Abstract

Let H be a graph. The generalized outerplanar Turán number of H , denoted by $f_{\mathcal{OP}}(n, H)$, is the maximum number of copies of H in an n -vertex outerplanar graph. Let P_k be the path on k vertices. In this paper we give an exact value of $f_{\mathcal{OP}}(n, P_4)$ and a best asymptotic value of $f_{\mathcal{OP}}(n, P_5)$. Moreover, we characterize all outerplanar graphs containing $f_{\mathcal{OP}}(n, P_4)$ copies of P_4 .

1 Introduction

In 1941, Turán [13] proved a classical result in the field of extremal graph theory. He determined exactly the maximum number of edges an n -vertex K_r -free graph may contain. After his result, for a graph H , the maximum number of edges in an n -vertex H -free graph, denoted by $\text{ex}(n, H)$, is named as *Turán number of H* . A major breakthrough in the study of the Turán number of graphs came in 1966, with the proof of the famous theorem by Erdős, Stone and Simonovits [6, 7]. They determined an asymptotic value of the Turán number of any non-bipartite graph H . In particular, they proved $\text{ex}(n, H) = \left(1 - \frac{1}{\chi(H)-1}\right) \binom{n}{2} + o(n^2)$, where $\chi(H)$ is the chromatic number of H .

Since then researchers have been interested working on Turán number of class of bipartite (degenerate) graphs and extremal graph problems with some more generality. Determining the maximum number of copies of H in an n -vertex F -free graph, denoted by $\text{ex}(n, H, F)$, is among such problems. Since we count the number of copies of a given graph which is not necessarily an edge, such an extremal graph problem is commonly named as *generalized Turán problem*. The results on $\text{ex}(n, K_r, K_t)$ by Zykov [14] (and independently by Erdős [5]), $\text{ex}(n, C_5, C_3)$ by Győri [10] and $\text{ex}(n, C_3, C_5)$ by Bollobás and Győri [9] were sporadic initial contributions.

Recently, some researchers were interested in extremal graph problems in some particular family of graphs, for instance, the family of planar graphs.

The study of generalized extremal problems in the family of planar graphs was initiated by Hakimi and Schmeichel [11] in 1979. Define the *generalized planar Turán number* of a graph H , denoted by $f_{\mathcal{P}}(n, H)$, as the maximum number of copies of H in an n -vertex planar graph. Hakimi and Schmeichel [11] determined the exact value of $f_{\mathcal{P}}(n, C_3)$ and $f_{\mathcal{P}}(n, C_4)$. Recently, this topic is active and many exact and best asymptotic values were obtained for different planar graphs. We refer [1, 4, 8] for more results.

Recently, Matolcsi and Nagy in [12] initiated the study of the generalized planar Turán number version in the family of outerplanar graphs.

Definition 1. *The generalized outerplanar Turán number of a graph H , denoted by $f_{\mathcal{OP}}(n, H)$, is the maximum number of copies of H in an n -vertex outerplanar graph. i.e.,*

$$f_{\mathcal{OP}}(n, H) = \max\{\mathcal{N}(H, G) : G \text{ is } n\text{-vertex outerplanar graph}\},$$

where $\mathcal{N}(H, G)$ is the number of copies of H as a subgraph in G .

Matolcsi and Nagy in [12] determined sharp and asymptotically sharp bounds of $f_{\mathcal{OP}}(n, H)$ for certain families of graphs H and described the extremal graphs. In particular, they determined the exponential growth of the generalized outerplanar Turán number of P_k , as a function of k . They also determined the exact value of $f_{\mathcal{OP}}(n, P_3)$ and characterized the extremal graphs.

Theorem 1. *(Matolcsi and Nagy [12])*

$$h(k) \binom{n}{2} < f_{\mathcal{OP}}(n, P_k) \leq 4^k \binom{n}{2}, \text{ where } \lim_{k \rightarrow \infty} \sqrt[k]{h(k)} = 4.$$

Theorem 2. *(Matolcsi and Nagy [12]) Suppose that $n \geq 3$. Then*

$$f_{\mathcal{OP}}(n, P_3) = \frac{n^2 + 3n - 12}{2},$$

and the unique extremal outerplanar graph containing $f_{\mathcal{OP}}(n, P_3)$ P_3 's as a subgraph is $K_1 + P_{n-1}$.

In this paper we determine the exact value of $f_{\mathcal{OP}}(n, P_4)$ and an asymptotic value $f_{\mathcal{OP}}(n, P_5)$. Moreover, we characterized all outerplanar graphs containing $f_{\mathcal{OP}}(n, P_4)$ copies of P_4 as a subgraph. The following two theorems summarize our results.

Theorem 3. *For $n \geq 8$,*

$$f_{\mathcal{OP}}(n, P_4) = 2n^2 - 7n + 2.$$

Moreover, for $n \geq 9$, the only n -vertex outerplanar graph containing $f_{\mathcal{OP}}(n, P_4)$ number of P_4 is $K_1 + P_{n-1}$.

Theorem 4.

$$f_{\mathcal{OP}}(n, P_5) = \frac{17}{4}n^2 + \Theta(n).$$

Let G be a graph. The vertex and edge sets of G are denoted respectively by $V(G)$ and $E(G)$. For a vertex $v \in V(G)$, the degree of v is denoted by $d_G(v)$. We will use the notation $d(v)$ instead of $d_G(v)$ if there is no ambiguity. The maximum and minimum degree of G are denoted by $\Delta(G)$ and $\delta(G)$ respectively. We denote a k -vertex path with vertices v_1, v_2, \dots, v_k in sequential order by (v_1, v_2, \dots, v_k) . We may call a k -vertex path as a path of length $k - 1$, or simply a $(k - 1)$ -path. We use the notation $[k]$ to describe the set of the first k positive integers.

We state the following two easy lemmas without proof.

Lemma 1. *Every maximal outerplanar graph contains a degree 2 vertex.*

Lemma 2. *For an n -vertex maximal outerplanar graph G , $e(G) = 2n - 3$.*

2 Generalized outerplanar Turán number of the P_4

Figure 1: An n -vertex maximal outerplanar graph $G_n = K_1 + P_{n-1}$.

proof of Theorem 3. It is easy to check that an n -vertex maximal outerplanar graph $G_n = K_1 + P_{n-1}$ shown in Figure 1 contains $2n^2 - 7n + 2$ P_4 's. Therefore,

$$f_{\mathcal{OP}}(n, P_4) \geq 2n^2 - 7n + 2.$$

Next we will show $f_{\mathcal{OP}}(n, P_4) \leq 2n^2 - 7n + 2$. Let G be an n -vertex maximal outerplanar graph. We proof the upper bound of $f_{\mathcal{OP}}(n, P_4)$ by induction on the number of vertices in G . First, we check the base case that when $n = 7$.

Since each outerplanar graph contains a degree 2 vertex, now we will show that there exists a degree 2 vertex in G , say w , such that the number of P_4 's containing w is at most $4n - 9$ and consequently by deleting w and the induction hypothesis we get

$$\mathcal{N}(P_4, G) \leq 2(n-1)^2 - 7(n-1) + 2 + (4n-9) = 2n^2 - 7n + 2.$$

Which implies that $f_{\mathcal{OP}}(n, P_4) \leq 2n^2 - 7n + 2$.

Let G be an n -vertex ($n \geq 8$) maximal outerplanar graph and x be a degree 2 vertex in G . Since each face (except the unbounded face) in G is a triangle, there exist u and v such that u , v and x forms a triangle. Let $d(u) = a + 2$ and u_1, u_2, \dots, u_a be the vertices which are adjacent to u (except v and x) in counterclockwise direction. Let $d(v) = b + 2$ and v_1, v_2, \dots, v_b be vertices adjacent to v (except u and x) in clockwise direction. Since every face of G (except the unbounded face) is a triangle. Thus, necessarily the vertices u_a and v_b are identical, see Figure 2. For the reason that G is a maximal outerplanar graph, $\{u_i, u_{i+1}\} \in E(G)$ and $\{v_j, v_{j+1}\} \in E(G)$, where $i \in [a-1]$ and $j \in [b-1]$, see the red edges in Figure 2.

Notice that for $i \in [a-1]$ and $j \in [b-1]$, the arc joining u_i and u_{i+1} in counterclockwise direction and the arc joining v_j and v_{j+1} in clockwise direction may contain an interior vertex. We labeling such vertices. For each $i \in [a-1]$, denote the interior vertices (if any) between the vertices u_i and u_{i+1} in counterclockwise direction by $u_i^1, u_i^2, \dots, u_i^{n_i}$. Similarly for each $j \in [b-1]$, denote the interior vertices (if any) between v_j and v_{j+1} in clockwise direction by $v_j^1, v_j^2, \dots, v_j^{n_j}$.

It can be seen that the 3-paths that contain the vertex x are those starting with (x, u, u_i, \dots) , (x, u, v, \dots) , (v, x, u, \dots) , (x, v, v_i, \dots) , (x, v, u, \dots) and (u, x, v, \dots) . In all the cases, the vertex x is either an end vertex of the 3-path or an end vertex of the middle edge of a 3-paths.

The distance between a vertex v and an edge $e = \{u, w\}$ is defined as $d(v, e) = \min\{d(v, u), d(v, w)\}$. Let P be a 3-path containing the vertex x . We define a "red edge" of P with respect to x as the farthest edge in P from x . It can be seen that there are two possibilities based on the position of x in P , see Figure 3.

Next we count the number of 3-paths containing x in G considering the number of possibilities that an edge in G can be red edge. The following gives us the counting lists for each edge.

1. The edges $\{x, u\}$, $\{x, v\}$ and $\{u, v\}$ can not be a red edge in a 3-path that contains x .
2. Each edge $\{u, u_i\}$, $i \in [a-1]$, is a red edge in two 3-paths containing the vertex x . Indeed, (v, x, u, u_i) and (x, v, u, u_i) are the 3-paths. Similarly each edge $\{v, v_j\}$, $j \in [b-1]$, is a red edge in two 3-paths containing the vertex x .
3. Each edge $\{u_i, u_{i+1}\}$, $i \in [a-2]$, is a red edge in two 3-paths containing the vertex x . Indeed, (x, u, u_i, u_{i+1}) and (x, u, u_{i+1}, u_i) are the 3-paths. Similarly, each edge $\{v_j, v_{j+1}\}$, $j \in [b-2]$, is a red edge in two 3-paths containing the vertex x .

Figure 2: Structure of a maximal outerplanar graph

Figure 3: Red edges of a 3-path P with respect to a vertex x .

4. The edge $\{u, u_a\}$ is a red edge in three 3-paths containing the vertex x . Indeed, the 3-paths are (v, x, u, u_a) , (x, v, u_a, u) and (x, v, u, u_a) . Similarly, the edge $\{v, v_b\}$ is a red edge in three 3-paths containing the vertex x .
5. The edge $\{u_a, u_{a-1}\}$ is a red edge in three 3-paths containing the vertex x . Here it can be checked that the paths are (x, u, u_a, u_{a-1}) , (x, u, u_{a-1}, u_a) and (x, v, u_a, u_{a-1}) . Similarly, the edge $\{v_b, v_{a-1}\}$ is a red edge in three 3-paths containing the vertex x .
6. For $i \in [a - 2]$, if there exist interior vertices between u_i and u_{i+1} in counterclockwise direction, then each edge $\{u_i^k, u_i^{k+1}\}$, $k \in [n_i - 1]$ is not contained in a 3-path that contains x . Moreover, for each vertex u_i^* in $\{u_i^1, u_i^2, \dots, u_i^{n_i}\}$ which is adjacent to u_i or u_{i+1} , the edge $\{u_i, u_i^*\}$ or $\{u_i^*, u_{i+1}\}$ is a red edge in exactly one 3-path that contains x .
7. For $j \in [b - 2]$, if there exist interior vertices between v_j and v_{j+1} in clockwise direction, then each edge $\{v_j^k, v_j^{k+1}\}$, $k \in [n_j - 1]$ is not contained in a 3-path that contains x . Moreover, for each vertex v_j^* in $\{v_j^1, v_j^2, \dots, v_j^{n_j}\}$ which is adjacent to v_j or v_{j+1} , the edge $\{v_j, v_j^*\}$ or $\{v_j^*, v_{j+1}\}$ is a red edge in one 3-path that contains x .

8. If there exist interior vertices between u_{a-1} and u_a in counterclockwise direction, then each edge $\{u_a^k, u_a^{k+1}\}$, $k \in [n_a - 1]$ is not contained in 3-path that contains x . Moreover for each vertex $u_a^* \in \{1, 2, \dots, n_a\}$ which is adjacent to u_{a-1} , the edge $\{u_a, u_a^*\}$ is a red edge in one 3-path that contains x . On the other hand, for each vertex $u_a^* \in \{u_a^1, u_a^2, \dots, u_a^{n_a}\}$ which is adjacent to u_a , the edge $\{u_a, u_a^*\}$ is a red edge in two 3-paths that contains x . Indeed that paths are (x, u, u_a, u_a^*) and (x, u_a, u_a^*) .
9. If there exist interior vertices between v_{b-1} and v_b in counterclockwise direction, then each edge $\{v_b^k, v_b^{k+1}\}$, $k \in [n_b - 1]$ is not contained in 3-path that contains x . Moreover for each vertex $v_b^* \in \{1, 2, \dots, n_b\}$ which is adjacent to v_{b-1} , the edge $\{v_b, v_b^*\}$ is a red edge in one 3-path that contains x . On the other hand, for each vertex $v_b^* \in \{v_b^1, v_b^2, \dots, v_b^{n_b}\}$ which is adjacent to v_b , the edge $\{v_b, v_b^*\}$ is a red edge in two 3-paths that contains x . Indeed that paths are (x, v, v_b, v_b^*) and (x, v_b, v_b^*) .

Notice that the number of edges in an n -vertex maximal outerplanar graph is $2n - 3$.

We need the following claims to complete the proof of Theorem 3.

Claim 1. *For each $i \in [a - 2]$ and $j \in [b - 2]$ there is no interior vertices between u_i and u_{i+1} in counterclockwise direction, and no interior vertices between v_j and v_{j+1} in clockwise direction. Otherwise the number of 3-paths containing x is at most $4n - 10$.*

Proof. Without loss of generality, assume that there exist interior vertices between u_i and u_{i+1} in counterclockwise direction, for some $i \in [a - 2]$. We separate the proof into two cases.

- i. There exist at least two interior vertices between u_i and u_{i+1} in counterclockwise direction. Then the edge $\{u_i^1, u_i^2\}$ is not contained in any 3-path containing x . Thus, the number of 3-paths containing x is at most $2((2n - 3) - 8) + 12 = 4n - 10$.
- ii. There exists one interior vertices between u_i and u_{i+1} in counterclockwise direction. Then the edge $\{u_i, u_i^1\}$ and $\{u_{i+1}, u_i^1\}$ are contained in only one 3-path each. Indeed, (x, u, u_i, u_i^1) and (x, u, u_{i+1}, u_i^1) , respectively. Thus in this case the number of 3-paths containing the vertex x is at most $2((2n - 3) - 9) + 14 = 4n - 10$.

This completes the proof of Claim 1. □

Claim 2. *There is no interior vertices between u_{a-1} and u_a . Moreover there is no interior vertices between v_{b-1} and v_b . Otherwise, there exists a degree 2 vertex in G such that the number of 3-paths containing this vertex is at most $4n - 10$.*

Proof. Without loss of generality, we assume that there exist interior vertices between u_{a-1} and u_a in counterclockwise direction. We distinguish two cases considering the number of interior vertices.

- i. The number of interior vertices between u_{a-1} and u_a in counterclockwise direction is at least 2. In this case the edge $\{u_{a-1}^1, u_{a-1}^2\}$ is contained in no 3-path containing x . Thus the number of 3-paths containing x in G is at most $2((2n - 3) - 8) + 12 = 4n - 10$.

ii. The number of interior vertices between u_{a-1} and u_a in clockwise direction is only one.

It can be shown that u_{a-1}^1 is a degree 2 vertex such that the number of 3-paths containing u_{a-1}^1 is at most $4n - 10$. Indeed, we interchange the roles of x with u_{a-1}^1 , u with u_a and v with u_{a-1} .

Since $n \geq 8$, either there exist one interior vertex between u and u_{a-1} in counterclockwise direction and one between v and u_a in clockwise direction or there exist at least two interior vertices between u and u_{a-1} in counterclockwise direction or between v and u_a in clockwise direction. We separate the rest proof into 2 subcases correspondingly.

- (a) There exist one interior vertex u_1 between u and u_{a-1} in counterclockwise direction and v_1 between v and $u_a = v_b$ in clockwise direction, see Figure 4. It can be checked that in this case $n = 8$ and the number of 3-paths in G is 74 which is equal to $2n^2 - 7n + 2$.

Figure 4: An 8-vertex maximal outerplanar graphs

- (b) There exist at least two interior vertices between u and u_{a-1} in counterclockwise direction or between v and u_a in clockwise direction. Without loss of generality, we assume that there exist at least two interior vertices between u and u_{a-1} in counterclockwise direction. Hence all the interior vertices between u and u_{a-2} (counterclockwise direction) are not adjacent to the vertex u_{a-1} . Otherwise, it contracts to the face that G is outerplanar. It can be seen that the edges $\{u_{a-2}, u_{a-3}\}$ and vx are red edges in only one 3-path containing u_{a-1}^1 . Indeed the 3-paths are $(u_{a-1}^1, u_{a-1}, u_{a-2}, u_{a-3})$ and (u_{a-1}^1, u_a, v, x) respectively. In fact the vertex u_{a-3} is nothing but u_1 if the number of interior vertices between u and u_{a-1} (counterclockwise direction) is two. Notice that the edges $\{u, u_{a-2}\}$, $\{u, u_{a-1}\}$, $\{u, u_a\}$ and $\{u, v\}$ are red edges in three 3-paths containing the vertex u_{a-1}^1 . Therefore the number of 3-paths containing u_{a-1}^1 is at most $2((2n - 3) - 9) + 14 = 4n - 10$.

This completes the proof of Claim 2. □

Claim 3. For each $i \in [a - 1]$ and $j \in [b - 1]$, if there is no interior vertex between u_i and u_{i+1} and no interior vertex between v_j and v_{j+1} . Then either $\mathcal{N}(P_4, G) = 2n^2 - 7n + 2$ or

there exists a degree 2 vertex, say z , such that the number of 3-paths containing z is at most $4n - 10$.

Proof. Notice that both a and b are at least 1. We distinguish two cases to finish the proof of the claim.

1. Either $a = 1$ or $b = 1$. Without loss of generality assume that $b = 1$. In this case $u_a = v_1$ and by Claim 1 u is adjacent to every vertices in G and we exactly get the maximal outerplanar graph shown in Figure 1 and hence $\mathcal{N}(P_4, G) = 2n^2 - 7n + 2$.
2. $a, b \geq 2$. Now consider the degree 2 vertex u_1 and the two adjacent vertices u_2 and u . Next we interchange the roles of x with u_1 , u with u_2 and v with u and check what happens to our previous computation with this choice of degree 2 vertex u_1 . Since v is adjacent to u_a , u can not be adjacent with any interior vertices between v and u_a in clockwise direction. Clearly the vertex v_1 is an interior vertex between v and u_a in clockwise direction. Thus by Claim 1, the number of 3-paths containing the vertex u_1 is at most $4n - 10$.

This completes the proof of Claim 3. □

Considering Claims 1, 2 and 3, the only case that G contains $2n^2 - 7n + 2$ number of 3-paths is when $a = 1$ and v is adjacent to every vertex of G or $b = 1$ and u is adjacent to every vertex of G . Otherwise, there exists a vertex of degree 2, say v , such that the number of 3-paths containing v is at most $4n - 10$. Hence by deleting v and the induction hypothesis we get

$$\begin{aligned} \mathcal{N}(P_4, G) &\leq \mathcal{N}(P_4, G - v) + 4n - 10 \leq 2(n - 1)^2 - 7(n - 1) + 2 + (4n - 10) = 2n^2 - 7n + 1 \\ &< 2n^2 - 7n + 2. \end{aligned}$$

Notice that in both cases when G contains $2n^2 - 7n + 2$, the graph we get is isomorphic to $K_1 + P_{n-1}$ which is shown in Figure 1.

To complete proof of the theorem we need to start of the induction step when $n = 7$.

Claim 4. $f_{\mathcal{OP}}(7, P_4) = 51 = 2n^2 - 7n + 2$.

Proof. Let G be a 7-vertex maximal outerplanar graph. It can be checked that there are only

Figure 5: All 7-vertex maximal outerplanar graphs

4, 7-vertex maximal outerplanar graphs, see the lists with their number of 3-paths. There are 2 graphs attaining the upper bound. This completes the proof of Claim 4. \square

This completes the proof of Theorem 3. \square

3 Generalized outerplanar Turán number of the P_5

proof of Theorem 4. The following construction verifies the lower bound.

Definition 2. Let n be an even positive integer and $C_n = (v_1, v_2, \dots, v_n)$ be an n -vertex cycle. An n -vertex maximal outerplanar graph G_n (see Figure 6) is defined as follows:

Figure 6: An n -vertex maximal outerplanar graph G_n .

1. C_n is the outer cycle of G_n ,
2. $E(G_n) = E(C_n) \cup \{\{v_1, v_i\} : i \in \{\frac{n}{2}, \frac{n}{2} + 1, \dots, n\}\} \cup \{\{v_1, v_i\} : i \in \{3, 5, \dots, \frac{n}{2} - 2\}\} \cup \{\{v_i, v_{i+2}\} : i \in \{3, 5, \dots, \frac{n}{2} - 2\}\}$.

Lemma 3. $\mathcal{N}(P_5, G_n) \approx \frac{17}{4}n^2$.*

Proof. It is easy to see that P_5 's of the form $(u_1, u_2, u_3, u_4, u_5)$, where $u_i \in V(G_n)$ ($i \in [5]$) and $u_j \neq v_1$ (for all $j \in \{2, 3, 4\}$) is constant and hence the number of such P_5 's in G is linear.

Next we count the number of P_5 's containing v_1 as an interior vertex. We call such a P_5 as a *symmetric* P_5 if v_1 is a middle vertex (see Figure 7, left), otherwise we call the P_5 as *asymmetric* P_5 (see Figure 7, right). Denote the two vertices adjacent to v_1 in the symmetric P_5 as x_1 and x_2 . Moreover, denote the asymmetric P_5 as $(x_1, v_1, x_2, x_3, x_4)$.

Figure 7: Structure of P_5 's containing v_1 as an interior vertex.

Denote $S_1 = \{v_2, v_3, \dots, v_{\frac{n}{2}-1}\}$, $S_2 = \{v_{\frac{n}{2}+1}, v_{\frac{n}{2}+2}, \dots, v_{n-1}\}$. Next we count the number of symmetric and asymmetric P_5 's containing v_1 as an interior vertex considering the positions of x_1 and x_2 .

1. Both x_1 and x_2 are in S_1 .

- Symmetric P_5 's. Since degree of x_1 and x_2 are 5, the number of such P_5 's is roughly $4 \times 4 \times \binom{\frac{n}{2}}{2} = \frac{n^2}{2}$.
- Asymmetric P_5 's. It can be checked that the number of 2-paths of the form (x_2, x_3, x_4) is 8. Since we have two options of doing that, number of such P_5 's is roughly $2 \times 8 \times \binom{\frac{n}{2}}{2} = \frac{n^2}{2}$.

2. Both x_1 and x_2 are in S_2 .

- Symmetric P_5 's. Since degree of x_1 and x_2 is 3, the number of such P_5 's is roughly $2 \times 2 \times \binom{\frac{n}{2}}{2} = \frac{n^2}{2}$.
- Asymmetric P_5 's. Clearly the number of 2-paths of the form (x_2, x_3, x_4) is 2. Since we have two options of doing that, the number of such P_5 's is roughly $2 \times 2 \times \binom{\frac{n}{2}}{2} = \frac{n^2}{2}$.

3. x_1 in S_1 and x_2 in S_2 or vice versa.

- Symmetric P_5 's. Without loss of generality assume $x_1 \in S_1$ and $x_2 \in S_2$. Hence degree of x_1 and x_2 are respectively 3 and 5. Thus the symmetric P_5 's is roughly $2 \times 4 \times \frac{n}{2} \times \frac{n}{4} = n^2$.

* $f(n) \approx g(n) \Leftrightarrow \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 1$.

- Asymmetric P_5 's. For the case x_2 is in S_1 , the number of 2-paths of the form (x_2, x_3, x_4) is 8. Thus the number of such asymmetric P_5 's is roughly $8 \times \frac{n}{2} \times \frac{n}{4} = n^2$. On the other hand for the case that x_2 is in S_2 , the number of such asymmetric P_5 's is $2 \times \frac{n}{2} \times \frac{n}{4} = \frac{n^2}{4}$.

Therefore, $\mathcal{N}(P_5, G_n) \approx \frac{17}{4}n^2$. This completes proof of Lemma 3. \square

The following lemma claims, no matter how the $\frac{n}{4}$ degree 2 vertices are distributed in the outer cycle C_n , the maximal outerplanar graph contains roughly $\frac{17}{4}n^2$ P_5 's.

Lemma 4. *Let n be even and G be an n -vertex maximal outerplanar with outer cycle C_n and let G contains $\frac{n}{4}$ degree 2 vertices and all the remaining vertices are adjacent to a vertex, say $v \in V(C_n)$. Then $\mathcal{N}(P_5, G) \approx \frac{17}{4}n^2$.*

Proof. Denote vertices which are adjacent to v in counterclockwise direction as v_1, v_2, \dots, v_r . Obviously $r = \frac{3n}{4} + 3$. Denote a degree 2 vertex (if exist) between v_i and v_{i+1} in the counterclockwise direction by v_i^1 . Notice that in such case $\{v_i, v_{i+1}\} \in E(G)$.

Next we count the number of P_5 's containing v (but not as a terminal vertex). Precisely speaking we count the number of symmetric and asymmetric P_5 's shown in Figure 8.

Figure 8: P_5 's containing v as an interior vertex.

- Asymmetric P_5 's. Here we count in how many ways each edge, which is different from $\{v, v_i\}$ $i \in [k]$, is contained in an asymmetric P_5 as terminal edge (the red edge which is shown in Figure 8, right).

For an edge $\{v_i, v_{i+1}\}$, it can be checked that it is contained in two possibilities for each other vertex $v_j \notin \{v_{i-1}, v_i, v_{i+1}, v_{i+2}\}$. Indeed, $(v_j, v, v_{i-1}, v_i, v_{i+1})$ and $(v_j, v, v_{i+2}, v_{i+1}, v_i)$. The number of such edges is roughly $2n - \frac{3n}{4} - 2 \times \frac{n}{4} = \frac{3n}{4}$. This implies, the number of P_5 's containing the edges $\{v_i, v_{i+1}\}$ as terminal edge is $\frac{3n}{4} \times 2 \times \frac{3n}{4} = \frac{9n^2}{8}$.

Let v_i^1 be a degree 2 vertex between v_i and v_{i+1} . Now we count in how many ways the edge $\{v_i, v_i^1\}$ is possibly contained in an asymmetric P_5 as a terminal edge. In this case for each $v_j \notin \{v_{i-1}, v_i, v_{i+1}\}$, it can be checked that the edge $\{v_i, v_i^1\}$ is contained in three such P_5 's. Indeed, the paths are $(v_j, v, v_{i-1}, v_i, v_i^1)$, $(v_j, v, v_{i+1}, v_i^1, v_i)$ and $(v_j, v, v_{i+1}, v_i, v_i^1)$. Notice that the same property hold for the edge $\{v_i^1, v_{i+1}\}$. Clearly the number of such edges is $2 \times \frac{n}{4}$. Therefore, the number of P_5 's containing the edge $\{v_j, u\}$, where u is a degree two vertex, as a terminal edge is $\frac{3n}{4} \times 3 \times \frac{n}{2} = \frac{9n^2}{8}$.

- Symmetric P_5 's. Here P_5 is of the form shown in Figure 8(left). In counting such P_5 's we consider three possibilities considering the two terminal red edges. Let the red edges are of the form $\{v_i, v_{i+1}\}$ and $\{v_j, v_{j+1}\}$. In this case we have there are four P_5 's of such a form. Indeed the paths are $(v_{i+1}, v_i, v, v_{j+1}, v_j)$, $(v_{i+1}, v_i, v, v_j, v_{j+1})$, $(v_i, v_{i+1}, v, v_{j+1}, v_j)$ and $(v_i, v_{i+1}, v, v_j, v_{j+1})$. Notice that we have roughly $\binom{\frac{3n}{2}}{2}$ such pairs of edges. Therefore the number of symmetric P_5 's such that the terminal red edges are both in $\{v_i, v_{i+1}\}$ is roughly $4 \times \binom{\frac{3n}{2}}{2} \approx \frac{9n^2}{8}$.

It is easy to check that number of symmetric P_5 such that both terminal red edges are in $\{u, v_i\}$, where u is a degree two vertex, is only one. Roughly such pair of edges is $\binom{\frac{n}{2}}{2} \approx \frac{n^2}{8}$.

Finally we count the the number of symmetric P_5 's such that one terminal red edge is of the form $\{v_i, v_{i+1}\}$ and the other terminal red edge is of the form $\{v_j, v_j^1\}$. Here it can be checked that the number of such P_5 's is two, namely, $(v_i, v_{i+1}, v, v_j, v_j^1)$ and $(v_{i+1}, v_i, v, v_j, v_j^1)$. Clearly the number of such pair of edges is roughly $\frac{3n}{3} \times \frac{n}{2} = \frac{3n^2}{8}$. Thus, the number of P_5 's of such kind is roughly $2 \times \frac{3n^2}{8} = \frac{6n^2}{8}$.

Therefor, adding all the symmetric and asymmetric P_5 's we have,

$$\mathcal{N}(P_5, G) \approx \frac{9n^2}{8} + \frac{9n^2}{8} + \frac{9n^2}{8} + \frac{n^2}{8} + \frac{6n^2}{8} = \frac{17}{4}n^2.$$

This completes proof of Lemma 4. □

We need the following lemmas to complete the proof of Theorem 4.

Lemma 5. *Let T be an n -vertex tree with $\Delta(T) \leq 3$. Then there is an edge $e \in E(T)$ such that both components of $T - e$ have at least $\frac{n-1}{3}$ vertices.*

Proof. For an obvious reason, we assume that $\Delta(T) \geq 2$. Let k be the number of degree 3 vertices in T . Clearly the lemma holds when $k = 0$. Indeed, if $k = 0$, then T is a path. We can take an edge e which is incident to a center vertex of T so that both components of $T - e$ have at least $\frac{n-1}{2} > \frac{n-1}{3}$ vertices.

Next we apply induction on the number of degree 3 vertices in T . Let $k \geq 1$, v be a degree 3 vertex in T and $N(v) = \{v_1, v_2, v_3\}$. For $i \in [3]$, denote the maximal sub-tree of T containing the vertex v_i but not v by T_i . Let $v(T_i) = n_i$, $i \in [3]$. Clearly either n_1 or n_2 or n_3 is at least $\frac{n-1}{3}$. Otherwise, $v(T) - 1 = \sum_{i=1}^3 n_i < 3 \left(\frac{n-1}{3}\right) = n - 1$, which is a contradiction.

Without loss of generality assume that $n_1 \geq \frac{n-1}{3}$. If $n_2 + n_3 \geq \frac{n-1}{3}$, we are done with the choice of $e = \{v, v_1\}$.

Let $n_2 + n_3 < \frac{n-1}{3}$. Consider the tree T' which is obtained from T by deleting the vertices in T_2 and T_3 and identifying the vertex v and a terminal vertex (say r_1) of an $(n_2 + n_3 + 1)$ -vertex path $(r_1, r_2, \dots, r_{n_2+n_3+1})$. Obviously, $v(T') = n$ and the number of degree-3 vertices in T' is less than k . So by induction, there is an edge $e \in E(T')$ such that both components $T' - e$ has at least $\frac{n-1}{3}$ vertices. For clear reason e can not be an edge of

the path $(v_1, v, r_2, \dots, r_{n_2+n_3+1})$. In other words, $e \in E(T_1)$. Therefore with this choice of edge, both components of $T - e$ has at least $\frac{n-1}{3}$ vertices.

This completes the proof of Lemma 5 □

Definition 3. Let G be a maximal outerplanar graph and C be its outer cycle. An edge $\{x, y\} \in E(G)$ is called a chord if x and y are two nonconsecutive vertices of C .

Lemma 6. Let G be an n -vertex maximal outerplanar graph. Then there is a chord $\{x, y\}$ in G such that the number of interior vertices between x and y in counterclockwise and clockwise directions are greater than $\frac{n}{3}$.

Proof. Let the outer cycle of G be C . Each edge in $E(G) \setminus E(C)$ are contained in two triangular face. Let T be the dual of G minus the vertex representing the unbounded face. Clearly T is a tree, with $\Delta(T) \leq 3$. Since G contains $n - 2$ triangles, $v(T) = n - 2$.

By Lemma 5, there is an edge $e \in E(T)$ such that $T - e$ results components with at least $\frac{n-3}{3}$ vertices. Let the end vertices of e be x and y and e' be an edge in G which is shared by the triangular faces represented by x and y respectively in the dual of G . Thus the number of vertices between the end vertices of e' in counterclockwise and clockwise directions are at least $\frac{n-3}{3} + 2 > \frac{n}{3}$. This completes the proof of Lemma 6. □

Definition 4. Let G be a maximal outerplanar graph. A chord $\{x, y\}$ in G is called a “nice chord” if the number of vertices between x and y (including x and y) in counterclockwise and clockwise direction are at least $\frac{n}{3}$.

Definition 5. Let G be a maximal outerplanar graph and $\{x, y\}$ be a chord in G . Let I_1 be a set of interior vertices between x and y in counterclockwise direction and I_2 be the set of interior vertices between x and y in clockwise direction. A path P of length four in G is called a crossing P_5 with respect to $\{x, y\}$ if P contains a vertex in both I_1 and I_2 .

Notice that every crossing P_5 with respect to the chord $\{x, y\}$ contains either x or y . We classify the crossing P_5 's with respect to $\{x, y\}$ as follows.

- i. A crossing P_5 with respect to $\{x, y\}$ is called **Type-I crossing P_5** if it contains the edge $\{x, y\}$. Notice that, the edge $\{x, y\}$ can not be a terminal edge of a crossing P_5 . Moreover, such a crossing P_5 contains only one vertex in I_1 and two vertices in I_2 or vice-versa. See Figure 9.

Figure 9: An example of Type-I crossing P_5 with respect to $\{x, y\}$.

ii. A crossing P_5 with respect to $\{x, y\}$ is called **Type-II crossing P_5** if it contains both x and y , but not the edge $\{x, y\}$. Notice that both x and y can not be terminal vertices of the P_5 . In this case we have two possibilities based on the position of x and y .

- If both x and y are not terminal vertex of the P_5 , then we call the crossing P_5 as **Type-II(A) crossing P_5** , see Figure 10 (the first two graphs).

Figure 10: Examples of Type-II crossing P_5 with respect to $\{x, y\}$.

- If either x or y is a terminal vertex of the P_5 , then we call the P_5 as **Type-II(B) crossing P_5** , see Figure 10 (last two graphs).

iii. A crossing P_5 with respect to $\{x, y\}$ is called **Type-III crossing P_5** if the crossing P_5 contains either x or y but not both.

- If the crossing P_5 contains two vertices in I_1 and two vertices of I_2 , then we call the P_5 as **Type-III(A) crossing P_5** , see Figure 11(left).
- If the crossing P_5 contains only one vertex in I_1 or I_2 , then we call the P_5 as **Type-III(B) crossing P_5** , see Figure 11(right).

Figure 11: Examples of Type-III crossing P_5 with respect to $\{x, y\}$.

Definition 6. Let G be a maximal outerplanar graph and e be a chord in G . Denote the number of crossing P_5 's with respect to e by $\mathcal{N}_e(P_5, G)$.

Lemma 7. Let G be an n -vertex maximal outerplanar graph and $e = \{x, y\}$ be a nice chord in G . Let n_1 be the number of interior vertices laying between x and y in counterclockwise

direction and n_2 be the number of interior vertices between x and y in clockwise direction. Then

$$\mathcal{N}_e(P_5, G) = \frac{17}{2}n_1n_2 + O(n).$$

Proof. Let C be the outer cycle of G and I_1 and I_2 be the set of interior vertices between x and y in counterclockwise and clockwise direction respectively. Let x be adjacent with s_1 vertices in I_1 and the vertices in counterclockwise direction be $lx_1, lx_2, \dots, lx_{s_1}$. Let y be adjacent with t_1 vertices in I_1 and the vertices in clockwise direction be $ly_1, ly_2, \dots, ly_{t_1}$. Obviously ly_{t_1} and lx_{s_1} are identical vertices. Similarly let x and y be adjacent with p_1 and q_1 number of vertices in I_2 respectively. Let the vertices which are adjacent to x in clockwise direction and adjacent to y in counterclockwise direction respectively be $rx_1, rx_2, \dots, rx_{p_1}$ and $ry_1, ry_2, \dots, ry_{q_1}$. Obviously, rx_{p_1} and ry_{q_1} are identical vertices. The remaining vertices of G are labeled as follows.

- Label the interior vertices in clockwise direction (if any) between rx_i and rx_{i+1} by $rx_i^1, rx_i^2, \dots, rx_i^{n_i}$, $i \in [p_1 - 1]$.
- Label the interior vertices between ry_j and ry_{j+1} in counterclockwise direction (if any) by $ry_j^1, ry_j^2, \dots, ry_j^{n_j}$, $j \in [q_1 - 1]$.
- Label the interior vertices in counterclockwise direction (if any) between lx_k and lx_{k+1} by $lx_k^1, lx_k^2, \dots, lx_k^{n_k}$, $k \in [s_1 - 1]$.
- Label the interior vertices in clockwise direction (if any) between ly_ℓ and $ly_{\ell+1}$ by $ly_\ell^1, ly_\ell^2, \dots, ly_\ell^{n_\ell}$, $\ell \in [t_1 - 1]$.

Since each face (except the unbounded face) of G are triangular, for each $i \in [p_1 - 1]$, $j \in [q_1 - 1]$, $k \in [s_1 - 1]$ and $\ell \in [t_1 - 1]$, the edges $\{rx_i, rx_{i+1}\}$, $\{ry_j, ry_{j+1}\}$, $\{lx_k, lx_{k+1}\}$ and $\{ly_\ell, ly_{\ell+1}\}$ are in G . The following claim is important to finish proof of the lemma.

Claim 5. *If a maximal outerplanar graph H has the property that either there is no or only one interior vertex between each pair (lx_k, lx_{k+1}) counterclockwise direction, $(ly_\ell, ly_{\ell+1})$ clockwise direction, (rx_i, rx_{i+1}) clockwise direction and (ry_j, ry_{j+1}) counterclockwise direction, where $i \in [p_1 - 1]$, $j \in [q_1 - 1]$, $k \in [s_1 - 1]$ and $\ell \in [t_1 - 1]$, then*

$$\mathcal{N}_e(P_5, H) = \frac{17}{2}n_1n_2 + O(n).$$

Proof. Let the set of interior vertices between x and lx_{s_1} in counter clockwise direction be S . Denote the size of S with s and the number of degree 2 vertices in S by s_0 . Denote the set of vertices between y and ly_{t_1} in clockwise direction by T . Denote the size of T and degree 2 vertices in T by t and t_0 respectively. Denote the set of vertices between x and rx_{p_1} in clockwise direction by P . Moreover denote the size of P and degree 2 vertices in P by p and p_0 respectively. Finally, denote the set of vertices between y and ry_{q_1} in counterclockwise direction by Q . Moreover denote the size of Q and degree 2 vertices in Q by q and q_0 respectively.

Obviously $s = s_0 + s_1, t = t_0 + t_1, p = p_0 + p_1$ and $q = q_0 + q_1$. Moreover, $n_1 = s + t - 1$ and $n_2 = p + q - 1$. Next we count the number of crossing P_5 's with respect to the chord e , and we do this type-wise.

1. Type-I crossing P_5 's with respect to e : First we count the number of crossing P_5 's of the form (lx_k, x, y, ry_j, v) . It can be checked that for a vertex $v \in Q$, the number of cherries with terminal vertices y and v is at most 2. So, the number of Type-I crossing P_5 's of the form (lx_k, x, y, ry_j, v) is at most $2s_1q$. Considering the other possibilities, the number of Type-I crossing P_5 's is at most $2(s_1q + q_1s + t_1p + p_1t)$, which is at most $4sq + 4tp$.
2. Type-II(A) crossing P_5 's with respect to e : It can be checked that the number of Type-II(A) crossing P_5 's with respect to e is at most $s_1t_1 + p_1q_1 + 2(s_1q_1 + t_1p_1)$, which is at most $st + pq + 2(sq + tp)$.
3. Type-II(B) crossing P_5 's with respect to e : We ignore this kind of crossing P_5 's as the number is linear.
4. Type-III(A) crossing P_5 's with respect to e : First we count number of crossing P_5 's of the form $(v_1, lx_k, x, rx_i, v_1)$. Clearly for a vertex $v_1 \in S$ the number of cherries with terminal vertices v_1 and x is at most 2. Moreover, for a vertex $v_2 \in P$, the number of cherries with terminal vertices x and v_2 is at most 2. Therefore, number of Type-III(A) crossing P_5 of the form $(v_1, lx_k, x, rx_i, v_1)$ is $4sp$. Hence considering the other possibility, the number of Type-III(A) crossing P_5 's in G is $4sp + 4tq$.

5. Type-III(B) crossing P_5 's with respect to e : First we count the number of Type-III(B) crossing P_5 's of the form $(lx_k, x, rx_i, v_1, v_2)$, where $k \in [s_1], i \in [p_1]$ and $v_1, v_2 \in P$. Considering the structure of G of the claim, the edge $\{v_1, v_2\}$ is either $\{rx_i, rx_{i+1}\}$ or $\{v, rx_i\}$ or $\{v, rx_{i+1}\}$, for some $i \in [p_1 - 1]$ and v a degree 2 vertex in P . For each edge $\{rx_i, rx_{i+1}\}$, $i \in [p_1 - 1]$, the number of 3-paths of the form (x, h, rx_i, rx_{i+1}) or (x, h, rx_{i+1}, rx_i) is 2, namely $(x, rx_{i+2}, rx_{i+1}, rx_i)$ and $(x, rx_{i-1}, rx_i, rx_{i+1})$. Let $v \in P$ be a degree 2 vertex be an interior vertex between rx_i and rx_{i+1} in clockwise direction. Notice that we have p_1 number of edges of the form $\{rx_i, rx_{i+1}\}$. Next we count the number of 3-paths of the form (x, h, rx_i, v) and (x, h, v, rx_i) and similar argument can be given for the number of 3-paths of the form (x, h, rx_{i+1}, v) and (x, h, v, rx_{i+1}) . There are only three 3-paths of the form (x, h, rx_i, v) and (x, h, v, rx_i) , namely (x, rx_{i-1}, rx_i, v) , (x, rx_{i+1}, v, rx_i) and (x, rx_{i+1}, rx_i, v) . Notice that for each degree 2 vertex $v \in P$, we have 2 edges this kind, namely $\{v, rx_i\}$ and $\{v, rx_{i+1}\}$.

Thus, the number of 3-paths of the form (x, rx_i, v_1, v_2) , where $i \in [p_1]$ and $v_1, v_2 \in P$ is at most $2p_1 + 6p_0$. Therefore, the number of Type-III(B) crossing P_5 's of the form $(lx_k, x, rx_i, v_1, v_2)$, where $k \in [s_1], i \in [p_1]$ and $v_1, v_2 \in P$ is at most $s_1(2p_1 + 6p_0)$.

With similarly, the number of Type-III(B) crossing P_5 's of the form $(rx_i, x, rx_k, v_1, v_2)$, where $k \in [s_1], i \in [p_1]$ and $v_1, v_2 \in S$ is at most $p_1(2s_1 + 6s_0)$.

Thus taking the sum of the two and $p_0 = p - p_1$ and $s_0 = s - s_1$ the number of Type-III(B) crossing P_5 's with respect to e and containing x is at most $4s_1p_1 + 6s_1(p - p_1) + 6p_1(s - s_1)$.

Notice that $p_1 \in [1, p]$ and $s_1 \in [1, s]$. Now define a function $g : [1, s] \times [1, p] \rightarrow \mathbb{R}$ as $g(s_1, p_1) := 4s_1p_1 + 6s_1(p - p_1) + 6p_1(s - s_1)$. It can be checked that g attains maximum value at the critical point $(\frac{3}{4}s, \frac{3}{4}p)$. Moreover at this point the value of g is $g(\frac{3s}{4}, \frac{3p}{4}) = \frac{9}{2}ps$. That means the number of Type-III(B) crossing P_5 's containing the vertex x is at most $\frac{9ps}{2}$.

With similar argument, the number of Type-III(B) crossing P_5 's containing y is at most $\frac{9}{2}tq$. Therefore, the number of Type-III(B) crossing P_5 's with respect to e is at most $\frac{9}{2}ps + \frac{9}{2}tq$.

Summing up all the upper bound, the number of crossing P_5 's with respect to e is at most $(4sq + 4tp) + (st + pq + 2sq + 2tp) + (4sp + 4tq) + (\frac{9}{2}ps + \frac{9}{2}tq)$, which is $8.5ps + 8.5tq + 6sq + 6tp + st + pq$. Considering that $q = n_1 - p$ and $t = n_2 - s$, the last expression is equal to $8.5n_1n_2 + 5sp + n_1s + n_2q - s^2 - p^2 - \frac{5}{2}n_2s - \frac{5}{2}n_1p$. Notice that $s \in [1, n_1]$ and $p \in [1, n_2]$. Define a function $h(s, p) : [1, n_1] \times [1, n_2] \rightarrow \mathbb{R}$ as $h(s, p) := 8.5n_1n_2 + 5sp + n_1s + n_2q - s^2 - p^2 - \frac{5}{2}n_2s - \frac{5}{2}n_1p$. We treat h as a continuous real valued function in the rectangular region to find the maximum value of h .

It can be checked that h possesses a critical point $(\frac{1}{2}n_1, \frac{1}{2}n_2)$. The values of h at the points $(1, 1)$, $(1, n_2)$, $(n_1, 1)$, (n_1, n_2) and $(\frac{1}{2}n_1, \frac{1}{2}n_2)$ are respectively, $f(1, 1) = \frac{17}{2}n_1n_2 - \frac{3}{2}n_1 - \frac{3}{2}n_2 + 3$, $h(1, n_2) = 6n_1n_2 + n_2 + \frac{5}{2}n_2 - 1$, $h(n_1, 1) = n_1n_2 + n_2 + \frac{5}{2}n_1 - 1$, $h(n_1, n_2) = \frac{17}{2}n_1n_2$ and $h(\frac{1}{2}n_1, \frac{1}{2}n_2) = \frac{29}{4}n_1n_2 + \frac{1}{4}n_1^2 + \frac{1}{4}n_2^2 = \frac{17}{2}n_1n_2 + \frac{1}{4}n_1^2 + \frac{1}{4}n_2^2 - \frac{5}{4}n_1n_2$.

To finish our proof we need to show that $h(\frac{1}{2}n_1, \frac{1}{2}n_2) = \frac{17}{2}n_1n_2 + O(n)$. Indeed, remember that $n = n_1 + n_2$ and $\frac{n}{3} \leq n_1 \leq \frac{2}{3}n$. Define a function $f(n_1) : [\frac{1}{3}n, \frac{2}{3}n] \rightarrow \mathbb{R}$ as $f(n_1) = \frac{1}{4}n_1^2 + \frac{1}{4}(n - n_1)^2 - \frac{5}{4}n_1(n - n_1)$. It is easy to check that f attains maximum value when $n_1 = \frac{n}{2}$. Moreover the maximum value of f is $f(\frac{1}{2}n) = -\frac{3}{16}n^2$. This completes the proof of Claim 5. \square

From Claim 5, without loss of generality we may assume that $i^* \in [p_1 - 1]$ is the smallest integer such that there is at least two interior vertices in clockwise direction between rx_{i^*} and rx_{i^*+1} . Hence, there is no or one interior vertex in clockwise direction between rx_i and rx_{i+1} , for each $i \in [i^* - 1]$. Notice that $\{rx_{i^*}, rx_{i^*+1}\}$ is an edge in G .

Let I^* be the set of interior vertices between $rx_{i^*}^1$ and rx_{i^*+1} (clockwise direction) which are adjacent to rx_{i^*} . Denote $I = I^* \cup \{rx_{i^*+1}\}$.

Let G' be the maximal outerplanar graph obtained from G with three consecutive operations. Call the operations collectively as a *reduction operation*.

1. Delete the edges $\{rx_{i^*}, w\}$, for each $w \in I$.
2. Add the edges $\{rx_{i^*}^1, w\}$, for each $w \in I$. Where $rx_{i^*}^1$ is the first interior vertex in clockwise direction between rx_{i^*} and rx_{i^*+1} . Notice that there is exactly one vertex in I which is adjacent to $rx_{i^*}^1$. Denote the vertex by w^* . Notice that w^* can be rx_{i^*+1} .

3. Delete the multiple edge which results from procedure (2) and finally add the edge $\{x, rx_{i^*}^1\}$.

We complete our proof by showing the following important claim.

Claim 6. $\mathcal{N}_e(P_5, G) \leq \mathcal{N}_e(P_5, G')$.

Proof. It is enough to show that for each crossing P_5 's with respect to e containing the edges $\{rx_{i^*}, w\}$ in G , where $w \in I$, we correspondingly find a unique crossing P_5 's with respect to e in G' but not in G . We distinguish two cases considering the position of i^* .

Case 1: $i^* \neq p_1 - 1$.

- Type-I crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$: Type-I crossing P_5 's in G containing $\{rx_{i^*}, w\}$ are either $(ly_\ell, y, x, rx_{i^*}, w)$ or $(ly_\ell, y, x, rx_{i^*+1}, rx_{i^*})$, $\ell \in [t_1]$.

For $(ly_\ell, y, x, rx_{i^*}, w)$, we take the crossing P_5 's in G' of the form $(ly_\ell, y, x, rx_{i^*}^1, w)$.

We consider two cases concerning the crossing P_5 's of the form $(ly_\ell, y, x, rx_{i^*+1}, rx_{i^*})$ in G . If $w^* = rx_{i^*+1}$, we take the replacement crossing P_5 $(ly_\ell, y, x, rx_{i^*}^1, rx_{i^*})$. If $w^* \neq rx_{i^*+1}$, we take the replacing crossing P_5 $(ly_\ell, y, x, rx_{i^*+1}, rx_{i^*}^1)$.

- Type-II(A) crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$: It can be seen that there is no Type-II(A) crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$.
- Type-II(B) crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$: In this case the only crossing P_5 's are of the form $(y, lx_{s_1}, x, rx_{i^*}, w)$ and $(y, lx_{s_1}, x, rx_{i^*+1}, rx_{i^*})$.

For the former crossing P_5 's we can take the replacing crossing P_5 's of the form $(y, lx_{s_1}, x, rx_{i^*}^1, w)$. For the later case we consider two cases. If $w^* = rx_{i^*+1}$, then we take the replacing crossing P_5 $(y, lx_{s_1}, x, rx_{i^*}^1, rx_{i^*})$. If $w^* \neq rx_{i^*+1}$, we take the crossing P_5 of the form $(y, lx_{s_1}, x, rx_{i^*+1}, rx_{i^*}^1)$.

- Type-III(A) crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$: The crossing P_5 's are of the form $(z, lx_k, x, rx_{i^*}, w)$ and $(z, lx_k, x, rx_{i^*+1}, rx_{i^*})$, $k \in [s_1]$ and z ($\neq y$) is a vertex adjacent to rx_k .

For the former case we take the crossing P_5 's in G' of the form $(z, lx_k, x, rx_{i^*}^1, w)$. For the latter case we consider two cases. If $w^* = rx_{i^*+1}$, we take the replacing crossing P_5 , $(z, lx_k, x, rx_{i^*}^1, rx_{i^*})$. If $w^* \neq rx_{i^*+1}$, we take replacement crossing P_5 of the form $(z, lx_k, x, rx_{i^*+1}, rx_{i^*}^1)$.

- Type-III(B) crossing P_5 's in G containing the edges $\{rx_{i^*}, w\}$: In this case we distinguish two cases.

Case 1.1: $i^* \neq p_1 - 2$.

The crossing P_5 's in G containing $\{rx_{i^*}, w\}$ and their respective replacement crossing P_5 's in G' are considered below.

1. For crossing P_5 's of the form $(lx_k, x, rx_{i^*-1}, rx_{i^*}, w)$, where $k \in [s_1]$ and $w \neq w^*$, we take the replacement $(lx_k, x, rx_{i^*}, rx_{i^*}^1, w)$. Notice that when $w = w^*$, $\{rx_{i^*}^1, w^*\}$ is already an edge in G . In this case we replace the crossing P_5 $(lx_k, x, rx_{i^*-1}, rx_{i^*}, w^*)$ with $(lx_k, x, rx_{i^*}^1, rx_{i^*}^2, rx_{i^*}^3)$. Recall that there are at least two interior vertices between rx_{i^*} and rx_{i^*+1} in clockwise direction. If there are exactly two interior vertices, $rx_{i^*}^3 = rx_{i^*+1}$.
2. For crossing P_5 's of the form $(lx_k, x, rx_{i^*}, w, u)$, where $k \in [s_1]$ and u is a vertex adjacent to w and $u \neq rx_{i^*}^1$, we replace it with by $(lx_k, x, rx_{i^*}^1, w, u)$. For the crossing P_5 's of the form $(lx_k, x, rx_{i^*}, w^*, rx_{i^*}^1)$, we replace it by $(z_1, z_2, lx_k, x, rx_{i^*}^1)$, where (z_1, z_2, lx_k) is a 2-path with respect to vertex alignment in the outer cycle of G in clockwise direction.
3. For the crossing P_5 's of the form $(lx_k, x, rx_{i^*+1}, rx_{i^*}, u)$, where $k \in [s_1]$ and u is a vertex adjacent to rx_{i^*} . We may consider two cases.
 If $w^* = rx_{i^*+1}$, the only crossing P_5 's of the stated form are $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*}^1)$, $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*-1}^1)$ and $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*-1}^1)$. The last crossing P_5 may or may not exist, it depends with the existence of the vertex $rx_{i^*-1}^1$. The respective replacement crossing P_5 's we take are $(z_2, lx_k, x, rx_{i^*}^1, rx_{i^*}^2)$, $(lx_k, x, rx_{i^*}^1, rx_{i^*}, rx_{i^*-1}^1)$ and $(lx_k, x, rx_{i^*}^1, rx_{i^*}, rx_{i^*-1}^1)$, where z_2 is the vertex as defined in(2).
 On the other hand, for the case that $w^* \neq rx_{i^*+1}$, the crossing P_5 's of the stated form are $(lx_k, x, rx_{i^*+1}, rx_{i^*}, w)$, $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*}^1)$, $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*-1}^1)$ and $(lx_k, x, rx_{i^*+1}, rx_{i^*}, rx_{i^*-1}^1)$. The last crossing P_5 may or may not exist. In this case we take the the replacement crossing P_5 's, $(lx_k, x, rx_{i^*+1}, rx_{i^*}^1, w)$, $(lx_k, x, rx_{i^*+1}, rx_{i^*}^1, rx_{i^*})$, $(lx_k, x, rx_{i^*}^1, rx_{i^*}, rx_{i^*-1}^1)$ and $(lx_k, x, rx_{i^*}^1, rx_{i^*}, rx_{i^*-1}^1)$ respectively.
4. For the case that $w^* \neq rx_{i^*+1}$, we have a crossing P_5 of the form $(lx_k, x, rx_{i^*+1}, f, rx_{i^*})$, where f is the second from the last rx_{i^*+1} in I such that $\{rx_{i^*}, f\}$ is an edge in G . In this case we take replacement crossing P_5 $(z_3, z_4, lx_k, x, rx_{i^*}^1)$. where (z_3, z_4, lx_k) is a 2-path with respect to vertex alignment in the outer cycle of the G in counterclockwise direction..
5. For the crossing P_5 of the form $(lx_k, x, rx_{i^*+2}, rx_{i^*+1}, rx_{i^*})$. We distinguish two cases. If $w^* = rx_{i^*+1}$, then we take the replacement crossing P_5 $(z_4, lx_k, x, rx_{i^*}^1, rx_{i^*}^2)$. If $w^* \neq rx_{i^*+1}$, we take the replacement crossing P_5 $(lx_k, x, rx_{i^*+2}, rx_{i^*+1}, rx_{i^*}^1)$.

Case 1.2: $i^* = p_1 - 2$.

Apart from the crossing P_5 's considered above, the crossing P_5 's which is not considered yet are Type-III(B) crossing P_5 of the form $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-2})$, where

$\ell \in [t_1]$. Here we distinguish two cases. If $w^* = rx_{p_1-1}$, we take the replacing crossing P_5 , $(ly_\ell, y, x, rx_{p_1-2}^1, rx_{p_1-2})$. If $w^* \neq rx_{p_1-1}$, we take the replacing crossing P_5 $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-2}^1)$.

Case 2: $i^* = p_1 - 1$.

For completeness we consider crossing P_5 's of each type containing the edges $\{rx_{p_1-1}, w\}$, where $w \in I$.

- Type-I crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$: Apart from crossing Type-I crossing P_5 's considered in Case 1, the Type-I crossing P_5 which is not considered in this case is $(lx_k, x, y, rx_{p_1}, rx_{p_1-1})$. We consider two cases. If $w^* = rx_{p_1}$, then we take the replacement crossing P_5 's $(z_4, rx_k, x, rx_{p_1-1}^1, rx_{p_1-1}^2)$, where the z_4 is the vertex whose definition is given in Case 1.1 (4). If $w^* \neq rx_{p_1}$, we take the replacement crossing P_5 of the form $(lx_k, x, y, rx_{p_1}, rx_{p_1-1}^1)$.
- Type-II(A) crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$: It can be seen that there is no Type-II(A) crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$.
- Type-II(B) crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$: The crossing P_5 's of this kind which are not yet considered are $(lx_k, x, rx_{p_1-1}, rx_{p_1}, y)$ and $(ly_t, y, rx_{p_1}, rx_{p_1-1}, x)$, where $k \in [s_1]$ and $\ell \in [t_1]$. In this case we take the replacement crossing P_5 's of the form $(lx_k, x, rx_{p_1-1}^1, rx_{p_1}, y)$ and $(ly_t, y, rx_{p_1}, rx_{p_1-1}^1, x)$ respectively.
- Type-III(A) crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$: Apart from the crossing P_5 's of Type III(A) stated in Case 1, the following are the new Type-III(A) crossing P_5 's which are not yet considered. These are $(v, ly_\ell, y, rx_{p_1}, rx_{p_1-1})$, where $\ell \in [t_1]$. We consider two cases. If $w^* = rx_{p_1}$, we take the replacement crossing P_5 of the form $(v, ly_\ell, y, x, rx_{p_1-1}^1)$. If $w^* \neq rx_{p_1}$, we take the replacement crossing P_5 's of the form $(v, ly_\ell, y, rx_{p_1}, rx_{p_1-1}^1)$.
- Type-III(B) crossing P_5 's in G containing the edges $\{rx_{p_1-1}, w\}$: In this case we do not have crossing P_5 's which are stated in Case 1.1(5). However we have new Type-III(B) crossing P_5 's. The following are these crossing P_5 's and their respective replacements.

1. Consider the crossing P_5 's of the form $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, u)$. We distinguish two cases. If $w^* = rx_{p_1}$, then there are only three crossing P_5 's of such kind. These are $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-1}^1)$, $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-2})$ and $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-2}^1)$. Notice that the existence of the last crossing P_5 depends on the existence of the vertex $rx_{p_1-2}^1$. We take the following respective replacement crossing P_5 's, $(u_1, ly_\ell, y, x, rx_{p_1-1}^1)$, $(u_2, ly_\ell, y, x, rx_{p_1-1}^1)$ and $(ly_\ell, y, x, rx_{p_1-1}^1, rx_{p_1-1}^2)$ respectively. It can be seen that non of these crossing P_5 's is used in any the previous crossing P_5 's.

If $w^* = rx_{p_1}$, then the crossing P_5 's of such kind are $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, w)$, $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-1}^1)$, $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}, rx_{p_1-2})$ and $(ly_\ell, y, rx_{p_1}, rx_{p_1-1},$

- $rx_{p_1-2}^1$). In this case we take the replacement crossing P_5 's of the form $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}^1, w)$, $(ly_\ell, y, rx_{p_1}, rx_{p_1-1}^1, rx_{p_1-1}^1)$ ($u_1, ly_\ell, y, x, rx_{p_1-1}^1$) and $(u_2, ly_\ell, y, x, rx_{p_1-1}^1)$.
2. For the case that $w^* \neq rx_{p_1}$, we have a crossing P_5 's of the form $(ly_\ell, y, rx_{p_1}, f, rx_{p_1-1}^1)$, where f is second vertex from the last rx_{p_1} in I . In this case we take the replacement crossing P_5 of the form $(ly_\ell, y, lx_{s_1}, x, rx_{p_1-1}^1)$.
 3. Consider the crossing P_5 's of the form $(ly_\ell, y, ry_{q_1-1}, rx_{p_1}, rx_{p_1-1}^1)$. In this case we take the replacement $(ly_\ell, y, rx_{p_1}, x, rx_{p_1-1}^1)$.

Therefore the number of crossing P_5 's with respect to e in G is at most the number of crossing P_5 's with respect to e in G' . This completes the proof of Claim 6. \square

From Claim 6, we can proceed with the reduction operation procedure for each neighbours of x and y in I_1 and I_2 till we reach on the situation that, for each $i \in [p_1 - 1], j \in [q_1 - 1], k \in [s_1 - 1]$ and $\ell \in [t_1 - 1]$, there is no interior or one interior vertex between the pairs (lx_k, lx_{k+1}) in counterclockwise direction, $(ly_\ell, ly_{\ell+1})$ in clockwise direction, (rx_i, rx_{i+1}) in clockwise direction and (ry_j, ry_{j+1}) counterclockwise direction.

Let the resulting graph at the end of a sequence of reduction operations be H . Thus $\mathcal{N}_e(P_5, G) \leq \mathcal{N}_e(P_5, H)$. But by Claim 5, $\mathcal{N}_e(P_5, H) = \frac{17}{2}n_1n_2 + O(n)$. Therefore,

$$\mathcal{N}_e(P_5, G) = \frac{17}{2}n_1n_2 + O(n).$$

This completes the proof of Lemma 7. \square

Next we finish the proof of Theorem 4. Let the graph induced by $I_1 \cup \{x, y\}$ and $I_2 \cup \{x, y\}$ be G_1 and G_2 respectively. Since e is a nice chord, by induction $\mathcal{N}(P_5, G_1) = \frac{17}{4}n_1^2 + O(n)$ and $\mathcal{N}(P_5, G_2) = \frac{17}{4}n_2^2 + O(n)$. From Lemma 7, $\mathcal{N}_e(P_5, G) = \frac{17}{2}n_1n_2 + O(n)$.

Therefore,

$$\begin{aligned} \mathcal{N}(P_5, G) &= \mathcal{N}(P_5, G_1) + \mathcal{N}(P_5, G_2) + \mathcal{N}_e(P_5, G) \\ &= \frac{17}{4}n_1^2 + O(n) + \frac{17}{4}n_2^2 + O(n) + \frac{17}{2}n_1n_2 + O(n) \\ &= \frac{17}{4}(n_1 + n_2)^2 + O(n) \\ &= \frac{17}{4}n^2 + O(n). \end{aligned}$$

This completes the poof of Theorem 4. \square

4 Concluding remarks and conjecture

Considering the complexity of the proof we have for a best asymptotic value of $f_{\mathcal{OP}}(n, P_5)$, it might be not easy to determine a best asymptotic value of the generalized outerplanar Turán number of short paths. We pose the following conjecture related to the generalized outerplanar Turán number of the P_6 .

Conjecture 1. $f_{\mathcal{OP}}(n, P_6) = 11n^2 + \Theta(n)$.

The following construction of an n -vertex maximal outerplanar graph G_n verifies the lower bound is attainable. G_n contains $\frac{n}{2}$ degree-2 vertices and all the remaining $\frac{n}{2} - 1$ vertices are adjacent to a vertex, say v , in G_n (see Figure 12). It can be checked that $\mathcal{N}(P_6, G_n) = 11n^2 + \Omega(n)$.

Figure 12: A maximal outerplanar graph G_n containing roughly $11n^2$ 5-paths.
