavourable channel scenarios, improvements in the
mean SNR saturate at a relative gain of \((4 - \pi)/\pi\) as 
\(N \to \infty\).

**Notation:** \(\mathbb{E}\{\cdot\}\) represents statistical expectation. \(\Re\{\cdot\}\) is the Real operator. \(\|\cdot\|_2\) denotes the \(\ell_2\) norm. Upper and lower boldface letters represent matrices and vectors, respectively. \(\mathcal{CN}(\mu, Q)\) denotes a complex Gaussian distribution with mean \(\mu\) and covariance matrix \(Q\). \(\mathcal{U}(a, b)\) denotes a uniform random variable taking on values between \(a\) and \(b\). \(\chi^2_k\) denotes a chi-squared distribution with \(k\) degrees of freedom. \(\mathbf{1}_n\) represents an \(n \times n\) matrix with unit entries. The transpose, Hermitian transpose and complex conjugate operators are denoted as \((\cdot)^T\), \((\cdot)^H\), and \((\cdot)^*\), respectively. The trace and diagonal operators are denoted by \(\text{tr}\{\cdot\}\) and \(\operatorname{diag}\{\cdot\}\), respectively. The angle of a vector \(x\) of length \(N\) is defined as \(\angle x = [\angle x_1, \ldots, \angle x_N]^T\) and the exponent of a vector is defined as \(e^x = [e^{x_1}, \ldots, e^{x_N}]^T\). \(\otimes\) denotes the Kronecker product. \(L_{\nu}\{\cdot\}\) denotes a Laguerre function of non-integer degree \(\nu\).

II. SYSTEM MODEL

As shown in Fig. 1, we examine a RIS aided single user single input multiple output (SIMO) system where a RIS with \(N\) reflective elements is located close to a BS with \(M\) antennas such that a rank-1 LOS condition is achieved between the RIS and BS.

![Fig. 1: System model (the red dashed line is the control link for the RIS phases).](image)

A. Channel Model

Let \(\mathbf{h}_d \in \mathbb{C}^{M \times 1}\), \(\mathbf{h}_{ru} \in \mathbb{C}^{N \times 1}\), \(\mathbf{H}_{br} \in \mathbb{C}^{M \times N}\) be the UE-BS, UE-RIS and RIS-BS channels, respectively. The diagonal matrix \(\Phi \in \mathbb{C}^{N \times N}\), where \(\Phi_{rr} = e^{j\theta_r}\) for \(r = 1, 2, \ldots, N\), contains the reflection coefficients for each RIS element. The global UL channel is thus represented by

\[
\mathbf{h} = \mathbf{h}_d + \mathbf{H}_{br} \Phi \mathbf{h}_{ru},
\]

where we consider the correlated Ricean channels:

\[
\mathbf{h}_d = \sqrt{\beta_d} \left( \eta_d \mathbf{a}_d + \zeta_d \mathbf{R}_d^{1/2} \mathbf{u}_d \right) \triangleq \sqrt{\beta_d} \mathbf{h}_d
\]

\[
\mathbf{h}_{ru} = \sqrt{\beta_{ru}} \left( \eta_{ru} \mathbf{a}_{ru} + \zeta_{ru} \mathbf{R}_{ru}^{1/2} \mathbf{u}_{ru} \right) \triangleq \sqrt{\beta_{ru}} \mathbf{h}_{ru}
\]

with

\[
\eta_d = \sqrt{\frac{\kappa_d}{1 + \kappa_d}}\quad \zeta_d = \sqrt{\frac{1}{1 + \kappa_d}}
\]

\[
\eta_{ru} = \sqrt{\frac{\kappa_{ru}}{1 + \kappa_{ru}}}\quad \zeta_{ru} = \sqrt{\frac{1}{1 + \kappa_{ru}}}
\]

where \(\beta_d\) and \(\beta_{ru}\) are the link gains between UE-BS and UE-RIS respectively, \(\mathbf{R}_d\) and \(\mathbf{R}_{ru}\) are the correlation matrices for UE-BS and UE-RIS links, respectively, and \(\mathbf{u}_d, \mathbf{u}_{ru} \sim \mathcal{CN}(0, \mathbf{I})\). Here, \(\kappa_d\) and \(\kappa_{ru}\) are the Ricean K-factors for the UE-BS and UE-RIS channels, respectively. The LOS paths \(\mathbf{a}_d\) and \(\mathbf{a}_{ru}\) are topology specific steering vectors at the BS and RIS respectively. Particular examples of steering vectors for a vertical uniform rectangular array (VURA) are given in Sec. V.

Note, that the correlation matrices \(\mathbf{R}_{ru}\) and \(\mathbf{R}_d\) can represent any correlation model. For simulation purposes, we will use the well-known exponential decay model,

\[
(\mathbf{R}_{ru})_{ik} = \rho_{ru}^{d_{i,k}}, \quad (\mathbf{R}_d)_{ik} = \rho_d^{d_{i,k}},
\]

where \(0 \leq \rho_{ru} \leq 1, 0 \leq \rho_d \leq 1\). \(d_{i,k}\) is the distance between the \(i\)th and \(k\)th antenna/element at the BS/RIS. \(d_{br}\) and \(d_r\) are the nearest-neighbour BS antenna separation and RIS element separation, respectively, which are measured in wavelength units. \(\rho_{br}\) and \(\rho_{ru}\) are the nearest neighbour BS antenna and RIS element correlations, respectively.

The rank-1 channel from RIS to BS has link gain \(\beta_{br}\) and is given by \(\mathbf{H}_{br} = \sqrt{\beta_{br}} \mathbf{a}_b \mathbf{a}_r^H\) where \(\mathbf{a}_b\) and \(\mathbf{a}_r\) are topology specific steering vectors at the BS and RIS, respectively.

B. Optimal SNR

Using (1), the received signal at the BS is, \(\mathbf{r} = (\mathbf{h}_d + \mathbf{H}_{br} \Phi \mathbf{h}_{ru}) \mathbf{s} + \mathbf{n} \overset{\Delta}{=} \mathbf{h}_d \mathbf{s} + \mathbf{n}\), where \(s\) is the transmitted signal with power \(E_s\) and \(\mathbf{n} \sim \mathcal{CN}(0, \sigma^2 \mathbf{I})\). For a single user, Matched Filtering (MF) is the optimal combining method so the optimal UL SNR is, \(\text{SNR} = \mathbf{h}_d^H \mathbf{h}_d\), where \(\mathbf{h}_d = \sqrt{\beta_{br}} \mathbf{a}_r \psi\). The optimal RIS phase matrix to maximize the SNR can be computed using the main steps outlined in [4] Sec. III-B] but using an UL channel model instead of downlink. Substituting the channel vectors and through some matrix algebraic manipulation, the optimal RIS phase matrix is,

\[
\Phi = \frac{\mathbf{a}_r^H \mathbf{h}_d}{\|\mathbf{a}_r^H \mathbf{h}_d\|} \text{diag}\{e^{j\angle \mathbf{h}_d}\} \text{diag}\{e^{-j\angle \mathbf{h}_{ru}}\}.
\]

Substituting (3) into (1), the optimal UL global channel is,

\[
\mathbf{h} = \mathbf{h}_d + \sqrt{\beta_{br} \beta_{ru}} \mathbf{u} \sum_{n=1}^N \left| \mathbf{h}_{ru,n} \right| \mathbf{a}_b,
\]

where \(\psi = \frac{\mathbf{a}_r^H \mathbf{h}_d}{\|\mathbf{a}_r^H \mathbf{h}_d\|}\) giving the optimal UL SNR as

\[
\text{SNR} = (\mathbf{h}_d^H + \alpha \mathbf{a}_b^H) (\mathbf{h}_d + \alpha \mathbf{a}_b) \mathbf{h}_d^T
\]

where \(\alpha = \sqrt{\beta_{br} \beta_{ru}} \psi Y\) and \(Y = \sum_{n=1}^N \left| \mathbf{h}_{ru,n} \right|\). The \(Y\) variable is given its own notation as it arises in many of the derivations for the SNR.
III. MEAN SNR AND SNR VARIANCE

A. Correlated Ricean Channels

Here, we provide an exact closed form result for \( \mathbb{E}\{\text{SNR}\} \) and an exact expression for \( \text{Var}\{\text{SNR}\} \) when \( h_d \) and \( h_{ru} \) are correlated Ricean channels. Utilising these expressions, we then show that they can be reduced to the expressions given in [16] when \( h_d \) and \( h_{ru} \) are correlated Rayleigh channels.

**Theorem 1.** The mean SNR is given by
\[
\mathbb{E}\{\text{SNR}\} = \left( \frac{N A \Phi_d \sqrt{\beta h_\text{br} h_{\text{ru}} L_1}{}}{2} \right) L_1 \left( -\kappa_d \left| a_d H a_d \right|^2 \right)
\]
\[+ \beta_d M + \beta h_\text{br} h_{\text{ru}} M (N + F_{R}) \right),
\]
with \( F_{R} \) given by
\[
F_R = \sum_{i=1}^{N} \sum_{k=1}^{N} \left( \frac{1 - |\rho_{ik}|^2}{1 + \kappa_{ru}} \right)^2 \exp \left\{ -\frac{2 \kappa_{ru} - 2 |\rho_{ik}|^2}{1 - |\rho_{ik}|^2} \right\}
\]
\[\times \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{\epsilon_m \cos(n \phi)}{m! (m - n)! (n!)^2} \left( \kappa_{ru} \left( 1 + |\rho_{ik}|^2 - 2 |\rho_{ik}| \right) \right)^n
\]
\[\times \Gamma^2 \left( m + \frac{3}{2} \right) \frac{3 F_1}{m + \frac{3}{2}, n + 1, \kappa_{ru} \left( 1 + |\rho_{ik}|^2 - 2 |\rho_{ik}| \right) \right)^n
\]
\[\text{and } A = \left( R_d a_b \right)^2, \text{ where } \rho_{ik} = (R_{ru})_{ik}, 1 F_1(\cdot) \text{ is the confluent hypergeometric function, } \phi = \arg \left\{ (1 + |\rho_{ik}|^2) \mu_c \kappa_{ru} - 2 \kappa_{ru} |\rho_{ik}|^2 + \mu_c (1 - |\rho_{ik}|^2 \mu_c) \right\}, \mu_c = |\rho_{ik}| \sin(\Delta \theta), \mu_s = |\rho_{ik}| \cos(\Delta \theta), \Delta \theta = \arg \left\{ a_{ru,k} \right\} - \arg \left\{ a_{ru,k} \right\} \text{ and } \epsilon_m \text{ is given by } \epsilon_0 = 1 \text{ and } \epsilon_n = 2 \text{ for } n \geq 1 \text{ [17] Eq. (26b)}.
\]

**Proof.** See App. A for the derivation of (6).

The formula for the mean SNR in (6) is compact and intuitive except for the term \( F_R \) which is easier to understand from its definition in App. A as
\[
F_R = \sum_{i=1,k=1}^{N} \sum_{k=1,j=1}^{N} \mathbb{E}\left\{ |h_{ru,i} |^2 |h_{ru,i} |^2 \right\}.
\]

Note that evaluation of \( F_R \) requires the product moment of two correlated Ricean variables. While compact expressions are given in [18] for the PDF of two correlated Ricean variables, it is important to note that these PDFs are for the special case where the LOS components are the same. Here, there is a phase shift that occurs between any two RIS elements and this assumption cannot be made. Hence, we have used the more general bivariate Ricean distribution in [17]. When the UE-RIS channel is non-LOS (correlated Rayleigh) then the complexity in all the expressions reduces considerably.

**Theorem 2.** The SNR Variance is given by
\[
\text{Var}\{\text{SNR}\} = \left( \frac{\beta^2 \kappa_d^2}{2} \left| 2 \eta_d^2 R_d a_b \right|^2 + \zeta_d \text{tr} \{ R_d^2 \} \right)
\]
\[+ \frac{\beta^2 \kappa_d^2}{2} \sqrt{\beta h_\text{br} h_{\text{ru}} AN L_{ru} \pi} \left( \frac{1}{\sqrt{\pi}} (T_{21} + T_{22} + T_{23}) - M L_d \right)
\]
\[+ \beta_d h_\text{br} h_{\text{ru}} \left( \eta_d^2 |a_d H a_d|^2 + \zeta_d A^2 \right) (N + F_{R})
\]
\[+ \left( \frac{n^2 A^2 \pi^2 L_{ru} T_{21}^2}{4} \right)
\]
\[+ \sqrt{\beta_d (\beta h_\text{br} h_{\text{ru}})} \left| 2 \sqrt{\pi} C_1 - N (N + F_{R}) \pi L_{ru} \right|
\]
\[+ (M \beta h_\text{br} h_{\text{ru}})^2 \left[ C_2 - (N + F_{R})^2 \right] \right)^2
\]
\[\text{with } L_{ru} = \frac{\zeta_{ru} L_{1/2} (-\kappa_{ru})}{\kappa_{ru}}
\]
\[L_d = \frac{\zeta_d L_{1/2}}{\kappa_{ru}} \left( \left| a_d H a_d \right|^2 \right) A^2
\]
\[T_{21} = \frac{3 B c_3^3 \sqrt{\pi}}{4} L_{ru} (-C) - \frac{2 B d_d}{A} \left\{ a_d H a_d \right\} I
\]
\[+ \frac{L_d}{2} \left( B \kappa_d |a_d H a_d|^2 \right) \left( A^2 (1 + \kappa_d) + \sqrt{\pi (M - B)} \kappa_{ru} \right)
\]
\[T_{22} = \frac{2 \eta_d}{A} \left\{ a_d H a_b \right\} I \left( \eta_d a_d H a_b \sqrt{L_d} \right)
\]
\[T_{23} = \frac{y_{ru}^2 M \sqrt{\pi}}{2} L_d
\]
\[I = \frac{3 A \sqrt{\pi}}{4} \exp \left\{ j \sqrt{A^2} - \frac{\kappa_d |a_d H a_b|^2}{2 A^2} \right\}
\]
\[\times M_{32/1}^2 \left( -\kappa_d |a_d H a_b|^2 \right) \]
\[\text{where } A \text{ is given in Theorem 1, } F_{R} \text{ is given by [7], } B = \left| R_d a_b \right|^2 / A^2, \text{ and } C = \kappa_d |a_d H a_b|^2 / A^2, M_{32/1}^2 \text{ is the Whittaker M function, } C_1 = \mathbb{E}\{ Y^3 \} \text{ and } C_2 = \mathbb{E}\{ Y^4 \}.
\]

**Proof.** See App. B and App. C for the derivation of (9).

In (9), all terms are known except for \( C_1 = \mathbb{E}\{ Y^3 \} \) and \( C_2 = \mathbb{E}\{ Y^4 \} \). To the best of our knowledge, these moments are intractable and approximations are required for these moments. Note that \( Y \) is positive, unimodal, and the sum of \( N \) random variables. A gamma distribution is commonly used to approximate such distributions, e.g., [12]. Since the first and second moments of \( Y \) are known exactly, we are able to fit a gamma approximation to \( Y \) with the correct first and second moments. Using this gamma approximation, we obtain approximations for \( \mathbb{E}\{ Y^3 \} \) and \( \mathbb{E}\{ Y^4 \} \) as presented in the following Corollary.

**Corollary.** To obtain an approximation of the SNR variance in closed form, we approximate the 3rd and 4th moments of \( Y \).
where

\[ C. \text{Benchmark Case:} \]

the integrand is smooth and rapidly decaying as by, is computationally expensive as in such scenarios the number provides a useful benchmark to evaluate the SNR trends as \( \rho \rightarrow 1 \) and \( \eta \rightarrow 1 \). The case of perfect correlation, \( |\rho_{ik}| = 1 \), provides a useful benchmark to evaluate the SNR trends as the level of correlation increases.

\[ B. \text{Case 1:} F_R \text{ for } |\rho_{ik}| < 1 \]

\[ F_R = \sum_{i=1}^{N} \sum_{k=1}^{N} \frac{|\rho_{ik}|^2}{2} \int_{0}^{2\pi} \int_{0}^{r_e - r^2} \sqrt{|a_i|^2 + r^2 + 2r |a_i| \cos(\theta - \theta_i)} \times L_{1/2} \left( -b(2|a_i|^2 + r^2 + 2r |a_i| \cos(\theta - \theta_k)) \right) d\theta d\rho, \]

where \( a_i = \eta_{ri} a_{ri,i}/(|\zeta_{ri}| \theta_i), a_k = \eta_{ri} a_{ri,k}/(|\zeta_{ri}| \theta_k), \theta_i = \angle a_{ri,i} \text{ and } \theta_k = \angle a_{ri,k}. \]

\[ C. \text{Benchmark Case:} F_R \text{ when } |\rho_{ik}| = 1 \]

For the benchmark case of maximum correlation, \( |\rho_{ik}| = 1 \), both (7) and (17) result in an indeterminate answer. However, we can use the integral form of \( F_R \) and find its result as \( |\rho_{ik}| \rightarrow 1 \) which, using the derivation in App. [F] gives

\[ F_R = \sum_{i=1}^{N} \sum_{k=1}^{N} \frac{\left( \frac{\zeta_{ri}}{\pi} \right)^2}{2} \int_{0}^{2\pi} \int_{0}^{r_e - r^2} \sqrt{|a_i|^2 + r^2 + 2r |a_i| \cos(\theta - \theta_i)} \times L_{1/2} \left( -b(2|a_i|^2 + r^2 + 2r |a_i| \cos(\theta - \theta_k)) \right) d\theta d\rho, \]

where \( a_i, \theta_i \) and \( \theta_k \) are defined in Sec. [ III-B. ] Note that the double numeric integrations required in (17) and (18) are computationally convenient as: one integral is finite range and the integrand is smooth and rapidly decaying as \( r \rightarrow \infty. \)

\[ D. \text{Special Case 1: Uncorrelated Ricean Case} \]

For independent Ricean fading, we provide exact closed form expressions for both \( \mathbb{E} \{ \text{SNR} \} \) and \( \text{Var} \{ \text{SNR} \} \). The mean SNR is given by

\[ \mathbb{E} \{ \text{SNR} \} = \left( N \sqrt{M} \zeta_{ri} \sqrt{\beta_{d} \beta_{br} \beta_{ru}} \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} M + \beta_{br} \beta_{ru} (N + F_R) \right), \]

with \( F_R \) given by

\[ F_R = \frac{\pi N (N-1)}{4} (\zeta_{ru} L_{1/2} (-\kappa_{ru}))^2. \]

This can be easily derived from Theorem 1 by noting that \( F_R \) is the sum of products of iid Ricean random variables over all \( 1 \leq i, k \leq N \) for \( i \neq k \) and \( A = \sqrt{M} \) since \( R_d = I_M \) and \( R_{ru} = I_N \).

The SNR Variance is given by

\[ \text{Var} \{ \text{SNR} \} = \left( \frac{\beta_{d}^2 M^2}{2} \frac{\zeta_{ru} L_{1/2} (-\kappa_{ru})}{N} \right) \]

\[ + \beta_{d}^{3/2} \sqrt{\beta_{br} \beta_{ru}} \sqrt{M N} \eta_{ri} \sum_{i=1}^{N} \sum_{k=1}^{N} \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]

\[ + \beta_{d} \beta_{br} \beta_{ru} \left( 4 \left( \eta_{ri}^2 |a_{d,i}^H a_{d,k}^H | \right) \right) \times L_{1/2} \left( -\kappa_{d} |a_{d}^H a_{d}|^2 \right) \]
Equations (21)-(29) follow from Theorem 2 using the substitu-
tions $A = \sqrt{M}$, $\|a_i\|^2 = M_i$, tr $\{R_n^2\} = M_i$ and the version of $F_R$ given in (20). A consequence of having uncorrelated UE-BS and UE-RIS channels, is that the expectations $\mathbb{E}\{Y^3\}$ and $\mathbb{E}\{Y^4\}$ are known exactly and these are given by (28) and (29) respectively.

**E. Special Case 2: Correlated Rayleigh Case**

We obtain mean SNR and SNR variance expressions for correlated Rayleigh channels $h_d$ and $h_{ru}$ by setting $\kappa_d = \kappa_{ru} = 0$.

1) **Mean SNR:** Note that when $\kappa_d = 0$, $\zeta_d = 1$ and $L_{1/2}(-\kappa_{ru}) = 1$. Similarly when $\kappa_d = 0$, $\zeta_d = 1$ and $L_{1/2}(-\frac{|a_i|^2}{\beta_d^2}) = 1$. As such, the second term in (6) reduces down to the second term in [16, Eq. (8)]. The third term can be reduced to its correlated Rayleigh form as shown in [16, Eq. (8)] by reducing $F_R$ to (31) (see App. E). The final form after reducing all of the terms in (6) results in the mean SNR expression in [16, Eq. (8)]; given below for completeness:

**Theorem 3.** The mean SNR when $h_d$ and $h_{ru}$ are correlated Rayleigh channels is given by

$$
\mathbb{E}\{\text{SNR}\} = \left(\beta_d M + \frac{N\pi \sqrt{\beta_d \beta_{ru}}}{2} + \beta_{br} \beta_{ru} M(N + F)\right) \bar{\tau},
$$

(30)

with $F$ given by

$$
F = \sum_{i=1}^{N} \sum_{k=1}^{N} \frac{\pi}{4} \left(1 - |\rho_{ik}|^2\right)^{2} 2F_1\left(\frac{3}{2}; \frac{3}{2}; 1; |\rho_{ik}|^2\right),
$$

(31)

and $A = \|R_d^{1/2}a_b\|^2$, where $2F_1(\cdot)$ is the Gaussian hypergeometric function and $\rho_{ij} = (R_{ru})_{ij}$.

2) **SNR Variance:** In addition to the steps undertaken in [III-E1], we further note that $\eta_d = \eta_{ru} = 0$. This eliminates many of the terms in (9) of Theorem 2. Using App. E to collapse $F_R$ down to its correlated Rayleigh form, we obtain the final SNR variance expression for correlated Rayleigh channels, consistent with that given in [16, Eq. (10)] and given below for completeness:

**Theorem 4.** The SNR variance when $h_d$ and $h_{ru}$ are corre-

lated Rayleigh channels is given by

$$
\text{Var}\{\text{SNR}\} = \left(\beta_d^2 tr\{R_d^2\} + \beta_d^{3/2} \sqrt{\beta_d \beta_{ru}} N \pi (B - MA) + \beta_d \beta_{ru} A^2 \frac{4(N + F) - N^2 \pi^2}{4}\right)
$$

$$
+ MA \sqrt{\beta_d \beta_{ru}} \frac{3/2}{2} \left(2\pi C_1 - N(N + F)\pi\right) + (M \beta_{ru})^2 (C_2 - (N + F)^2) \bar{\tau}^2,
$$

(32)

where $B = MA + a_k^2 R_d^2 a_k / 2A$, $F$ is given by (31). $A$ is given in Theorem 1 and $C_1 = \mathbb{E}\{Y^3\}$, $C_2 = \mathbb{E}\{Y^4\}$.

**Corollary.** To obtain an SNR variance approximation in closed form, we approximate the $3^{rd}$, $4^{th}$ moments of $Y$ by

$$
\mathbb{E}\{Y^3\} = b^3 a \prod_{k=1}^N (k + a), \quad \mathbb{E}\{Y^4\} = b^4 a \prod_{k=1}^N (k + a) \quad (33)
$$

with

$$
a = \frac{N^2 \pi}{4(N + F) - N^2 \pi^2}, \quad b = \frac{2}{N \sqrt{\pi}} (N + F - \frac{N^2 \pi}{4}).
$$

(33)

**IV. PERFORMANCE INSIGHTS BASED ON $\mathbb{E}\{\text{SNR}\}$**

Note that the first term in the mean SNR in (6) is influenced by variants of the function $q(\alpha, x) \triangleq L_{1/2}(-\alpha x) / \sqrt{1 + x}$ for $x \in \{\kappa_{ru}, \kappa_d\}$, $\alpha \geq 0$, where the factor of $1 / \sqrt{1 + x}$ arises from the $c_{ru}$ and $c_d$ terms. Hence, we study the behaviour of $q(\alpha, x)$ before developing performance insights based on the mean SNR.

**A. Behaviour of $L_{1/2}(-\alpha x) / \sqrt{1 + x}$**

Using [19, Eq. (13.6.9)] the Laguerre function can be rewritten in terms of the confluent hypergeometric function, $F_1$, as

$$
L_{1/2}(-\alpha x) = F_1\left(-\frac{1}{2}; 1; \alpha x\right).
$$

(34)

Using the series expansion for $F_1$ [19, Eq. (13.1.2)] and the Maclaurin series expansion of $1 / \sqrt{1 + x}$, we have the following expansion for $q(\alpha, x)$,

$$
q(\alpha, x) = 1 + \alpha x - \frac{\alpha^2 x^2}{16} + \cdots \left(1 - \frac{x}{2} + \frac{3x^2}{8} - \cdots\right)
$$

$$
= 1 + \frac{\alpha - 1}{2} x + \frac{6 - 4\alpha - \alpha^2}{16} x^2 + \cdots
$$

First, we look at the behaviour near the origin. Noting that $q(\alpha, 0) = 1$, then for $\alpha \geq 1$, $q(\alpha, x)$ is increasing in $x$ and for $\alpha < 1$, $q(\alpha, x)$ is decreasing in $x$.

Next, we look at the behaviour as $x \to \infty$. Using the asymptotic behaviour of $F_1$ [19, Eq. (13.1.5)], we have

$$
q(\alpha, x) \sim 2 \sqrt{\frac{\alpha x}{\pi(1 + x)}} \left(1 + \frac{1}{4\alpha x}\right)
$$

(35)

$$
\to 2 \sqrt{\frac{\alpha x}{\pi}} \quad \text{as} \ x \to \infty.
$$

(36)

From (35), we see that as $x \to \infty$, $q(\alpha, x) \geq q(\alpha, 0) = 1$ for $\alpha \geq \pi/4$ and $q(\alpha, x) < q(\alpha, 0) = 1$ for $\alpha < \pi/4$. Differentiating (35) and simplifying gives

$$
\frac{dq(\alpha, x)}{dx} \approx \frac{1}{2\alpha x^{3/2} \sqrt{1 + x}} \left(\alpha x + \frac{1}{1 + x} - \frac{1}{2}\right),
$$

(37)
for large values of \( x \). From (37), we make the following observations. As \( x \to \infty \), \( \frac{d\eta(x)}{dx} < 0 \) for \( \alpha < 1/2 \) and \( \frac{d\eta(x)}{dx} > 0 \) for \( \alpha \geq 1/2 \).

Collating these properties, we obtain the following result:

**Result 1.** The main characteristics of \( \eta(x) \) are given by

\[
q(\alpha, x) \begin{cases} 
\text{increases near the origin,} & \text{for } \alpha \geq 1, \\
\text{positive gradient as } x \to \infty, & \text{for } \alpha \geq 1/2, \\
\text{negative gradient as } x \to \infty, & \text{for } \alpha < 1/2. 
\end{cases}
\]

\[
\frac{d\eta(x)}{dx} = \begin{cases} 
\geq 1 \text{ as } x \to \infty, & \text{for } \alpha \geq \pi/4, \\
< 1 \text{ as } x \to \infty, & \text{for } \alpha < \pi/4.
\end{cases}
\]

**B. Effect of \( \kappa_{\text{ru}} \) on \( \mathbb{E}\{\text{SNR}\} \)**

Only the first and third terms in (6) are affected by \( \kappa_{\text{ru}} \). The first term contains \( q(1, \kappa_{\text{ru}}) \) so is increasing with \( \kappa_{\text{ru}} \) from Result 1. In the third term, \( \kappa_{\text{ru}} \) affects the mean SNR via the \( F_R \) expression. Applying Hölder’s inequality to \( F_R \) in (8) gives \( F_R \leq N(N - 1) \). This upper bound is achieved when \( \kappa_{\text{ru}} \to \infty \). Hence, we conclude that increasing \( \kappa_{\text{ru}} \) improves the mean SNR.

**C. Effect of \( \kappa_{\text{d}} \) on \( \mathbb{E}\{\text{SNR}\} \)**

Only the first term in (9) is affected by \( \kappa_{\text{d}} \) through the expression

\[
\zeta_3 L_{1/2} \left( -\frac{\kappa_{\text{d}}}{A^2} \left| \frac{a_{\text{d}}^H a_{\text{d}}}{A^2} \right|^2 \right) = q \left( \left| \frac{a_{\text{d}}^H a_{\text{d}}}{A^2} \right|^2, \kappa_{\text{d}} \right).
\]

From Result 1, this expression increases with \( \kappa_{\text{d}} \) when \( \left| a_{\text{d}}^H a_{\text{d}} \right| > A \), decreases when \( \left| a_{\text{d}}^H a_{\text{d}} \right| < \sqrt{2A} \) and has a more complex behavior in-between.

This pattern can be explained by the fact that \( \left| a_{\text{d}}^H a_{\text{d}} \right| \) measures the alignment of the RIS-BS channel, \( a_{\text{d}} \), with the LOS component of the direct path, \( a_{\text{d}} \), while \( A = \| R_{\text{d}} \|_{1/2} \) measures the alignment of \( a_{\text{d}} \) with the scattered component of the direct path. Hence, when the RIS-BS aligns strongly with the direct LOS path then \( \kappa_{\text{d}} \) improves the SNR. Conversely, when the RIS-BS aligns strongly with the direct scattered channel then increasing \( \kappa_{\text{d}} \) reduces the SNR.

The dominant effect here is the \( \left| a_{\text{d}}^H a_{\text{d}} \right| < \sqrt{2A} \) case, where \( \kappa_{\text{d}} \) decreases the mean SNR. This is because it is unlikely for two independent steering vectors to strongly align, whereas \( a_{\text{d}} \) can align with \( R_{\text{d}} \) in several ways as the correlation matrix is usually full-rank (see [16]).

**D. Effect of \( \rho_{\text{ru}} \) on \( \mathbb{E}\{\text{SNR}\} \)**

The effect of correlation in the UE-RIS channel, \( \rho_{\text{ru}} \), on the mean SNR is confined to the variable \( F_R \) in (6). Identifying the behavior of \( F_R \) with respect to \( \rho_{\text{ru}} \) is very difficult due to the oscillations in the series expansion given in (7) caused by the \( \cos(n\theta) \) term.

However, when \( \kappa_{\text{ru}} = 0 \) we have the correlated Rayleigh case and \( F_R \) becomes \( F \) in (31) which increases with correlation (see [16]). Hence, we conjecture the same broad trend here, so that the mean SNR usually benefits from increasing correlation in \( h_{\text{ru}} \).

It is worth noting that the majority of the existing literature does not have the complication of the \( \cos(n\theta) \) term in the bivariate Ricean PDF. This is due to the assumption that both of the Ricean variables have identical LOS components (see [13] for example). However, this simplifying assumption is not valid here and the more complex version in [17] is required.

**E. Effect of \( \rho_{\text{d}} \) on \( \mathbb{E}\{\text{SNR}\} \)**

Only variable \( A \) in the first term of (9) is affected by \( \rho_{\text{d}} \). It is shown in [16, Sec. IV.B] that as \( \rho_{\text{d}} \to 1 \), we can usually expect \( A \leq \sqrt{M} \) for large \( M \). In contrast, when \( \rho_{\text{d}} = 0 \), we have \( A = \sqrt{M} \). Hence, the mean SNR benefits from low correlation in the UE-BS link.

**F. Favourable and Unfavourable Conditions**

From Sec. IV.B - Sec. IV.E, low correlation and low K-factor in the UE-BS link along with a high K-factor in the UE-RIS link tend to improve \( \mathbb{E}\{\text{SNR}\} \). Hence, we define the **favourable channel scenario** as an iid Rayleigh channel between UE and BS and pure LOS between UE and RIS. Conversely, the **unfavourable channel scenario** comprises an iid Rayleigh UE-RIS channel and a LOS UE-BS channel.

Using the analysis in Sec. IV the mean SNR in the favourable channel scenario is given by

\[
\mathbb{E}\{\text{SNR}_{\text{fav}}\} = \left( \beta_{\text{d}}M + N\sqrt{M\pi\sqrt{\beta_{\text{d}}\beta_{\text{ru}}}} \right) \tilde{\tau}, \tag{38}
\]

while the mean SNR in the unfavourable channel scenario is

\[
\mathbb{E}\{\text{SNR}_{\text{unfav}}\} = \left( \beta_{\text{d}}M + N\sqrt{\pi\sqrt{\beta_{\text{d}}\beta_{\text{ru}}}} \right) \tilde{\tau} + \beta_{\text{ru}} M \left( N + \frac{\pi N(N - 1)}{4} \right) \tilde{\tau}, \tag{39}
\]

using the result for \( F_R \) for uncorrelated Rayleigh fading (see [16, Eq. (14)]).

Next we consider the relative difference between these two scenarios for large RIS sizes. Defining the gain

\[
\text{Gain}_{\text{fav- unfav}} = \frac{\mathbb{E}\{\text{SNR}_{\text{fav}}\} - \mathbb{E}\{\text{SNR}_{\text{unfav}}\}}{\mathbb{E}\{\text{SNR}_{\text{unfav}}\}}, \tag{40}
\]

it is straightforward to show that

\[
\lim_{N \to \infty} \text{Gain}_{\text{fav- unfav}} = \frac{4 - \pi}{\pi} \approx 27.32%.
\]

Hence, for large RIS, the asymptotic relative gain between the channel scenarios is approximately 27.32%.

In order to find the maximum gain, we rewrite (40) as

\[
\text{Gain}_{\text{fav- unfav}} = \frac{N^2 D_1 + N D_2}{N^2 D_3 + N D_4 + D_5}. \tag{41}
\]

Differentiating (41) with respect to \( N \) is elementary and allows the maximum to be obtained. Details are omitted but results are shown in Sec. V.

**V. RESULTS**

We present numerical results to verify the analysis in Sec. IV. Firstly, note that we do not consider cell-wide
averaging as the focus is on the SNR distribution over the fast fading. Furthermore, the relationship between the SNR and the path gains, $\beta_d, \beta_{ru}$ and $\beta_{ru}$, is straightforward, as shown in (9). Hence, we present numerical results for fixed link gains. In particular, since the RIS-BS link is LOS, we assume $\beta_{ru} = d_{ru}^2$ where $d_{ru} = 20m$. Next, for simplicity, $\beta_d = \beta_{ru} = 0.69$. This was chosen to give the 95%-ile of the SNR distribution as 25 dB in the baseline case of moderate channel correlation and identical Ricean K-factors for the LOS and scattered paths (defined as $\rho_d = \rho_{ru} = 0.7, \kappa_d = \kappa_{ru} = 1$), with $M = 32$ BS antennas and $N = 64$ RIS elements.

As stated in Sec. II-A, the steering vectors for $H_{ay}$ are not restricted to any particular form. However, for simulation purposes, we will use the VURA model as outlined in [21], but in the $y-z$ plane with equal spacing in both dimensions at both the RIS and BS. The $y$ and $z$ components of the steering vector at the BS are $a_{y}$ and $a_{z}$, which are defined by:

$$[1, e^{j2\pi d_y \sin(\theta_y)} \sin(\omega_y), \ldots, e^{j2\pi d_y (M_y-1) \sin(\theta_y)} \sin(\omega_y)]^T$$

and

$$[1, e^{j2\pi d_z \cos(\theta_z)} \sin(\omega_z), \ldots, e^{j2\pi d_z (M_z-1) \cos(\theta_z)} \sin(\omega_z)]^T,$$

respectively. Similarly, at the RIS, $a_{y}$ and $a_{z}$ are defined by:

$$[1, e^{j2\pi d_y \sin(\theta_y)} \sin(\omega_y), \ldots, e^{j2\pi d_y (N_y-1) \sin(\theta_y)} \sin(\omega_y)]^T$$

and

$$[1, e^{j2\pi d_z \cos(\theta_z)} \sin(\omega_z), \ldots, e^{j2\pi d_z (N_z-1) \cos(\theta_z)} \sin(\omega_z)]^T,$$

respectively, where $M = M_yM_z$, $N = N_yN_z$ with $M_y, M_z$ being the number of antenna columns and rows at the BS and $N_y, N_z$ being the number of columns and rows of RIS elements, $d_y = 0.5$, $d_z = 0.2$, where $d_y$ and $d_z$ are in wavelength units. The steering vectors at the BS and RIS are then given by:

$$a_h = a_{b,y} \otimes a_{b,z}, \quad a_r = a_{r,y} \otimes a_{r,z}, \quad (42)$$

respectively. $\theta_A$ and $\omega_A$ are elevation/azimuth angles of arrival (AOAs) at the BS and $\theta_D, \omega_D$ are the corresponding angles of departure (AODs) at the RIS. The elevation/azimuth angles are selected based on the following geometry representing a range of LOS $H_{ay}$ links with less elevation variation than azimuth variation: $\theta_D \sim U[0^\circ, 180^\circ]$, $\omega_D \sim U[-90^\circ, 90^\circ]$, $\theta_A = 180^\circ - \theta_D$, $\omega_A = 90^\circ - \theta_D$. For all results in this paper we use a single sample from this range of angles given by $\theta_D = 77.1^\circ$, $\omega_D = 19.95^\circ$, $\theta_A = 109.9^\circ$, $\omega_A = -29.9^\circ$.

For the LOS components in the UE-BS and UE-RIS channels, the $y$ and $z$ components of the steering vector at the BS are $a_{y}$ and $a_{z}$, which are defined by:

$$[1, e^{j2\pi d_y \sin(\theta_A \omega_A)} \sin(\omega_A), \ldots, e^{j2\pi d_y (M_y-1) \sin(\theta_A \omega_A)} \sin(\omega_A)]^T$$

and

$$[1, e^{j2\pi d_z \cos(\theta_A \omega_A)} \sin(\omega_A), \ldots, e^{j2\pi d_z (M_z-1) \cos(\theta_A \omega_A)} \sin(\omega_A)]^T,$$

respectively. Similarly, at the RIS, $a_{ru,y}$ and $a_{ru,z}$ are defined by:

$$[1, e^{j2\pi d_y \sin(\theta_D \omega_D)} \sin(\omega_D), \ldots, e^{j2\pi d_y (N_y-1) \sin(\theta_D \omega_D)} \sin(\omega_D)]^T$$

and

$$[1, e^{j2\pi d_z \cos(\theta_D \omega_D)} \sin(\omega_D), \ldots, e^{j2\pi d_z (N_z-1) \cos(\theta_D \omega_D)} \sin(\omega_D)]^T,$$

respectively. Therefore, the LOS components in the UE-BS and UE-RIS channels are given by:

$$a_d = a_{y} \otimes a_{z}, \quad a_{ru} = a_{ru,y} \otimes a_{ru,z}, \quad (43)$$

where $\theta_{D,A}$ and $\omega_{D,A}$ are the corresponding angles of departure (AODs) for the UE at the BS and $\theta_{D,r}, \omega_{D,r}$ are the corresponding angles of departure (AODs) for the UE at the RIS.

For all results in this paper we use a single sample of angles from $\theta_{A,d} \sim U(0, 180^\circ)$, $\omega_{A,d} \sim U(-90^\circ, 90^\circ)$ which are given by $\theta_{D,r} = 80.94^\circ, \omega_{D,r} = -64.35^\circ, \theta_{A,d} = 71.95^\circ, \omega_{A,d} = 25.1^\circ$.

Note that all of these parameter values and variable definitions are not altered throughout the results and figures, unless specified otherwise.

A. Approximate CDF for SNR

It is known that the SNR of a wide range of fading channels can be approximated by a mixture gamma distribution [22]. Also, as discussed in Sec. III, it is well-known that a single gamma approximation is often reasonable for a sum of a number of positive random variables [12]. Motivated by this, we approximate the SNR in (5) by a single gamma variable.

The shape parameter of a gamma approximation to the SNR is given by $\kappa_\gamma = \frac{\mathbb{E}\{SNR\}}{\text{Var}\{SNR\}}$ and the scale parameter is $\theta_\gamma = \sqrt{\mathbb{E}\{SNR\}} \text{Var}\{SNR\}$, where $\mathbb{E}\{SNR\}$ and $\text{Var}\{SNR\}$ are given in Sec. III. Using these values of $\kappa_\gamma, \theta_\gamma$, the analytical and simulated SNR CDFs are shown in Fig. 2 for $N = 16$ and $N = 64$, both with $\rho_{ru} = \rho_d \in \{0, 0.7, 0.95\}$ and $\kappa_d = \kappa_{ru} \in \{1, 10^3\}$. When computing the analytical SNR CDFs, for $\rho_{ru} = \rho_d = 0$, (19) and (21) were used but with $F_R, C_{\rho_{d,u}}, C_{\rho_{u}}$ presented in Sec. III-D. For $\rho_{ru} = \rho_d = 0.7, (6)$ and (9) were used. For $\rho_{ru} = \rho_d = 0.95, (6)$ and (9) were also used but with $F_R$ given by (17).

FIG. 2: Simulated and analytical CDFs for $N \in \{16, 64\}$, both with $\rho_{ru} = \rho_d \in \{0, 0.7, 0.95\}$ and $\kappa_d = \kappa_{ru} \in \{1, 6\}$

As expected, there is a very good agreement between the simulated and analytical SNR CDFs when $\rho_{ru} = \rho_d = 0$ due to exact mean SNR and SNR variance expressions being available for all $\kappa_d$ and $\kappa_{ru}$. For higher correlation, we can see that the agreement deviates slightly in the lower and upper tails when the K-factor is small. This is due to the approximation made by fitting a gamma distribution using the
3rd and 4th moments of $Y$. For higher K-factors, the 3rd and 4th moments of $Y$ are better approximated due to the UE-RIS channel being dominated by the LOS path, which will cause $Y$ to be close to deterministic. In such scenarios, the gamma distribution provides an even better representation of the UL SNR. In general, for all correlation and K-factor scenarios, the gamma distribution provides a good representation of the UL SNR even in high correlation scenarios.

### B. The effects of $\rho_d, \rho_{ru}, \kappa_d, \kappa_{ru}$ and Asymptotic Results

Here, we verify the performance insights based on $E\{\text{SNR}\}$ described in Sec. [IV](#). Fig. [3](#) gives the SNR simulations and analyses for various correlation and K-factor combinations in $h_d$ and $h_{ru}$. As a general observation, it is apparent that the analysis agrees with the simulations for every scenario.

Inspection of Fig. [3](#) reveals that increasing $\kappa_d$ has a negative impact on the mean SNR as predicted by the analysis. The analysis also predicted that correlation in the direct channel $\rho_d$ negatively impacts performance, which is also seen in Fig. [3](#). The best performance occurs for $\rho_d = 0, \rho_{ru} = 1, \kappa_d = 1, \kappa_{ru} = 10^3$, which supports the favourable channel scenario claim in the analyses. Finally, the worst performance is observed when $\rho_d = \rho_{ru} = 0, \kappa_d = 10^3, \kappa_{ru} = 1$, supporting the unfavourable channel scenario claim in Sec. [IV](#).

Furthermore, although not visible, scenarios where the channel has a very high K-factor will yield very similar curves regardless of the correlation in that channel. For example, the curve for $\rho_d = 0, \rho_{ru} = 1, \kappa_d = 10^3, \kappa_{ru} = 1$ is very similar to the curve for $\rho_d = 1, \rho_{ru} = 1, \kappa_d = 10^3, \kappa_{ru} = 1$. This observation is not unusual since the channel is dominated by the LOS path and is thus not significantly impacted by scattering.

![Fig. 3](#): Simulated and analytical mean results for SNR for correlation scenarios: $\rho_{ru} = \rho_d \in \{0, 1\}, \rho_{ru} = 1, \rho_d = 0$ and K-factor scenarios: $\kappa_d \in \{1, 10^3\}, \kappa_{ru} \in \{1, 10^3\}$.

Fig. [4](#) shows the accuracy of the SNR variance approximation. As expected, for scenarios where $h_d$ and $h_{ru}$ are uncorrelated, we note perfect agreement between the simulations and analyses. As the K-factor in the UE-RIS channel, $\kappa_{ru}$, increases, the variance is reduced, which becomes significant when both $\kappa_{ru}$ and $\kappa_d$ are very large. This effect is also observed by the change in the CDF spread in Fig. [4](#).

For scenarios where the K-factor is low, the accuracy of the agreement between simulation and analyses is a consequence of the approximations of the 3rd and 4th moments of $Y$ only, since all of the other terms in the expression can be expressed in closed form. From Fig. [4](#) it can be seen that as the number of RIS elements $N$ increases, the approximation worsens for highly correlated scenarios with $\kappa_{ru} = 1$ and $\kappa_d = 10^3$. However, for the identical correlation scenarios with $\kappa_{ru} = 10^3$ and $\kappa_d = 1$, the approximation improves. Note that $Y$ is the sum of amplitudes of the correlated elements in $h_{ru}$. When the K-factor is very high, then $E\{Y^3\} \approx Y^3$ and $E\{Y^4\} \approx Y^4$, hence the observed improvement in the approximation.

The convergence of the various curves in Fig. [4](#) supports the claim in the analyses that increasing the number of RIS elements reduces the negative impacts of $\kappa_d$ and $\rho_d$ in the UE-BS channel. This is seen in the curves relating to $\rho_{ru} = \rho_d = 1$ and $\rho_{ru} = 1, \rho_d = 0$ as well as the curves relating to $\kappa_{ru} = \kappa_d = 1$ and $\kappa_{ru} = 1, \kappa_d = 10^3$.

Finally, we verify the results regarding the relative gain given in Sec. [IV](#). The relative gain improvement in (40), when transitioning from unfavourable to favourable channel scenarios, is simulated for a range of different link gains $\beta_d, \beta_{ru}, \beta_{ru}$ and shown in Fig. [5](#). As can be seen, all of the different link gain scenarios asymptotically approach $(4-\pi)/\pi$.
as per the analysis and the saturation rate is dependent on the link gain values. Also apparent is that having a large number of RIS elements does not always yield the maximum relative gain. The vertical lines represent the number of RIS elements required to achieve the maximum possible gain, as detailed in Sec. [IV-F] In general, the simulation and analysis agree.

VI. CONCLUSION

We derive an exact closed form expression for the mean SNR of the optimal single user RIS design where spatially correlated Ricean fading is assumed for the UE-BS and UE-RIS channels and the RIS-BS channel is LOS. We also provide an accurate approximation of the SNR variance and a gamma approximation to the CDF of the SNR. Furthermore, we show that when the UE-RIS and UE-BS channels are correlated Rayleigh, both the mean SNR and SNR variance expressions under correlated Ricean channels can be reduced to the expressions given in [16]. The analysis presented offers new insight into how spatial correlation and the Ricean K-factor impact the mean SNR and scenarios in which we would expect high and low SNR performance. Specifically, we show that the mean SNR benefits from having a high correlation and a high K-factor in UE-RIS channel while the UE-BS channel has low correlation and a low K-factor. These correlation and K-factor extremes represent favorable channel scenarios while unfavorable channel scenarios occur at the opposite ends of these extremes. To this end, we show that the asymptotic gain achievable when transitioning between unfavourable and favourable environments is $(4 - \pi)/\pi$.

APPENDIX A

DERIVATION OF MEAN SNR

Expanding (5) gives,

$$\text{SNR} = \beta_d \left| h_d^H \bar{h}_d \right|^2 + 2 \sqrt{\beta_d} \Re \{ \alpha h_d^H a_d \} + |\alpha|^2 M \right \} \bar{\tau} \triangleq (S_1 + S_2 + S_3) \bar{\tau}.$$

We compute $\mathbb{E} \{ \text{SNR} \}$ by computing the expectation of each term in the expression above.

**Term 1:** Expanding $S_1$,

$$S_1 = \beta_d \left( \eta_d^2 a_d^H a_d + 2 \eta_d \zeta_d \Re \{ a_d^H R_d^{1/2} u_d \} + \zeta_d^2 u_d^H R_d u_d \right).$$

Using [23] Eq. (9)) and since $u_d \sim CN(0, I)$, then

$$\mathbb{E} \{ S_1 \} = \beta_d \left( \eta_d^2 M + \zeta_d^2 \text{tr} \{ R_d \} \right) = \beta_d M. \quad (44)$$

**Term 2:** Substituting $\alpha$ from Sec. [II-B] into $S_2$,

$$\mathbb{E} \{ S_2 \} = 2 \mathbb{E} \{ \beta_d \bar{h}_d \sum_{n=1}^{N} \bar{h}_{ru,n} \} \mathbb{E} \{ a_d^H \bar{h}_d \}$$

$$= 2 \mathbb{E} \{ \beta_d \bar{h}_d \} \mathbb{E} \{ Y \} \mathbb{E} \{ a_d^H \bar{h}_d \} \,.$$

Firstly, we can rewrite the definition of $\bar{h}_{ru}$ in Sec. [II-A] as $\bar{h}_{ru,i} = X_1 + j X_2$, where $X_1 \sim \mathcal{N}(\eta_{ru} \Re \{ a_{ru} \}), (\zeta_{ru}^2/2) \mathbb{I}$ and $X_2 \sim \mathcal{N}(\eta_{ru} \Im \{ a_{ru} \}), (\zeta_{ru}^2/2) \mathbb{I}$. Then using the moments of a Ricean RV [24 Eq. (2.3-58)] and a confluent hypergeometric to Laguerre polynomial relation [19 Eq. (13.6.9)], we have

$$\mathbb{E} \{ Y \} = \frac{N \zeta_{ru} \sqrt{\pi}}{2} L_{1/2}(-\kappa_{ru}).$$

Similarly,

$$\mathbb{E} \{ a_d^H \bar{h}_d \} = \frac{A \eta_d \sqrt{\pi}}{2} L_{1/2}(-\kappa_d |a_d^H a_d|^2),$$

where $A = \left\| R_d^{1/2} a_d \right\|$. Therefore,

$$\mathbb{E} \{ S_2 \} = \mathbb{E} \{ a_d^H \bar{h}_d \},$$

$$\mathbb{E} \{ S_2 \} = \frac{N \zeta_{ru} \sqrt{\pi}}{2} \sum_{n=1}^{N} \mathbb{E} \{ a_d^H \bar{h}_d \} \,.$$

**Term 3:** Since $|\psi| = 1$ (where $\psi$ is given in Sec. [II-B]) we have $S_3 = M \beta_{ru} \beta_{ru} Y^2$ and expanding $Y$ gives

$$\mathbb{E} \{ Y^2 \} = N + \sum_{i=1}^{N} \sum_{k=1}^{N} \mathbb{E} \{ \bar{h}_{ru,i} \bar{h}_{ru,k} \} \,.$$

Let $r_i = \left\| \bar{h}_{ru,i} \right\|, r_k = \left\| \bar{h}_{ru,k} \right\|, a = \eta_{ru}, \sigma_{ru} = \zeta_{ru}^2/2, \rho_{ik} = \left\| \mathbf{R}_{ru} \right\|_{1,k}, \text{ then the joint moment of two correlated Ricean RVs } r_i, r_k \text{ is given by [17 Eq. (27)]},

$$\mathbb{E} \{ r_i r_k \} = \frac{1 - \rho_{ik}^2}{1 + \kappa_{ru}} \exp \left\{ \frac{2\kappa_{ru} - 2\mu \kappa_{ru}}{1 - |\rho_{ik}|^2} \right\} \times \sum_{m=0}^{\infty} \sum_{n=0}^{\kappa_{ru}} \epsilon_n \cos(\phi) \rho_{ik}^{2m-n} \left( \frac{\kappa_{ru}(1 + \mu \kappa_{ru} - 2\mu)\kappa_{ru}^2}{1 - |\rho_{ik}|^2} \right)^n \times \Gamma^2 \left( m + \frac{3}{2} \right) \text{I}_F \left( m + \frac{3}{2}, 2n + 1, \kappa_{ru}(1 + \mu \kappa_{ru} - 2\mu)\kappa_{ru}^2 \right)$$

where $I_F(\cdot)$ is the confluent hypergeometric function, $\phi = \arg \{ 1 + \rho_{ik}^2 \mu \kappa_{ru} - 2\mu \kappa_{ru} \rho_{ik} \} + j(1 - \rho_{ik}^2 \kappa_{ru} \mu \kappa_{ru})$, $\mu = \kappa_{ru} \cos(\Delta \theta), \mu = \kappa_{ru} \sin(\Delta \theta), \Delta \theta = \arg \{ a_{ru,i} \} - \arg \{ a_{ru,k} \}$ and $\epsilon_n$ is given in Theorem 1 (see [17 Eq. (26b)]).

Finally, we substitute the final form of $\mathbb{E} \{ r_i r_k \}$ into the
double summation of \( \mathbb{E}\{ Y^2 \} \) and denote this as \( F_R \). Therefore,
\[
\mathbb{E}\{ S_2 \} = M \beta \rho^2 (N + F_R),
\]
where \( F_R \) is given by \( (7) \). Combining \( (44), (45) \) and \( (46) \) completes the derivation.

**APPENDIX B**

**DERIVATION OF SNR VARIANCE**

To compute the variance we take the square of \( \{ 5 \} \) giving
\[
\text{SNR}^2 = \left( \beta_d^2 \left( \hat{h}_d^H \hat{h}_a \right)^2 + 4 \beta_d^3/2 \hat{h}_d^H \hat{h}_a \mathbb{R} \left\{ \alpha \hat{H}_d^H a_b \right\} \right)^2 + 2 \beta_d M |\alpha|^2 \hat{h}_d^H \hat{h}_a + 4 \beta_d \mathbb{R} \left\{ \alpha \hat{H}_d^H a_b \right\}^2 + 4 \sqrt{\beta_d} M |\alpha|^2 \mathbb{R} \left\{ \alpha \hat{H}_d^H a_b \right\} + |\alpha|^4 \left( M^2 \right)^{-1}
\]
\[
\triangleq (T_1 + T_2 + T_3 + T_4 + T_5 + T_6)^2.
\]

**Term 1:** \( T_1 \) can be alternately written as \( T_1 = \beta_d \left\| \hat{h}_a \right\|_2^4 \). Using \( (29) \) Eq. \((5)\), we have
\[
\mathbb{E}\{ T_1 \} = \beta_d^2 \left( M^2 + 2 \eta_\delta x/2 \left\| R_{1/2} a_b \right\|_2^2 \right) + \zeta_4 \text{tr} \{ R_a \}^2.
\]

**Term 2:** Substituting \( \alpha \) from Sec. \( \text{II-B} \) into \( T_2 \).
\[
\mathbb{E}\{ T_2 \} = 4 \beta_d^{3/2} \sqrt{\beta \rho \beta_d} \mathbb{E}\{ Y \} \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \} = 2 \zeta_4 \beta_d^{3/2} \sqrt{\beta \rho \beta_d} \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \},
\]
where the expectation of \( Y \) is found in App. A. To compute \( \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \} \), we introduce the following variables:
\[
Q = \mathbb{P}^H R_a P \text{ and } p_1 = \mathbb{R}_{1/2} a_b / A \text{ where } p_1 \text{ is the first column of any arbitrary orthonormal matrix } \mathbb{P}, A = \left\| R_{1/2} a_b \right\|_2^2.
\]

Then \( \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \} \) can be rewritten as,
\[
\mathbb{E}\{ \hat{h}_d^H \hat{h}_d \} = \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \} = \mathbb{E}\{ \mathbb{P}^H R_a \mathbb{P} \} \mathbb{E}\{ \mathbb{P}^H R_a \mathbb{P} \} = \left( \mathbb{P}^H R_a \mathbb{P} \right)^H \mathbb{P}^H R_a \mathbb{P}
\]
\[
= A \sum_{s=1}^{M} \sum_{t=1}^{M} \zeta_4 s Q_{st} \mathbb{E}\{ x_s^H x_t | \zeta a x_1 + b \}
\]
\[
+ 2 \text{Re} \left\{ \sum_{s=1}^{M} \sum_{t=1}^{M} \zeta_4 s Q_{st} s^H \mathbb{E}\{ x_t | \zeta a x_1 + b \} \right\}
\]
\[
+ \sum_{s=1}^{M} \sum_{t=1}^{M} \zeta_4 s Q_{st} d^H d_t \mathbb{E}\{ |\zeta a x_1 + b| \}
\]
\[
\triangleq A (T_{21} + T_{22} + T_{23}).
\]

Computing \( (50) \) and substituting it into \( (49) \) completes the derivation for \( \mathbb{E}\{ T_2 \} \).

Sub-Term 1: Notice that \( T_{21} \) is non zero iff \( s = t \). So,
\[
T_{21} = Q_{11} \mathbb{E}\{ |\zeta a x_1 + b| \}
\]
\[
+ \mathbb{E}\{ |\zeta a x_1 + b| \} (\text{tr} \{ Q \} - Q_{11})
\]
\[
= B \zeta_4 \mathbb{E}\{ |\zeta a x_1 + b| \} - 2 \text{Re} \{ b^H (\zeta a x_1 + b) |\zeta a x_1 + b| \}
\]
\[
+ |b|^2 |\zeta a x_1 + b| \} + \mathbb{E}\{ |\zeta a x_1 + b| \} (M - B),
\]

since \( \text{tr} \{ Q \} = M \) and \( B = Q_{11} = \|R_a a_b\|^2 / A^2 \). The closed form solution for \( I \triangleq \mathbb{E}\{ |\zeta a x_1 + b| \} \) is found in App. C. Using this result, along with the 1st and 3rd moments of a Ricean RV and some algebraic simplification,
\[
T_{21} = \frac{3B \zeta_4 \mathbb{E}\{ |\zeta a x_1 + b| \}^2}{4} - \frac{2 \mathbb{E}\{ |\zeta a x_1 + b| \}^2}{A^2} + \mathbb{E}\{ |\zeta a x_1 + b| \} (M - B),
\]

where \( C = \kappa_d \| a_b \|_2^2 / A^2 \).

Sub-Term 2: The terms inside the real operator in \( T_{22} \) can be written as,
\[
\sum_{s=1}^{M} \mathbb{E}\{ |\zeta a x_1 + b| \} - \mathbb{E}\{ |\zeta a x_1 + b| \} - b \mathbb{E}\{ |\zeta a x_1 + b| \}.
\]

Using App. C and the 1st moment of a Ricean RV,
\[
T_{22} = \frac{2 \mathbb{E}\{ |\zeta a x_1 + b| \}^2}{A^2}.
\]

Sub-Term 3: Using the first moment of a Ricean RV and noting that \( \mathbb{E}\{ d^H Q d \} = \eta_\delta^2 M \),
\[
T_{23} = \frac{\eta_\delta^2 \mathbb{E}\{ |\zeta a x_1 + b| \}^2}{2}.
\]

The result of \( \mathbb{E}\{ T_2 \} \) is,
\[
\mathbb{E}\{ T_2 \} = 2 \zeta_4 \frac{\beta_d^2}{\beta \rho \beta_d} \sqrt{\beta \rho \beta_d} \mathbb{E}\{ \hat{h}_d^H \hat{h}_a \} = 2 \mathbb{E}\{ |\zeta a x_1 + b| \} \frac{\mathbb{E}\{ |\zeta a x_1 + b| \}^2}{A^2}.
\]

The results for \( \mathbb{E}\{ T_3 \} \) and \( \mathbb{E}\{ T_4 \} \) are given in App. A and \( F_R \) is given by \( (7) \).

**Term 4:** Substituting \( \alpha \) from Sec. \( \text{II-B} \) into \( T_4 \),
\[
\mathbb{E}\{ T_4 \} = 4 \beta_d \beta_d \beta_d \mathbb{E}\{ Y^2 \} \mathbb{E}\{ a_b^H \hat{h}_a \}
\]
\[
= 4 \beta_d \beta_d \beta_d \mathbb{E}\{ Y^2 \} \mathbb{E}\{ a_b^H \hat{h}_a \}
\]
\[
= \left( \mathbb{P}^H R_a \mathbb{P} \right)^H \mathbb{P}^H R_a \mathbb{P}
\]

using the result for \( \mathbb{E}\{ Y^2 \} \) in App. A. Notice that \( \mathbb{E}\{ |a_b^H \hat{h}_a|^2 \} \) is the second moment of \( |a_b^H \hat{h}_a|^2 \). Using the

\[1\text{It is worth noting that App. C also gives the general solution for } \mathbb{E}\{ (ax + b) | (ax + b) \} \text{ where } x \sim \mathcal{N}(0, 1), a \in \mathbb{R} \text{ and } b \in \mathbb{C}.\]
result for $E \left\{ |a_0 H_1| \right\}$ in App. A and the moments of a Ricean RV [23 Eq. (2.3-58)],

$$
E \left\{ |a_0 H_1|^2 \right\} = \eta_0^2 |a_0|_H^2 + \zeta_0 \| B_1 a_0 \|_2^2.
$$

Therefore,

$$
E \{ T_4 \} = 4 \beta_4 \beta_{4n} (N + F_R)(\eta_0^2 |a_0 H_1|^2 + \zeta_0 A^2),
$$

(58) where $A$ is given in App. A and $F_R$ is given by (7).

**Term 5:** Substituting $\alpha$ from Sec. II-B into $T_5$,

$$
E \{ T_5 \} = 4 M \sqrt{\beta_4 \beta_{4n}} \eta_0^2 \frac{1}{4} \left\{a_0 H_1\right\}^2.
$$

(59) using the result for $E \left\{ |a_0^H H_1| \right\}$ in App. A. The variable $Y_3$ is a sum of products of the magnitudes of three correlated Ricean random variables. To the best of our knowledge the mean of such terms is intractable without the use of multiple infinite summations and special functions. As such we will use an approximation based on the gamma distribution to approximate $E \left\{ Y_3^3 \right\}$ (see App. D). Substituting this approximation, we have

$$
E \{ T_5 \} \approx 2 A M \zeta_0 \sqrt{\beta_4 \beta_{4n}} \eta_0^2 \frac{1}{4} \left\{a_0 H_1\right\}^2 L_1(\frac{-\kappa_d |a_0^H a_0|^2}{A^2}) C_1,
$$

with $C_1 = b^3 a \prod_{k=1}^3 (k + a)$ where $a$ and $b$ are defined in App. D.

**Term 6:** Substituting $\alpha$ from Sec. II-B into $T_6$,

$$
E \{ T_6 \} = (M \beta_{4n} \beta_{4n}) \eta_0^2 \left\{a_0 H_1\right\}^2
$$

Since $Y_4$ is even more complex than $Y_3$, we re-use the gamma approximation for $Y$ to make progress. Using the approximation for $E \left\{ Y_4 \right\}$ in App. D gives

$$
E \{ T_6 \} \approx (M \beta_{4n} \beta_{4n}) \eta_0^2 \left\{a_0 H_1\right\}^2 C_2,
$$

(60) with $C_2 = b^3 a \prod_{k=1}^3 (k + a)$ where $a$ and $b$ are defined in App. D.

**APPENDIX C**

$E \{ (ax + b) |ax + b| \}$ AND $I$

Here, we derive the expected value of $(ax + b) |ax + b|$ where $x \sim C N(0, 1)$, $a \in \mathbb{R}$ and $b \in \mathbb{C}$. Let $ax + b = \rho e^{j\theta}$ where $\rho$ and $\theta$ are the amplitude and phase of $ax + b$ respectively. Then, the joint PDF of the amplitude and phase is [20 Eq. (2.4)]

$$
f(\rho, \theta) = \frac{\rho}{\pi a^2} \exp \left\{-\frac{\rho^2}{a^2} - 2 \frac{b}{a^2} \rho \cos(\theta) - \frac{|b|^2}{a^2}\right\}.
$$

Using the joint PDF, the expectation $E \left\{ (ax + b) |ax + b| \right\}$ is,

$$
E \left\{ (ax + b) |ax + b| \right\} = \int_0^{\infty} \int_0^{\infty} \rho^2 e^{-\frac{\rho^2}{a^2}} \frac{e^{j\rho} e^{\frac{jb}{a^2} \rho \cos(\theta)}}{\pi a^2} d\rho d\theta.
$$

**APPENDIX E**

**CORRELATED RAYLEIGH EQUIVALENT OF $F_R$**

When $h_{nr}$ is a Rayleigh fading channel, we have $\kappa_{nu} = 0$, $\phi = 0$ and $I_0(0) = 1$. The integral form of $E \{ r_r r_k \}$ given by
Now noting that this term gives the mean of a Ricean random variable, we have
\[
\mathbb{E}\{r_i r_k\} = \frac{\sqrt{\pi} \zeta_{ru} \sqrt{1 - |\rho_{ik}|^2}}{2} \mathbb{E}\left\{ \eta_{ru} \overline{a}_{ru,i} + \zeta_{ru} \overline{h}_{sc,i} \right\} \\
\times L_{1/2} \left( -\frac{\eta_{ru} \overline{a}_{ru,k} + \zeta_{ru} |\rho_{ik}| \overline{h}_{sc,k}^2}{\zeta_{ru}^2 (1 - |\rho_{ik}|^2)} \right).
\]

Replacing the modified Bessel function of the first kind with its infinite series equivalent, we have
\[
\mathbb{E}\{r_i r_k\} = \sum_{m=0}^{\infty} \frac{(2m)!}{(m!)^2} \left( \int_0^\infty x^{m+1/2} e^{-x} \sqrt{x} dx \right)^2.
\]
Using Eq. (3.61.1) and Eq. (6.1.12), the integral in Eq. (63) is evaluated to be,
\[
\int_0^\infty x^{m+1/2} e^{-x} \sqrt{x} dx = \frac{(2m)!}{4} \pi^{1/2} (1 - |\rho_{ik}|^2)^{m+3/2},
\]
where \((1)_m\) is the Pochhammer symbol. Squaring and substituting into \(\mathbb{E}\{r_i r_k\}\), we get
\[
\mathbb{E}\{r_i r_k\} = \frac{\pi}{4} \left( 1 - |\rho_{ik}|^2 \right)^2 \sum_{m=0}^{\infty} \frac{(3/2)_m (3/2)_m |\rho_{ik}|^{2m}}{(m)!}.
\]
where \(a\) uses the fact that \((1)_m = m!\) and \(b\) replaces the infinite series with its hypergeometric equivalent. Taking the summation of \(\mathbb{E}\{r_i, r_k\}\) over all RIS elements \(N\), we get
\[
F = \sum_{i=1}^{N} \sum_{k=1}^{N} \frac{\pi}{4} \left( 1 - |\rho_{ik}|^2 \right)^2 \frac{3}{2} \left( \frac{3}{2} ; \frac{3}{2} ; 1 ; |\rho_{ik}|^2 \right),
\]
Which is identical to the correlated Rayleigh form of \(F_{ri}\) in Eq. (9).

**APPENDIX F**

**INTEGRAL FORM FOR \(\mathbb{E}\{r_i r_k\}\) WITH \(|\rho_{ik}| = 1\)**

For high correlation and K-factor values, the expectation of correlated Ricean random variables in Eq. (42) is computationally expensive to compute. In order to obtain an accurate result in such circumstances, the number of terms in the double summation becomes very large. Here, we propose the use of numerical integration to compute such expectations.

Let \(h_{sc} = \overline{R}_{tu}^{1/2} u_{tu}\) denote the normalized value of the scattered component of the UR-RIS channel in Sec. II-A.

Then,
\[
\mathbb{E}\{r_i r_k\} = \mathbb{E}\left\{ \eta_{ru} a_{ru,i} + \zeta_{ru} h_{sc,i} \right\} \mathbb{E}\left\{ \eta_{ru} a_{ru,k} + \zeta_{ru} h_{sc,k} \right\}.
\]
Now, let \(h_{sc,k} = \rho_{ik} h_{sc,i} + e \sqrt{1 - |\rho_{ik}|^2}\) where \(e \sim \mathcal{CN}(0, 1)\) and let \(\rho_{ik} = |\rho_{ik}| e^{i \phi}\), \(\overline{a}_{ru,i} = a_{ru,i} e^{i \phi}\), then
\[
\mathbb{E}\{r_i r_k\} = \mathbb{E}\left\{ \eta_{ru} \overline{a}_{ru,i} + \zeta_{ru} h_{sc,i} \right\} \times \mathbb{E}\left\{ \eta_{ru} \overline{a}_{ru,k} + \zeta_{ru} \left( \rho_{ik} h_{sc,i} + e \sqrt{1 - |\rho_{ik}|^2} \right) \right\},
\]
where \(h_{sc,i} \sim \mathcal{CN}(0, 1)\). Taking the expectation over \(e\) and noting that this term gives the mean of a Ricean random variable, we have
\[
\mathbb{E}\{r_i r_k\} = \frac{\sqrt{\pi} \zeta_{ru} \sqrt{1 - |\rho_{ik}|^2}}{2} \mathbb{E}\left\{ \eta_{ru} \overline{a}_{ru,i} + \zeta_{ru} h_{sc,i} \right\} \\
\times L_{1/2} \left( -\frac{\eta_{ru} \overline{a}_{ru,k} + \zeta_{ru} |\rho_{ik}| \overline{h}_{sc,k}^2}{\zeta_{ru}^2 (1 - |\rho_{ik}|^2)} \right).
\]

Finally, let \(a_i = \eta_{ru} \overline{a}_{ru,i} / \zeta_{ru} = a_{ri} + j a_{ji}, \ a_k = \eta_{ru} \overline{a}_{ru,k} / \zeta_{ru} = a_{rk} + j a_{jk}, \ b = |\rho_{ik}|^2 (1 - |\rho_{ik}|^2)\). Then we have,
\[
\mathbb{E}\{r_i r_j\} = \frac{\sqrt{\pi} \zeta_{ru} \sqrt{1 - |\rho_{ik}|^2}}{2} \mathbb{E}\left\{ (a_{ri} X + X^2) + (a_{ji} Y + Y^2) \right\} \\
\times L_{1/2} \left( -b((a_{rk} X + X^2) + (a_{jk} Y + Y^2)) \right) e^{(x^2 + y^2)} dy dx
\]
where \((a)\) involved transforming the integrals from cartesian to polar form, \(\theta_i = \angle a_{ru,i}\) and \(\theta_k = \angle a_{ru,k}\). Computing these integrals over \(1 \leq i, k \leq N\) for \(i \neq k\) yields Eq. (42). It is worth noting that the integral form of \(\mathbb{E}\{r_i r_k\}\) is computationally more efficient than the one presented in Eq. (42), where \(\mathbb{E}\{r_i r_k\}\) is given as an infinite summation of double integrals, both requiring integration over the region \([0, \infty)\).

For the benchmark case, correlation \(|\rho_{ik}| = 1\), both the double summation \(\mathbb{E}\{r_i r_k\}\) and integral form \(\mathbb{E}\{r_i r_k\}\) are invalid since substituting \(|\rho_{ik}| = 1\) results in an indeterminate answer. However, we can use the integral form and find its result as \(|\rho_{ik}| \to 1\). Firstly notice that correlation is only present in the term outside the integrals and also inside the Laguerre function. Let \(z = |a_k|^2 + r^2 + 2 r |a_k| \cos(\theta - \theta_k)\), then
\[
\lim_{|\rho_{ik}| \to 1} \sqrt{1 - |\rho_{ik}|^2} L_{1/2} \left( -\frac{|\rho_{ik}|^2}{1 - |\rho_{ik}|^2} z \right)
\]
\[
\lim_{|\rho_{ik}| \to 1} \sqrt{1 - |\rho_{ik}|^2} F_1 \left( \frac{1}{2} ; \frac{3}{2} ; 1 ; -\frac{|\rho_{ik}|^2}{1 - |\rho_{ik}|^2} z \right)
\]
\[
\lim_{|\rho_{ik}| \to 1} \sqrt{\frac{|\rho_{ik}|^2 z}{\Gamma(3/2)}} \left[ 1 + O \left( \frac{|\rho_{ik}|^2}{|\rho_{ik}|^2} \right) \right]
\]

where \((a)\) uses Eq. (13.6.9) to transform the Laguerre function into its confluent hypergeometric equivalent and \((b)\) uses Eq. (13.1.5) to replace the confluent hypergeometric function with its asymptotic equivalent. Substituting this limit
into the integral yields,
\[
E \{ r_i r_k \} = \frac{2}{\pi} \int_0^{\pi} \int_0^{\infty} e^{-r^2} \times \sqrt{|a_i|^2 + r^2 + 2r |a_i| \cos(\theta - \theta_i)}
\times \sqrt{|a_k|^2 + r^2 + 2r |a_k| \cos(\theta - \theta_k)} \, dr \, d\theta,
\]
where we make the substitution of \( a_k = a_i \) at \( |r_k| = 1 \). Computing these integrals over \( 1 \leq i, k \leq N \) for \( i \neq k \) yields (18).

REFERENCES
