

HAUSDORFF DIMENSION AND LEBESGUE MEASURE OF CODIAGONAL OF EMBEDDED VECTOR BUNDLES OVER SUBMANIFOLDS IN EUCLIDEAN SPACE

HANWEN LIU

ABSTRACT. In this paper we study measure theoretical size of the image of naturally embedded vector bundles in $\mathbb{R}^n \times \mathbb{R}^n$ under the codiagonal morphism, i.e. Δ_* in the category of finite dimensional \mathbb{R} -vector spaces. Under very weak smoothness condition we show that codiagonal of normal bundles always contain an open subset of the ambient space, and we give corresponding criterions for the tangent bundles. For any differentiable hypersurface we show that the codiagonal of its tangent bundle has non-empty interior, unless the hypersurface is contained in a hyperplane. Assuming further smoothness (e.g. twice differentiable) we show that union of any family of hyperplanes that covers the hypersurface has maximal possible Hausdorff dimension. We also define and study a notion of degeneracy of embedded C^1 vector bundles over a C^1 submanifold and show as a corollary that if the base manifold has at least one non-inflection point then codiagonal of any C^1 line bundle over it has positive Lebesgue measure. Finally we show that codiagonal of any line bundle over an n -dimensional ellipsoid or a convex curve has non-empty interior, and the same assertion also holds for any non-tangent line bundle over a hyperplane.

1. INTRODUCTION AND PREPARATION LEMMAS

In this paper all base fields are assumed to be the field of real numbers \mathbb{R} , and all vector spaces $\mathbb{R}^n := (\mathbb{R}^n, \langle \cdot, \cdot \rangle)$ are assumed to be equipped with the standard Euclidean structure.

For any subset $X \subseteq \mathbb{R}^n$ we denote by $i_X : X \rightarrow \mathbb{R}^n$ the canonical inclusion and by $\text{int } X, \bar{X}, \partial X$ its interior, closure, boundary (in the induced topology) resp. We denote $\mathbb{R}_+ := \{x \in \mathbb{R} \mid x > 0\}$, and I will always be the open interval $] -\pi, \pi[$. As usual, $\mathbb{D}^n := \{x \in \mathbb{R}^n \mid \|x\| \leq 1\}$ is the n -dimensional unit disk, $\mathbb{S}^{n-1} := \{x \in \mathbb{R}^n \mid \|x\| = 1\}$ is the $(n-1)$ -dimensional unit sphere, and $B_r^n(a) := \{x \in \mathbb{R}^n \mid \|x - a\| < r\}$ is the n -ball with center $a \in \mathbb{R}^n$ and radius r . For simplicity we write $B_r^n := B_r^n(0)$.

For any map f denote by Γ_f its graph, and for any differentiable f denote by $J_x f$ its Jacobian at x . Linear functions and linear mappings on an open subset of an Euclidean space are defined to be the functions and mappings with constant differential.

Moreover we denote by \dim and $\dim_{\mathcal{H}}$ the topological and Hausdorff dimension resp. and by \mathcal{L}^n the n -dimensional Lebesgue measure.

1.1. Manifolds in Euclidean Space. In this paper, a topological d -submanifold (with boundary) M of \mathbb{R}^n is a topological subspace of \mathbb{R}^n s.t. M is a topological d -manifold (with boundary) in the induced topology. Moreover, topological d -submanifold M is said to be a C^r submanifold iff its transition functions are of class C^r . All manifolds are assumed to be connected.

In this paper we also consider the following two notions of smoothness.

Definition 1.1.1. A topological submanifold M is said to be k -th differentiable iff for any $p \in M$, at the vicinity of p , M coincides with the graph of a k -th differentiable map f . For simplicity once differentiable submanifolds are abbreviated as differentiable submanifolds.

Definition 1.1.2. A C^1 submanifold is said to be Lipschitz-continuously differentiable iff for any $p \in M$, at the vicinity of p , M coincides with the graph of a C^1 map f with locally Lipschitz differential.

Since C^1 maps are locally Lipschitz, by definition we have that any C^2 submanifold is Lipschitz-continuously differentiable.

As usual, a 1-submanifold is called a regular curve, a 2-submanifold is called a regular surface, a submanifold of codimension 1 is called a hypersurface.

Let M be a k -submanifold of \mathbb{R}^m and N be a ℓ -submanifold of \mathbb{R}^n then the product manifold $M \times N := \{(p, q) \in \mathbb{R}^{n+m} \mid p \in M, q \in N\}$ is a $(k + \ell)$ -submanifold of \mathbb{R}^{n+m} . For any two maps $f : A \rightarrow C$ and $g : B \rightarrow D$ we define $f \times g : A \times B \rightarrow C \times D$ by $f \times g(a, b) := (f(a), g(b))$, then $\Gamma_{f \times g} = \Gamma_f \times \Gamma_g$. For example, if f, g are differentiable maps (from open subsets in Euclidean spaces to Euclidean spaces), then Γ_f, Γ_g are differentiable submanifolds and $\Gamma_{f \times g}$ is their product submanifold.

Remark 1.1.3. Notice that the implicit and inverse function theorem hold for differentiable maps (Theorem 2 and 3 in [2]), and differentiable maps with differentiable local inverses form a pseudo group \mathcal{G} and hence defines a manifold structure. The differentiable submanifold in Definition 1.1.1 clearly has local parametrization $\mathbf{f}(x) = (x, f(x))$ and admits a differentiable chart, and hence a \mathcal{G} -structure.

The similar assertion holds also for Lipschitz-continuously differentiable submanifolds in Definition 1.1.2.

1.2. Substantial and Nonlinear Submanifolds. Recall that a submanifold is said to be substantial iff it is not contained in any hyperplane of the ambient space.

An affine plane in \mathbb{R}^3 is not substantial, and the twisted quartic $\mathcal{X} : t \mapsto (t, t^2, t^3, t^4)$ is a well-known example of a substantial C^ω curve in \mathbb{R}^4 .

Notice that the curvature of \mathcal{X} is non-vanishing. Another nontrivial example can be constructed as follows.

Recall that for any C^1 regular curve $g : I \rightarrow \mathbb{R}^n$ the tangent developable Σ of g is parametrized by $\mathbf{x}(u, v) = g(u) + vg'(u)$, $u \in I, v \in \mathbb{R}$, and g is a cuspidal edge of Σ .

We denote by Σ_+ the one-sided tangent developable of g parametrized by $\mathbf{x}(u, v) = g(u) + vg'(u)$, $u \in I, v \in \mathbb{R}_+$.

Proposition 1.2.1. *Let $r \geq 1$ and $g : I \rightarrow \mathbb{R}^n$ be a substantial C^{r+1} regular curve with non-vanishing curvature, then the one-sided tangent developable of Σ_+ of g is a substantial C^r regular surface.*

Proof. Since $\frac{\partial \mathbf{x}}{\partial u} = g'(u) + vg''(u)$ and $\frac{\partial \mathbf{x}}{\partial v} = g'(u)$, we have $\left\| \frac{\partial \mathbf{x}}{\partial u} \times \frac{\partial \mathbf{x}}{\partial v} \right\| = \|(g'(u) + vg''(u)) \times g'(u)\| = v \|g''(u) \times g'(u)\|$. Since $v > 0$, we have that $\left\| \frac{\partial \mathbf{x}}{\partial u} \times \frac{\partial \mathbf{x}}{\partial v} \right\| > 0$ iff $\|g''(u) \times g'(u)\| > 0$. Since the curvature κ of g is $\kappa = \frac{\|g''(u) \times g'(u)\|}{\|g'(u)\|^3} > 0$, we obtain that $\|g''(u) \times g'(u)\| > 0$. Therefore

$\left\| \frac{\partial \mathbf{x}}{\partial u} \times \frac{\partial \mathbf{x}}{\partial v} \right\| \neq 0$ and hence Σ_+ is a regular surface.

Moreover $\mathbf{x}(u, v) = g(u) + vg'(u)$ is clearly C^r . It remains to prove that Σ_+ is substantial.

Provided that Σ_+ is not substantial then \exists hyperplane $\Pi \subseteq \mathbb{R}^4$ s.t. $\Sigma_+ \subseteq \Pi$. Since $\forall u \in I \lim_{v \rightarrow 0^+} \mathbf{x}(u, v) = g(u)$, we have that $\forall p \in g, p$ is a limit point of Σ_+ . Since Π is closed, we have that $g \subseteq \Pi$, and hence g is not substantial, contradiction. ■

We give a definition of a notion related to the substantialness.

Definition 1.2.2. A submanifold M of \mathbb{R}^n is said to be linear iff \exists affine subspace $\Pi \subseteq \mathbb{R}^n$ s.t. M is an open subset of Π . Otherwise M is said to be nonlinear.

It is clear by definition that a linear substantial submanifold is an open subset in the ambient space, and for hypersurfaces the nonlinearity is equivalent to substantialness.

In this paper the nonlinearity is an important notion. We shall introduce several preparation lemmas about the nonlinearity.

1.3. Restriction of the Domain of Nonlinearity. Firstly we show that the nonlinearity of a function is a local property.

Lemma 1.3.1. *Let Ω be a connected open subset of \mathbb{R}^d and $f : \Omega \rightarrow \mathbb{R}$ be a real function. If for any $x \in \Omega$ (f, x) is the germ of a linear function, then f is linear.*

Proof. Since $\forall x \in \Omega$ (f, x) is a germ of linear (and hence harmonic) function, we have that f is harmonic on Ω . Fix $x_0 \in \Omega$, by assumption \exists linear function $g : \Omega \rightarrow \mathbb{R}$ s.t. $(f, x_0) = (g, x_0)$. Since Ω is a connected open subset of \mathbb{R}^d , by the analytic continuation principle we have $f \equiv g$ and hence f is linear. ■

Corollary 1.3.2. *Let Ω be a connected open subset of \mathbb{R}^d and $f : \Omega \rightarrow \mathbb{R}$ is a nonlinear function, then $\exists x_0 \in \Omega$ s.t. (f, x_0) is the germ of a nonlinear function.*

Corollary 1.3.3. *Let Ω be a connected open subset of \mathbb{R}^d and $f : \Omega \rightarrow \mathbb{R}^m$ is a nonlinear map, then $\exists x_0 \in \Omega$ s.t. \forall open neighborhood U of x_0 , $f|_U$ is nonlinear.*

Proof. Recall that a map $f = (f^1, \dots, f^m)$ is nonlinear iff $\exists i \in \{1, \dots, m\}$ s.t. f^i is a nonlinear function. Apply Corollary 1.3.2. ■

Remark 1.3.4. From Corollary 1.3.3 we obtain that for any nonlinear map f defined on Ω , up to rigid motion and homothety we may assume that $I^d \subseteq \Omega$ and f is nonlinear on I^d .

As an application we show that the nonlinearity of a submanifold is a local property.

Lemma 1.3.5. *If a differentiable submanifold M of \mathbb{R}^n is locally graph of linear maps at all $p \in M$ then M is a linear submanifold.*

Proof. By assumption clearly M admits an analytic atlas and hence is a C^ω submanifold. Fix $p \in M$, \exists local chart U of M at the vicinity of p and an affine subspace $\Pi \subseteq \mathbb{R}^n$ s.t. $M \cap \Pi \supseteq U$. Since U is open in M and Π , and Π is complete, by the uniqueness theorem of C^ω submanifolds, M is an open subset of Π , i.e. a linear submanifold. ■

Corollary 1.3.6. *Let M be a nonlinear differentiable d -submanifold of \mathbb{R}^n , then up to rigid motion and homothety, \exists local chart U of M s.t. $U = \Gamma_f$ where $f : I^d \rightarrow \mathbb{R}^{n-d}$ is a nonlinear differentiable map.*

Proof. By Lemma 1.3.5 \exists local chart U of M s.t. $U = \Gamma_f$ where $f : \Omega \rightarrow \mathbb{R}^{n-d}$ is a nonlinear differentiable map. By Remark 1.3.4 wlog we assume $\Omega = I^d$. ■

We now introduce another type of restriction of domain of nonlinearity. We start with several lemmas.

Recall that a monomial $x^\alpha \in \mathbb{R}[x_1, \dots, x_n]$ is said to be square free iff $\|\alpha\|_\infty \leq 1$, where $\alpha \in \mathbb{N}^n$ is the multi-index. For simplicity we denote $\Xi_n := \text{span}_{\mathbb{R}} \{x^\alpha \in \mathbb{R}[x_1, \dots, x_n] \mid \|\alpha\|_\infty \leq 1\}$ as a space of polynomial functions defined on I^n .

Lemma 1.3.7. *Let $f : I^n \rightarrow \mathbb{R}$ be a real function s.t. $\forall i = 1, \dots, n \exists$ real function $a_i, b_i : I^{n-1} \rightarrow \mathbb{R}$ s.t. $f(x_1, \dots, x_n) = a_i(x_1, \dots, \hat{x}_i, \dots, x_n)x_i + b_i(x_1, \dots, \hat{x}_i, \dots, x_n)$, then $f \in \Xi_n$.*

Proof. Apply induction on n .

The statement holds trivially for $n = 1$.

Assume that the statement holds for $n = k$. Take any $f : I^{k+1} \rightarrow \mathbb{R}$ s.t. $\forall i = 1, \dots, k+1 \exists a_i, b_i : I^k \rightarrow \mathbb{R}$ s.t. $f(x_1, \dots, x_{k+1}) = a_i(x_1, \dots, \hat{x}_i, \dots, x_{k+1})x_i + b_i(x_1, \dots, \hat{x}_i, \dots, x_{k+1})$. For any $t \in I, \forall i = 1, \dots, k$ define $a_{i,t}, b_{i,t} : I^{k-1} \rightarrow \mathbb{R}$ by $a_{i,t}(y_1, \dots, y_{k-1}) := a_i(y_1, \dots, y_{k-1}, t), b_{i,t}(y_1, \dots, y_{k-1}) := b_i(y_1, \dots, y_{k-1}, t)$, then $f_t(x_1, \dots, x_k) := f(x_1, \dots, x_k, t) = a_i(x_1, \dots, \hat{x}_i, \dots, x_k, t)x_i + b_i(x_1, \dots, \hat{x}_i, \dots, x_k, t) = a_{i,t}(x_1, \dots, \hat{x}_i, \dots, x_k)x_i + b_{i,t}(x_1, \dots, \hat{x}_i, \dots, x_k)$. By the induction hypothesis $f_t \in \Xi_k$. Since $b_{k+1}(x_1, \dots, x_k) = a_{k+1}(x_1, \dots, x_k) \cdot 0 + b_{k+1}(x_1, \dots, x_k) = f(x_1, \dots, x_k, 0) = f_0(x_1, \dots, x_k), a_{k+1}(x_1, \dots, x_k) + b_{k+1}(x_1, \dots, x_k) = a_{k+1}(x_1, \dots, x_k) \cdot 1 + b_{k+1}(x_1, \dots, x_k) = f(x_1, \dots, x_k, 1) = f_1(x_1, \dots, x_k)$, we have $b_{k+1} = f_0 \in \Xi_k$ and $a_{k+1} = (a_{k+1} + b_{k+1}) - b_{k+1} = f_1 - f_0 \in \Xi_k$. Since $f(x_1, \dots, x_k) = a_{k+1}(x_1, \dots, x_{k-1})x_k + b_{k+1}(x_1, \dots, x_{k-1})$, it is clear that $f = a_{k+1}x_{k+1} + b_{k+1} \in \Xi_{k+1}$. Therefore the statement holds for $n = k + 1$.

This concludes the proof. ■

Lemma 1.3.8. *Let $f : I^n \rightarrow \mathbb{R}$ be a real function, if for any isometric embedding $\ell : I \rightarrow I^n$ we have $f \circ \ell$ is a linear function, then f is a linear function.*

Proof. For any $i = 1, \dots, n, \forall a_1, \dots, \hat{a}_i, \dots, a_n \in I$, denote $\alpha := (a_1, \dots, a_{i-1}, 0, a_{i+1}, \dots, a_n), \beta := (\underbrace{0, \dots, 0}_{i-1}, \underbrace{1, 0, \dots, 0}_{n-i})$, and define $\ell : I \rightarrow I^n$ by $\ell(t) = \alpha + t\beta$, then by assumption $f(a_1, \dots, a_{i-1}, t, a_{i+1}, \dots, a_n) = f \circ \ell(t)$ is linear. Therefore we have that $f = f(x_1, \dots, x_n)$ is linear in x_i for any $i = 1, \dots, n$. By Lemma 1.3.7. $f \in \Xi_n$, and in particular f is a polynomial.

Provided that $\deg f \geq 2$, then define $\ell_\Delta : I \rightarrow I^n$ by $\ell_\Delta(t) = \left(\frac{t}{\sqrt{n}}, \dots, \frac{t}{\sqrt{n}}\right)$, then ℓ_Δ is an isometric embedding but $f \circ \ell_\Delta(t) = f\left(\frac{t}{\sqrt{n}}, \dots, \frac{t}{\sqrt{n}}\right)$ is a polynomial in t with degree ≥ 2 and hence nonlinear, contradiction.

Therefore f is a polynomial of $\deg f \leq 1$, i.e. a linear function. ■

Corollary 1.3.9. *Let Ω be a connected open subset of \mathbb{R}^n and $f : \Omega \rightarrow \mathbb{R}$ is a nonlinear function, then up to rigid motion and homothety we have $I^n \subseteq \Omega$ and $f_0(t) := f(0, \dots, 0, t), t \in I$ is a nonlinear function.*

Proof. Apply Remark 1.3.4 and Lemma 1.3.8. ■

Lemma 1.3.10. *Let $\{f_n(x) = a_n x + b_n\}_{n \in \mathbb{N}}$ be a sequence of linear functions on I , if $\{f_n\}_{n \in \mathbb{N}}$ converges weakly then $\exists a, b \in \mathbb{R}$ s.t. $\lim_{n \rightarrow \infty} a_n = a, \lim_{n \rightarrow \infty} b_n = b$ and $f_n(x) \xrightarrow{w} f(x) = ax + b$ on I as $n \rightarrow \infty$.*

Proof. Since $\{f_n\}_{n \in \mathbb{N}}$ converges pointwise, we have that $\exists a, b \in \mathbb{R}$, s.t. $\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} (f_n(1) - f_n(0)) = \lim_{n \rightarrow \infty} f_n(1) - \lim_{n \rightarrow \infty} f_n(0) =: a$ and $\lim_{n \rightarrow \infty} b_n = \lim_{n \rightarrow \infty} f_n(0) =: b$. Therefore $\forall x \in I$, $\lim_{n \rightarrow \infty} f_n(x) = \lim_{n \rightarrow \infty} (a_n x + b_n) = x \lim_{n \rightarrow \infty} a_n + \lim_{n \rightarrow \infty} b_n = ax + b = f(x)$, i.e. $f_n \xrightarrow{w} f$. \blacksquare

Proposition 1.3.11. *Let Ω be a connected open subset of \mathbb{R}^n and $f : \Omega \rightarrow \mathbb{R}$ is a nonlinear continuous function, then up to rigid motion and homothety we have $I^n \subseteq \Omega$ and $\exists \delta > 0$ s.t. $\forall x \in B_\delta^{n-1} \subseteq I^{n-1}$ we have $f_x(t) := f(x^1, \dots, x^{n-1}, t)$, $t \in I$ is a nonlinear continuous function.*

Proof. By Corollary 1.3.9 up to rigid motion and homothety we have $I^n \subseteq \Omega$ and $f_0(t) := f(0, \dots, 0, t)$, $t \in I$ is a nonlinear function.

Provided that $\forall \varepsilon > 0, \exists x \in B_\varepsilon^{n-1} \subseteq I^{n-1}$ s.t. $f_x(t) := f(x^1, \dots, x^{n-1}, t)$, $t \in I$ is linear. Take any sequence $\{x_n\}_{n \in \mathbb{N}} \subseteq B_\varepsilon$ with $\lim_{n \rightarrow \infty} x_n = 0$, then by the continuity of f , $f_{x_n}(t) \xrightarrow{w} f_0(t)$. Since $\{f_{x_n}\}_{n \in \mathbb{N}}$ is a sequence of linear function, by Lemma 1.3.10 is linear, contradiction.

Therefore $\exists \delta > 0$ s.t. $\forall x \in B_\delta^{n-1} \subseteq I^{n-1}$ we have f_x is nonlinear, moreover it is clear that f_x is continuous. \blacksquare

1.4. The Osculating Spaces and Normal Spaces. We discuss several important notions related to submanifolds, these notions will be used frequently throughout this paper.

As usual, for a point on a differentiable (or C^r) submanifold the tangent space at this point is defined to be the image of the differential of the parametrization map at this point.

For example, let a differentiable d -submanifold M of \mathbb{R}^n be the graph of differentiable map $f : I^d \rightarrow \mathbb{R}^{n-d}$ at the vicinity of $p := (x_0, f(x_0)) \in M$, then $T_p M$ is the \mathbb{R} -linear span of the column vectors of $\begin{bmatrix} Id_d \\ J_{x_0} f \end{bmatrix}$, i.e. $T_p M := \{(x, (J_{x_0} f)x) \in \mathbb{R}^d \times \mathbb{R}^{n-d} \mid x \in \mathbb{R}^d\}$. Recall that the first order approximation of f at x_0 is defined by $f(x_0) + (J_{x_0} f)(x - x_0)$, i.e. the linear part of the Taylor expansion of f . The graph of the first order approximation is $p + T_p M$ (here $+$ is the Minkowski sum), i.e. the affine d -subspace of \mathbb{R}^n tangent to M at p . As usual, the normal space $N_p M$ is defined to be the orthogonal complement of $T_p M$.

Recall that for a twice differentiable d -submanifold M of \mathbb{R}^n , the second osculating space at $p \in M$ is defined to be $T_p^2 M := \text{span}_{\mathbb{R}} \left\{ \frac{\partial^2}{\partial x^i \partial x^j}, \frac{\partial}{\partial x^k} \right\}$ where x^1, \dots, x^d are local coordinates at the vicinity of p . An elementary example of the second osculating space is the osculating planes of a C^∞ regular curve in \mathbb{R}^3 . Also recall that, if $\exists p \in M$ s.t. $\dim T_p^2 M = n$, then M is substantial. This provides an practical criterion of substantialness.

For a C^2 submanifold M , as usual we say that $p \in M$ is a inflection point of M iff $p + T_p M$ is of high order tangency with M at p , i.e. at the vicinity of p , M coincides with the graph of a C^2 map with a non-Morse singularity at p .

1.5. Embedded Vector Bundles. For any integer $0 \leq k \leq n$ we denote by $\text{Gr}_k(n)$ the Grassmanian of k -subspaces in \mathbb{R}^n . We denote by $\tau_k(n) := \{(p, u) \in \text{Gr}_k(n) \times \mathbb{R}^n \mid u \in p\}$ then tautological bundle over $\text{Gr}_k(n)$, where the first projection π_1 gives the bundle map, and the second projection π_2 is the blow up.

Let X be a topological subspace of \mathbb{R}^n then a continuous map $\varphi : X \rightarrow \text{Gr}_k(n)$ pulls back an k -vector bundle over X with a canonical embedding into $\mathbb{R}^n \times \mathbb{R}^n$, by the following commutative diagram.

$$\begin{array}{ccccc}
 \mathbb{R}^n & \xleftarrow{Id_n} & \mathbb{R}^n & \xrightarrow{Id_n} & \mathbb{R}^n \\
 \uparrow & & \uparrow & & \uparrow \\
 0 \times Id_n & & & & \pi_2 \\
 \mathbb{R}^n \times \mathbb{R}^n & \xleftarrow{i} & \varphi^* \tau_k(n) & \xrightarrow{\tilde{\varphi}} & \tau_k(n) \\
 \downarrow & & \downarrow & & \downarrow \\
 Id_n \times 0 & & & & \pi_1 \\
 \mathbb{R}^n & \xleftarrow{i_X} & X & \xrightarrow{\varphi} & Gr_k(n)
 \end{array}$$

FIGURE 1.5.1

$\varphi^* \tau_k(n)$ is said to be the vector bundle defined by φ . If $k = 1$ then $Gr_1(n) = \mathbb{P}^{n-1}$ and $\varphi^* \tau_1(n)$ is called a line bundle.

In this paper we consider only embedded vector bundles pullbacked from tautological bundles, by abuse of notion we write vector bundles as abbreviation.

Let us recall several properties and examples of vector bundles.

If the base space $X = M$ is a topological d -submanifold of \mathbb{R}^n then $\varphi^* \tau_k(n)$ is a topological $(d+k)$ -submanifold of \mathbb{R}^{2n} . Moreover if M is C^r and φ is C^r then $\varphi^* \tau_k(n)$ is a C^r submanifold. An open cover of M simutanously serves as an atlas of M and trivalizes $\varphi^* \tau_k(n)$ exists and is said to be a trivalizing atlas, its elements are called trivalizing charts. Moreover, take any trivalizing chart $U \subseteq M$ we have a parametrization map $\mathbf{f} : \Omega \rightarrow \mathbb{R}^n$ and a matrix-valued function $A : \Omega \rightarrow \mathbb{R}^{n \times k}$ s.t. $\mathbf{f}(\Omega) = U$, $\text{Im } A(x) = \varphi(\mathbf{f}(x))$ and $F : \Omega \times \mathbb{R}^k \rightarrow E \subseteq \mathbb{R}^n \times \mathbb{R}^n$ defined by $F(x, \xi) \mapsto (\mathbf{f}(x), A(x)\xi)$ is the trivilization over U .

Let $f : Y \rightarrow X$ be a continuous map between two topological subspaces of \mathbb{R}^n and $E := \varphi^* \tau_k(n)$ be a k -vector bundle over X defined by continuous map $\varphi : X \rightarrow Gr_k(n)$, then f pulls back a k -vector bundle $f^* E = f^*(\varphi^* \tau_k(n)) = (\varphi \circ f)^* \tau_k(n) = \{(y, u) \mid u \in \varphi(f(y)), y \in Y\}$ over Y . In particular if $Y \stackrel{i}{\subseteq} X$ then $i^* E = \{(y, u) \mid u \in \varphi(y), y \in Y\} \subseteq E$.

For any differentiable submanifold M in \mathbb{R}^n we have the subset $TM := \{(p, u) \mid u \in T_p M, p \in M\} \subseteq \mathbb{R}^n \times \mathbb{R}^n$. Notice that if M is C^r with positive r then TM is the tangent bundle defined by C^{r-1} map $\varphi : p \rightarrow T_p M$. If M is differentiable but not C^1 then TM does not necessarily have a bundle structure. By abuse of notation in this case we still call it the tangent bundle of M .

The case for the normal bundle $NM := \{(p, u) \mid u \in N_p M, p \in M\}$ is analogous.

1.6. The Codiagonal Morphism. In the category of finite-dimensional \mathbb{R} -vector spaces the codiagonal morphism Δ_* is defined via the following commutative diagram as the dual of Δ .

FIGURE 1.6.1

As a map on Euclidean spaces, $\Delta_* : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^n$ is bi-linear and hence C^∞ . Take any subset E of $\mathbb{R}^n \times \mathbb{R}^n$, $\Delta_* E \subseteq \mathbb{R}^n$ is the continuous image under Δ_* . It possesses the following obvious properties:

- i). Take any subsets $A, B \subseteq \mathbb{R}^n \times \mathbb{R}^n$, we have $\Delta_*(A \cup B) = \Delta_* A \cup \Delta_* B$ and $\Delta_*(A \cap B) = \Delta_* A \cap \Delta_* B$. If $A \subseteq B$, then $\Delta_* A \subseteq \Delta_* B$.
- ii). Let E be a vector bundle defined by $\varphi : X \rightarrow \text{Gr}_k(n)$, then $\Delta_* E = \bigcup_{x \in X} (x + \varphi(x))$.

In particular, if M is a differentiable submanifold, then $\Delta_* TM = \bigcup_{p \in M} (p + T_p M)$ and

$$\Delta_* NM = \bigcup_{p \in M} (p + N_p M).$$

- iii). Take any differentiable submanifolds $M \subseteq \mathbb{R}^m$ and $N \subseteq \mathbb{R}^n$, we have $\Delta_* T(M \times N) = \Delta_* \{((p, q), (u, v)) \mid (u, v) \in T_p M \oplus T_q N, (p, q) \in M \times N\} = \Delta_* \{((p, q), (u, v)) \mid u \in T_p M, v \in T_q N, p \in M, q \in N\} = \{(p + u, q + v) \mid u \in T_p M, v \in T_q N, p \in M, q \in N\} = \Delta_* TM \times \Delta_* TN$.

Let E be a k -vector bundle over a topological subspace $X \subseteq \mathbb{R}^n$ then $\Delta_* E$ is the union of a family of k -affine subspaces of \mathbb{R}^n covers X . For example if X is a C^∞ regular curve in \mathbb{R}^3 and $E = TX$ is its tangent bundle, then $\Delta_* E$ is the tangent developable of X . However, as we will show later in this paper, if the assumption on smoothness is weakened then the structure of $\Delta_* E$ can be complicated. In geometric measure theory, it is important to study these objects from analytic point of view, since they are closely related to Kakeya's conjecture.

For instance, Cumberbatch, Keleti, and Zhang [2] studied the Hausdorff dimension of the union of tangent lines of a plane curve and in particular, they constructed a convex curve whose union of one-sided tangents has small Hausdorff dimension, these results were generalized to high dimensions in [1]. R.O. Davies [10] proved that any subset A of the plane can be covered by a collection of affine lines such that the union of lines has the same Lebesgue measure as A , and in [3] Esa Järvenpää et al. studied the non-empty interior of continuously parametrized Besicovitch sets. Also, in [6], Kornélia Héra, Keleti Tamás and András Máthé estimated the Hausdorff dimension of union of family of affine spaces.

In this paper we mainly discuss the subcase that $X = M$ is a (at least) differentiable d -submanifold of \mathbb{R}^n and E is a k -vector bundle or $E = TM, NM$. Under this assumption, E can be regarded as a parametrized family of k -affine subspaces with d independent parameters, hence we expect $\Delta_* E$ to have Hausdorff dimension $k + d$ when $k + d \leq n$, and have positive n -dimensional Lebesgue measure when $k + d > n$. In this case we (informally) say that E attains its expected

size. We shall study in this paper the conditions for normal and tangent bundles, and then general k -vector bundles and line bundles, to attain expected size.

1.7. Section Transform for Differentiable Mappings. We introduce tools for studying tangent bundle of graph of a differentiable map.

Definition 1.7.1. For any differentiable map $f : I^d \rightarrow \mathbb{R}^{n-d}$, we define the lifted section map of f by

$$\Phi_f : I^d \times \mathbb{R}^d \longrightarrow \mathbb{R}^d \times \mathbb{R}^{n-d} \\ (x, a) \longmapsto (a, f(x) + (J_x f)(a - x))$$

and for any $a \in \mathbb{R}^d$ define the section transform of f at a by

$$\phi_f^a : I^d \longrightarrow \mathbb{R}^{n-d} \\ x \longmapsto f(x) + (J_x f)(a - x)$$

The importance of the lifted section map is suggested by the following lemma.

Lemma 1.7.2. For any differentiable map $f : I^d \rightarrow \mathbb{R}^{n-d}$ we have $\Phi_f(I^d \times \mathbb{R}^d) = \Delta_* T\Gamma_f$.

Proof. Since $T\Gamma_f$ is parametrized globally by

$$I^d \times \mathbb{R}^d \longrightarrow \mathbb{R}^n \times \mathbb{R}^n \\ F : (x, \xi) \longmapsto \left((x, f(x)), \begin{bmatrix} \text{Id}_d \\ J_x f \end{bmatrix} \xi \right)$$

in particular $T\Gamma_f = F(I^d \times \mathbb{R}^d)$ and hence $\Delta_* T\Gamma_f = \Delta_* F(I^d \times \mathbb{R}^d)$. Since $\Delta_* F(x, \xi) = (x + \xi, f(x) + (J_x f)\xi) = (x + \xi, f(x) + (J_x f)((x + \xi) - x)) = \Phi_f(x, x + \xi)$ and $\begin{cases} x = x \\ a = x + \xi \end{cases}$ is a change of coordinates in $I^d \times \mathbb{R}^d$, we conclude that $\Phi_f(I^d \times \mathbb{R}^d) = \Delta_* F(I^d \times \mathbb{R}^d) = \Delta_* T\Gamma_f$. \blacksquare

In order to compute the lifted section map, we will use several properties of the section transform.

Lemma 1.7.3. For any $a \in \mathbb{R}^d$ and differentiable function $f, g : I^d \rightarrow \mathbb{R}^{n-d}$ we have:

- i). For any $A \in \text{End}(\mathbb{R}^{n-d})$, $\phi_{Af+g}^a = A\phi_f^a + \phi_g^a$.
- ii). For any affine map $\ell : I^k \rightarrow I^d$, $\phi_{f \circ \ell}^{\ell(a)} = \phi_f^{\ell(a)} \circ \ell$.

Proof.

- i). $\forall x \in I^d$, $\phi_{Af+g}^a(x) = Af(x) + g(x) + (J_x(Af+g))(a-x) = A(f(x) + (J_x f)(a-x)) + (g(x) + (J_x g)(a-x)) = A\phi_f^a + \phi_g^a$.
- ii). Denote $\ell(0) = \xi$ then $\exists A \in \text{End}(\mathbb{R}^{n-d})$ s.t $\ell = \xi + A$. $\forall x \in I^d$, $\phi_{f \circ \ell}^{\ell(a)}(x) = f \circ \ell(x) + J_x(f \circ \ell)(a-x) = f(\ell(x)) + (J_{\ell(x)} f \circ J_x \ell)(a-x) = f(\ell(x)) + (J_{\ell(x)} f)A(a-x) = f(\ell(x)) + (J_{\ell(x)} f)(\ell(a) - \ell(x)) = \phi_f^{\ell(a)} \circ \ell(x)$. \blacksquare

Before we close this section, we present a weak version of implicit function theorem proved by using Brouwer's fixed point theorem instead of the Banach fixed point theorem. The corollary of this theorem is powerful when applied to the lifted section maps.

In the following proof, as usual, for any bounded operator A we denote by $\|A\|_{op}$ its operator norm and by A_L^{-1} its left inverse (if exists).

Theorem 1.7.4. *Let $0 \leq n \leq m$ be integers, Ω be an open subset of \mathbb{R}^m and $h : \Omega \rightarrow \mathbb{R}^n$ be a continuous map differentiable at $x_0 \in \Omega$ s.t. $d_{x_0}h$ has full rank, then $\exists \varepsilon > 0$ s.t. $\forall y \in \bar{B}_{\lambda\varepsilon}^n(y_0)$, $h^{-1}(\{y\}) \cap \bar{B}_\varepsilon^m(x_0) \neq \emptyset$, and $\forall x \in h^{-1}(\{y\}) \cap \bar{B}_\varepsilon^m(x_0)$, $\lambda \|x - x_0\| \leq \|y - y_0\| \leq (\|d_{x_0}h\|_{op} + \lambda) \|x - x_0\|$,*

where $y_0 := h(x_0)$ and $\lambda := \frac{1}{2 \left\| (d_{x_0}h)_L^{-1} \right\|_{op}}$.

Proof. By the definition of derivative \exists sufficiently small $\varepsilon > 0$, s.t. $\bar{B}_\varepsilon^m(x_0) \subseteq \Omega$ and $\forall x \in \bar{B}_\varepsilon^m(x_0)$, $\|(h(x) - h(x_0)) - (d_{x_0}h)(x - x_0)\| < \lambda \|x - x_0\|$. For any $y \in \mathbb{R}^n$ define $\Psi_y : \Omega \rightarrow \mathbb{R}^n$ by $\Psi_y := x - (d_{x_0}h)_L^{-1}(h(x) - y)$, then Ψ_y is continuous, and $\Psi_y(x) = x$ iff $(d_{x_0}h)_L^{-1}(h(x) - y) = 0$, i.e. $h(x) = y$. Moreover we have

$$\begin{aligned} x_0 - \Psi_y(x) &= x_0 - x + (d_{x_0}h)_L^{-1}(h(x) - y) \\ &= (x_0 - x) + (d_{x_0}h)_L^{-1}(h(x) - h(x_0)) + (d_{x_0}h)_L^{-1}(y_0 - y) \\ &= (d_{x_0}h)_L^{-1}((h(x) - h(x_0)) - (d_{x_0}h)(x - x_0)) + (d_{x_0}h)_L^{-1}(y_0 - y) \end{aligned}$$

Fix $y \in \bar{B}_{\lambda\varepsilon}^n(y_0)$. For any $x \in \bar{B}_\varepsilon^m(x_0)$, we have

$$\begin{aligned} \|x_0 - \Psi_y(x)\| &\leq \left\| (d_{x_0}h)_L^{-1} \right\|_{op} \|(h(x) - h(x_0)) - (d_{x_0}h)(x - x_0)\| + \left\| (d_{x_0}h)_L^{-1} \right\|_{op} \|y - y_0\| \\ &\leq \frac{1}{2\lambda} \cdot \lambda \|x - x_0\| + \frac{1}{2\lambda} \|y - y_0\| \\ (*) \quad &\leq \frac{1}{2} \left(\|x - x_0\| + \frac{1}{\lambda} \|y - y_0\| \right) \\ &\leq \frac{1}{2} \left(\varepsilon + \frac{1}{\lambda} \cdot \lambda\varepsilon \right) \\ &= \varepsilon \end{aligned}$$

i.e. $\Psi_y(x) \in \bar{B}_\varepsilon^m(x_0)$. Since $\Psi_y(x)$ is continuous on $\bar{B}_\varepsilon^m(x_0)$ and $\Psi_y(\bar{B}_\varepsilon^m(x_0)) \subseteq \bar{B}_\varepsilon^m(x_0)$, by Brouwer's fixed point theorem $\exists x_* \in \bar{B}_\varepsilon^m(x_0)$ s.t. $\Psi_y(x_*) = x_*$, i.e. $h(x_*) = y$. Therefore $x_* \in h^{-1}(\{y\}) \cap \bar{B}_\varepsilon^m(x_0)$ and hence $h^{-1}(\{y\}) \cap \bar{B}_\varepsilon^m(x_0) \neq \emptyset$.

Take any $x \in h^{-1}(\{y\}) \cap \bar{B}_\varepsilon^m(x_0)$, then $h(x) = y$ and hence $\Psi_y(x) = x$. Therefore by the estimation (*), we have $\|x - x_0\| = \|x_0 - \Psi_y(x)\| \leq \frac{1}{2} \left(\|x - x_0\| + \frac{1}{\lambda} \|y - y_0\| \right)$, and hence

$\|x - x_0\| \leq \frac{1}{\lambda} \|y - y_0\|$, i.e. $\lambda \|x - x_0\| \leq \|y - y_0\|$. Moreover, we have

$$\begin{aligned} \|y - y_0\| &= \|h(x) - h(x_0)\| \\ &\leq \|h(x) - h(x_0) - (d_{x_0}h)(x - x_0)\| + \|(d_{x_0}h)(x - x_0)\| \\ &\leq \lambda \|x - x_0\| + \|d_{x_0}h\|_{op} \|x - x_0\| \\ &= \left(\|d_{x_0}h\|_{op} + \lambda \right) \|x - x_0\| \end{aligned}$$

In summary $\lambda \|x - x_0\| \leq \|y - y_0\| \leq (\|d_{x_0}h\|_{op} + \lambda) \|x - x_0\|$.

This concludes the proof. ■

Remark 1.7.5. In [7] this theorem is proved for $m = n$ and $\Omega = \mathbb{R}^n$. The proof is essentially the same. Notice that the classical implicit function theorem holds also for Banach manifolds. However,

since balls in infinite dimensional spaces are not compact in the norm topology, Brouwer's fixed point theorem does not hold, and hence this weak form of the implicit function theorem cannot be generalized directly to general Banach spaces or Hilbert spaces.

Corollary 1.7.6. *Let $0 \leq n \leq m$ be integer, Ω be an open subset of \mathbb{R}^m and $h : \Omega \rightarrow \mathbb{R}^n$ be a continuous map. If $\exists x_0 \in \Omega$ s.t. h is differentiable at x_0 and $d_{x_0}h$ has full rank, then $\text{int}(h(\Omega)) \neq \emptyset$.*

Proof. Denote $y_0 := h(x_0)$ then by Theorem 1.7.4 $\exists \delta > 0$ s.t. $\forall y \in \bar{B}_\delta^n(y_0)$ the fiber $h^{-1}(\{y\}) \neq \emptyset$. Therefore $h(\Omega) \supseteq \bar{B}_\delta^n(y_0)$ has non-empty interior. \blacksquare

1.8. Universal Measurability and Analyticity. Before discussing Lebesgue measure and Hausdorff dimension of union of tangents and normals or codiagonal of vector bundles over submanifolds we shall prove their measurability. Using the section transforms we will show that these objects are analytic sets (aka. Suslin sets) in \mathbb{R}^n , and hence universally measurable. (for basic properties of analytic sets, see e.g. [8])

Firstly we point out that this property clearly holds for codiagonal of vector bundle over submanifolds. For completeness we give a proof.

Proposition 1.8.1. *Let X be a topological submanifold (with boundary) of $\mathbb{R}^n \times \mathbb{R}^n$, then Δ_*X is analytic and hence universally measurable.*

Proof. By the Lindelöf property of second countable spaces, X admits a countable atlas $\{U_k\}_{k \in \mathbb{N}^*}$. Since for any $i \in \mathbb{N}^*$, U_k is homeomorphic to a open disk, we have that U_k is analytic. Therefore $X = \bigcup_{k \in \mathbb{N}^*} U_k$ is an analytic set. Since Δ_* is continuous, we have that Δ_*X is analytic and hence universally measurable. \blacksquare

Corollary 1.8.2. *Let M be a topological submanifold (with boundary) of \mathbb{R}^n and E be a vector bundle over M , then Δ_*E is analytic and hence universally measurable.*

Now we shall prove the same assertion for union of tangents (and normals).

Lemma 1.8.3. *For any differentiable map $f : I^d \rightarrow \mathbb{R}^{n-d}$ we have that Δ_*TT_f is analytic and hence universally measurable.*

Proof. Denote by e_1, \dots, e_d the standard orthonormal basis of $\mathbb{R}^d \supseteq I^d$ and define $\rho_i : I^d \rightarrow \mathbb{R}_+$ by $\rho_i(x) := \frac{1}{4} (|\pi - x^i| + |\pi + x^i| - ||\pi - x^i| - |\pi + x^i||)$ then by construction $\forall t \in [0, 1], \forall x \in I^d$ we have $x + t\rho_i(x)e_i \in I^d$. For any $k \in \mathbb{N}^*, i = 1, \dots, d$ and $j = 1, \dots, n - d$, define $T_{ij}^{(k)} : I^d \rightarrow \mathbb{R}^{n-d}$ by $T_{ij}^{(k)}(x) := \frac{f^j(x + \frac{1}{k}\rho_i(x)e_i) - f^j(x)}{\rho_i(x)/k}$, then $T_{ij}^{(k)}$ is continuous and by the definition of the

directional derivatives $\forall x \in I^d$ we have $\lim_{k \rightarrow \infty} T_{ij}^{(k)}(x) = \frac{\partial f^j}{\partial x^i}(x)$. Therefore the matrix-valued function $(T_{ij}^{(k)}) : I^d \rightarrow \mathbb{R}^{(n-d) \times d}$ is continuous and $\forall x \in I^d$ we have $\lim_{k \rightarrow \infty} (T_{ij}^{(k)}(x)) = J_x f$.

Define $\Phi_f^{(k)} : I^d \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^{n-d}$ by $\Phi_f^{(k)}(x, a) := (a, f(x) + (T_{ij}^{(k)}(x))(a - x))$, then clearly $\Phi_f^{(k)}$ is continuous, and in particular is Borel measurable. Since $\forall (x, a) \in I^d \times \mathbb{R}^d, \lim_{k \rightarrow \infty} \Phi_f^{(k)}(x, a) = (a, f(x) + \lim_{k \rightarrow \infty} (T_{ij}^{(k)}(x))(a - x)) = (a, f(x) + (J_x f)(a - x)) = \Phi_f(x, a)$, i.e. Φ_f is the pointwise

limit of $\left\{ \Phi_f^{(k)} \right\}_{k \in \mathbb{N}^*}$, we conclude that Φ_f is Borel. Therefore Γ_{Φ_f} is a Borel set. Since $\Phi_f(I^d \times \mathbb{R}^d)$ is the projection image of Γ_{Φ_f} on to the codomain of Φ_f , we obtain that $\Phi_f(I^d \times \mathbb{R}^d)$ is analytic.

This proves that $\Delta_* T\Gamma_f = \Phi_f(I^d \times \mathbb{R}^d)$ is analytic and hence universally measurable. \blacksquare

Proposition 1.8.4. *Let M be a differentiable submanifold then $\Delta_* TM$ is analytic and hence universally measurable.*

Proof. By the definition of differentiable submanifolds, and by Corollary 1.3.6, \exists atlas $\{U_k\}_{k \in \Lambda}$ of M s.t. $U_k = \Gamma_{f_k}$ where up to a rigid motion and homothety $f_k : I^d \rightarrow \mathbb{R}^{n-d}$ is differentiable. Moreover, by the Lindelöf property wlog we assume that $\Lambda \equiv \mathbb{N}^*$ is countable. Since $\Delta_* TM = \Delta_* T\left(\bigcup_{k \in \mathbb{N}^*} U_k\right) = \Delta_*\left(\bigcup_{k \in \mathbb{N}^*} TU_k\right) = \bigcup_{k \in \mathbb{N}^*} (\Delta_* TU_k)$, and by Lemma 1.8.3, $\forall k \in \mathbb{N}^*$, $\Delta_* TU_k = \Delta_* T\Gamma_{f_k}$ is analytic, we conclude that $\Delta_* TM$ is analytic, and hence universally measurable. \blacksquare

Lemma 1.8.5. *For any differentiable map $f : I^d \rightarrow \mathbb{R}^{n-d}$ we have that $\Delta_* N\Gamma_f$ is analytic and hence universally measurable.*

Proof. Use the same notations as in Lemma 1.8.3.

Take any $x_0 \in I^d$ and denote $p := (x_0, f(x_0))$ then it is clear that $p + N_p \Gamma_f = \{(x, y) \in \mathbb{R}^d \times \mathbb{R}^{n-d} \mid (x - x_0) + (J_{x_0} f)(y - f(x_0)) = 0\} = \{(x, y) \in \mathbb{R}^d \times \mathbb{R}^{n-d} \mid x = x_0 + (J_{x_0} f)(f(x_0) - y)\} = \{(x_0 + (J_{x_0} f)(f(x_0) - y), y) \mid y \in \mathbb{R}^{n-d}\}$. Therefore define $\Psi_f : I^d \times \mathbb{R}^{n-d} \rightarrow \mathbb{R}^d \times \mathbb{R}^{n-d}$ by $\Psi_f(x, b) = (x + (J_x f)(f(x) - b), b)$ then $\Psi_f(I^d \times \mathbb{R}^{n-d}) = \bigcup_{p \in \Gamma_f} (p + N_p \Gamma_f) = \Delta_* NM$.

For any $k \in \mathbb{N}^*$ define $\Psi_f^{(k)} : I^d \times \mathbb{R}^{n-d} \rightarrow \mathbb{R}^d \times \mathbb{R}^{n-d}$ by $\Psi_f^{(k)}(x, b) := \left(x + \left(T_{ij}^{(k)}(x)\right)(f(x) - b), b\right)$ where $\left(T_{ij}^{(k)}\right)$ is the approximation of Jacobian defined in Lemma 1.8.3, then similarly we have that $\left\{ \Psi_f^{(k)} \right\}_{k \in \mathbb{N}^*}$ is a sequence of Borel function with pointwise limit Ψ_f and hence Ψ_f is Borel. Therefore Γ_{Ψ_f} is a Borel set, and $\Psi_f(I^d \times \mathbb{R}^{n-d})$ is an analytic set.

This proves that $\Delta_* N\Gamma_f = \Psi_f(I^d \times \mathbb{R}^{n-d})$ is analytic and hence universally measurable. \blacksquare

Proposition 1.8.6. *Let M be a differentiable submanifold then $\Delta_* NM$ is analytic and hence universally measurable.*

Proof. Apply Lemma 1.8.5, the proof is the same as that of Proposition 1.8.4. \blacksquare

Now we are prepared to study the measure theoretical size of union of tangents and normals, and codiagonal of vector bundles over submanifolds.

2. SIZE OF UNION OF NORMALS AND TANGENTS

2.1. Normal Bundles. We first study the size of normal bundles.

Take the tubular neighborhood theorem into account, one may expect that the normal bundle over a smooth submanifold always contains an open subset. Actually more is true: using the square distance function, we will show that this assertion holds for all differentiable submanifolds.

Definition 2.1.1. Take any subset $X \subseteq \mathbb{R}^n$ and point $q \in \mathbb{R}^n$, define the square distance $S_X^q : X \rightarrow \mathbb{R}$ by $S_X^q(p) := \|p - q\|^2$.

Lemma 2.1.2. *For any differentiable d -submanifold M of \mathbb{R}^n , $p \in M$ is a critical point of S_M^q iff $q - p \in N_p M$.*

Proof. Let $\mathbf{r} : B_\varepsilon^d \rightarrow \mathbb{R}^n$ be a parametrization map of M at the vicinity of $p \equiv \mathbf{r}(0)$ then $q \in N_p M$ iff $\forall i \in \{1, \dots, d\} \left\langle q - \mathbf{r}(0), \frac{\partial \mathbf{r}}{\partial x_i}(0) \right\rangle = 0$, i.e. $\frac{\partial}{\partial x_i} S_M^q(\mathbf{r}(0)) = 2 \left\langle q - \mathbf{r}(0), \frac{\partial \mathbf{r}}{\partial x_i}(0) \right\rangle = 0$, i.e. S_M^q is critical at $\mathbf{r}(0) = p$. \blacksquare

Corollary 2.1.3. *Let M be a closed differentiable submanifold of \mathbb{R}^n , then $\Delta_* N M = \mathbb{R}^n$.*

Proof. Take any $q \in \mathbb{R}^n$, since q and M are compact, S_M^q attains a minima $S_M^q(p_0)$, in particular S_M^q is critical at p_0 . By Lemma 2.1.2 $q \in p_0 + N_{p_0} M \subseteq \Delta_* N M$. \blacksquare

Corollary 2.1.4. *Let M be a differentiable d -submanifold of \mathbb{R}^n , then \exists open neighbourhood $\nu(M)$ in \mathbb{R}^n s.t. $M \subseteq \nu(M) \subseteq \Delta_* N M$. In particular, $\text{int}(\Delta_* N M) \neq \emptyset$.*

Proof. Take any $p \in M$, for a sufficiently small $r > 0$, we have $B := B_{2r}^n(p) \cap M$ is homeomorphic to B_{2r}^d , and $\bar{B} \setminus B \subseteq \bar{B}_{2r}^n(p) \setminus B_{2r}^n(p) = \partial B_{2r}^n(p)$.

Take any $q \in B_r^n(p)$, then S_B^q attains a minima $S_B^q(p_0)$. Since $d(q, \bar{B} \setminus B) \geq d(q, \partial B_{2r}^n(p)) > r > d(q, p)$, we have that $p_0 \in B$. Therefore p_0 is a critical point of $S_B^q = S_B^q|_B$. Since B is a differentiable submanifold of \mathbb{R}^n , by Lemma 2.1.2 $q \in p_0 + N_{p_0} B \subseteq \Delta_* N M$. Therefore $B_r^n(p) \subseteq \Delta_* N M$.

This proves that $\forall p \in M, p \in \text{int}(\Delta_* N M)$. Therefore the required neighborhood exists. \blacksquare

2.2. Tangent Bundles. For the union of tangents, the situation is more complicated.

We start by estimating the Hausdorff dimension.

Firstly, for any differentiable d -submanifold M of \mathbb{R}^n , since $M \subseteq \Delta_* T M$, we have the lower bound $d = \dim M \leq \dim_{\mathcal{H}} M \leq \dim_{\mathcal{H}} \Delta_* T M$. By taking M to be an affine subspace, one can show that this inequality is sharp.

Moreover, under several natural conditions, we have the following upper bounds:

Proposition 2.2.1. *Let $\Pi \subseteq \mathbb{R}^n$ be a d -affine subspace and M a differentiable submanifold of \mathbb{R}^n , then $M \subseteq \Pi$ iff $\Delta_* T M \subseteq \Pi$. In particular in this case we have $\dim_{\mathcal{H}} \Delta_* T M \leq d$.*

Proof. Obvious. \blacksquare

Proposition 2.2.2. *If M is a Lipschitz-continuously differentiable d -submanifold, then $\dim_{\mathcal{H}} \Delta_* T M \leq 2d$.*

Proof. Cover M by a countable atlas $\{U_k\}_{k \in \mathbb{N}}$ s.t. $U_k = \Gamma_{f_k}$ where up to rigid motion and homothety $f_k : I^d \rightarrow \mathbb{R}^{n-d}$ is differentiable and df_k is locally Lipschitz, then the lifted section map $\Phi_{f_k}(x, a) = (a, f_k(x) + (J_x f_k)(a - x))$ is locally Lipschitz, and hence $\dim_{\mathcal{H}} \Phi_{f_k}(I^d \times \mathbb{R}^d) \leq \dim_{\mathcal{H}}(I^d \times \mathbb{R}^d) = 2d$. Since $\Phi_{f_k}(I^d \times \mathbb{R}^d) = \Delta_* T U_k$ and $\Delta_* T M = \bigcup_{k \in \mathbb{N}} (\Delta_* T U_k)$, we have that

$$\dim_{\mathcal{H}} \Delta_* T M = \dim_{\mathcal{H}} \left(\bigcup_{k \in \mathbb{N}} \Delta_* T U_k \right) = \sup_{k \in \mathbb{N}} \dim_{\mathcal{H}} \Delta_* T U_k \leq 2d. \quad \blacksquare$$

Corollary 2.2.3. *If M is a C^2 d -submanifold, then $\dim_{\mathcal{H}} \Delta_* T M \leq 2d$.*

The following example shows that the inequalities in Proposition 2.2.2 and Corollary 2.2.3 are sharp.

Proposition 2.2.4. *For any $d \leq n \in \mathbb{N}^*$, $\exists C^\infty$ d -submanifold M of \mathbb{R}^n s.t. $\mathcal{L}^{2d}(\Delta_* T M) = +\infty$ or $\Delta_* T M = \mathbb{R}^n$.*

Proof. Identify $\mathbb{C}^1 \equiv \mathbb{R}^2$. Define $\gamma_1 := \left\{ 6e^{it} \mid t \in \left[\frac{\pi}{2}, \frac{3\pi}{2} \right] \right\}$, $\gamma_2 := \left\{ -3i + 3e^{it} \mid t \in \left[-\frac{\pi}{2}, \frac{\pi}{2} \right] \right\}$, $\gamma_3 := \left\{ 2i + 2e^{it} \mid t \in \left[\frac{\pi}{2}, \frac{3\pi}{2} \right] \right\}$, $\gamma_4 := \left\{ 5i + e^{it} \mid t \in \left[-\frac{\pi}{2}, \frac{\pi}{2} \right] \right\}$, then $\gamma := \bigcup_{k=1}^4 \gamma_k$ glues to a closed C^∞ regular curve in \mathbb{R}^2 .

It is easy to show that $\Delta_* T\gamma_1 = \mathbb{C}^1 \setminus (\{|z| < 1\} \cup \{\operatorname{Re} z \geq 0, |\operatorname{Im} z| \leq 1\})$ and mutatis mutandis for $\gamma_2, \gamma_3, \gamma_4$, then it is clear that $\Delta_* T\gamma = \Delta_* \left(\bigcup_{i=1}^4 T\gamma_i \right) = \bigcup_{i=1}^4 \Delta_* T\gamma_i = \mathbb{C}^1 \equiv \mathbb{R}^2$.

Consider the following two cases:

Case 1: $d < \frac{n}{2}$. Define $M := \underbrace{\gamma \times \cdots \times \gamma}_d \subseteq \underbrace{\mathbb{R}^2 \times \cdots \times \mathbb{R}^2}_d = \mathbb{R}^{2d} \hookrightarrow \mathbb{R}^n$, then M is a $C^\infty d$ -submanifold of \mathbb{R}^n . Since $\Delta_* TM = \underbrace{(\Delta_* T\gamma) \times \cdots \times (\Delta_* T\gamma)}_d = \underbrace{\mathbb{R}^2 \times \cdots \times \mathbb{R}^2}_d = \mathbb{R}^{2d}$, we have

$$\mathcal{L}^{2d}(\Delta_* TM) = +\infty.$$

Case 2: $d \geq \frac{n}{2}$. Define $M := \underbrace{\gamma \times \cdots \times \gamma}_{n-d} \times \mathbb{R}^{2d-n}$, then M is a C^∞ submanifold of \mathbb{R}^n with $\dim M = n - d + 2d - n = d$, and $\Delta_* TM = \underbrace{\mathbb{R}^2 \times \cdots \times \mathbb{R}^2}_{n-d} \times \mathbb{R}^{2d-n} = \mathbb{R}^{2(n-d)+2d-n} = \mathbb{R}^n$. \blacksquare

The following example shows that the Lipschitz condition in Proposition 2.2.2 is necessary.

Proposition 2.2.5. *For any $d \leq n \in \mathbb{N}^*$, $\exists C^1$ d -submanifold M of \mathbb{R}^n , s.t. $\Delta_* TM = \mathbb{R}^n$.*

Proof. Recall that $\forall m \in \mathbb{N}$ we have \mathbb{R}^m is a σ -Peano space, i.e. \exists continuous surjection $\varphi_m : \mathbb{R} \rightarrow \mathbb{R}^m$. Moreover, φ_m can be chosen to be a self-similar curve. Denote $\varphi := \varphi_{n-d+1}$ and consider the following Cauchy Problem:

$$(*) \quad f(t) + f'(t) = \varphi(t)$$

with initial condition $f(0) = 0$.

By Picard's existence theorem, $\exists \varepsilon > 0$ and differentiable function $\alpha :]-\varepsilon, \varepsilon[\rightarrow \mathbb{R}^{n-d+1}$ s.t. $\alpha(t) + \alpha'(t) = \varphi(t)$ and $\alpha(0) = 0$. Since $\alpha' = \varphi|_{]-\varepsilon, \varepsilon[} - \alpha$ is continuous, we have that α is C^1 .

Provided that $\alpha' \equiv 0$, then $\alpha \equiv \text{Constant}$ and hence $\varphi|_{]-\varepsilon, \varepsilon[} = \alpha + \alpha' = \text{Constant} + 0 \equiv \text{Constant}$, contracts the self-similarity of φ . Therefore $\exists t_0 \in]-\varepsilon, \varepsilon[$ s.t. $\alpha'(t_0) \neq 0$, and by the continuity of α' , \exists open neighborhood U of t_0 s.t. $\alpha'|_U \neq 0$. Therefore $\gamma := \alpha|_U$ is a C^1 regular curve in \mathbb{R}^{n-d+1} .

It is clear that $\forall t \in U$, $\varphi(t) = \alpha(t) + \alpha'(t) \in \Delta_* T\gamma$, i.e. $\varphi(U) \subseteq \Delta_* T\gamma$. By the self-similarity of φ , we have that $\varphi(U) = \varphi(\mathbb{R}) = \mathbb{R}^{n-d+1}$. This proves that $\Delta_* T\gamma = \mathbb{R}^{n-d+1}$.

Define $M := \gamma \times \mathbb{R}^{d-1} \hookrightarrow \mathbb{R}^{n-d+1} \times \mathbb{R}^{d-1} = \mathbb{R}^n$, then M is a C^1 d -submanifold of \mathbb{R}^n , and $\Delta_* TM = (\Delta_* T\gamma) \times (\Delta_* T\mathbb{R}^{d-1}) = \mathbb{R}^{n-d+1} \times \mathbb{R}^{d-1} = \mathbb{R}^n$. \blacksquare

Remark 2.2.6. The phenomenon in Proposition 2.2.5 is anti-intuitive. It shows that tangent lines of a C^1 regular curve can fill up the ambient space \mathbb{R}^n , and its tangent bundle is a 2-dimensional surface embedded in $\mathbb{R}^n \times \mathbb{R}^n$ with n -dimensional codiagonal.

From the previous discussion we have seen that union of tangents of various submanifolds can be very different in size. Take a differentiable submanifold M we shall provide a sufficient condition for $\text{int}(\Delta_* TM) \neq \emptyset$. By Proposition 2.2.1 and Corollary 2.2.3 M should be substantial and $\dim M \geq \frac{n}{2}$, but the following example shows that these two conditions are not enough.

Proposition 2.2.7. *Let $g : I \rightarrow \mathbb{R}^4$ be a substantial C^3 regular curve with positive curvature then its one-sided tangent developable Σ_+ is a substantial C^2 regular surface in \mathbb{R}^4 s.t. $\mathcal{L}^4(\Delta_*T\Sigma_+) = 0$.*

Proof. By Proposition 1.2.1 Σ_+ is a substantial C^2 regular surface in \mathbb{R}^4 .

Since Σ_+ is parametrized by $\mathbf{x}(u, v) = g(u) + vg'(u)$ and $\frac{\partial \mathbf{x}}{\partial u}(u, v) = g'(u) + vg''(u)$, $\frac{\partial \mathbf{x}}{\partial v}(u, v) = g'(u)$, for any $p := \mathbf{x}(u, v) \in \Sigma_+$ we have $p + T_p\Sigma_+ = \left\{ \mathbf{x}(u, v) + \lambda \frac{\partial \mathbf{x}}{\partial u}(u, v) + \mu \frac{\partial \mathbf{x}}{\partial v}(u, v) \mid (\lambda, \mu) \in \mathbb{R}^2 \right\} = \left\{ g(u) + (\lambda + \mu)g'(u) + \lambda vg''(u) \mid (\lambda, \mu) \in \mathbb{R}^2 \right\}$. Define C^1 function $f : \mathbb{R}^3 \rightarrow \mathbb{R}^4$ by $f(x, y, u) := g(u) + xg'(u) + yg''(u)$, then $f(\mathbb{R}^3) \supseteq \bigcup_{p \in \Sigma_+} (p + T_p\Sigma_+) = \Delta_*T\Sigma_+$. Since f is C^1 , by Sard's lemma we have $\mathcal{L}^4(f(\mathbb{R}^3)) = 0$, and hence $\mathcal{L}^4(\Delta_*T\Sigma_+) = 0$. \blacksquare

By strengthening the condition we obtain the following theorems.

Theorem 2.2.8. *Let Ω be an open subset in \mathbb{R}^d and $f : \Omega \rightarrow \mathbb{R}^{n-1}$ be a C^1 map s.t. f is twice differentiable at $x_0 \in \Omega$ with $d_{x_0}^2 f$ non-degenerated, then $\text{int}(\Delta_*\Gamma_f) \neq \emptyset$.*

Proof. Wlog assume that $\Omega = I^d$ and $x_0 = 0$. It suffices to prove that $\text{int}(\Phi_f(I^d \times \mathbb{R}^d)) \neq \emptyset$.

For any $b \in \mathbb{R}^d$, it is clear that $f(x)$, $J_x f$ and hence $\Phi_f(x, a) = (a, f(x) + (J_x f)(a - x))$ are continuous and differentiable at $(0, b)$, and $\frac{\partial \Phi_f(x, a)}{\partial(x, a)} \Big|_{(0, b)} = \begin{bmatrix} 0 & (d_0^2 f) b \\ Id_d & d_0 f \end{bmatrix} = \begin{bmatrix} 0 & \left(b^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right) \\ Id_d & J_0 f \end{bmatrix}$.

By Corollary 1.7.6 it remains to proof that $\exists b_0 \in \mathbb{R}^d$ s.t. $\frac{\partial \Phi_f(x, a)}{\partial(x, a)} \Big|_{(0, b_0)}$ has full rank, i.e.

$\left(b_0^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right)$ has full rank.

Since by assumption $d_0^2 f$ is non-degenerated, there exists $b_0 \in \mathbb{R}^d$ s.t. the contraction $\left(b_0^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right)$ has full rank.

This concludes the proof. \blacksquare

Theorem 2.2.9. *Let M be a twice differentiable d -submanifold of \mathbb{R}^n s.t. $d \geq \frac{n}{2}$ and $\exists p \in M$ s.t. $\dim T_p^2 M = n$, then $\text{int}(\Delta_*TM) \neq \emptyset$.*

Proof. Wlog assume that $p = 0$.

By assumption \exists local chart $U \subseteq M$, s.t. $U = \Gamma_f$ where up to rigid motion and homothety $f : I^d \rightarrow \mathbb{R}^{n-d}$ is twice differentiable and $f(0) = 0$. Since $\Delta_*TM \supseteq \Delta_*TU = \Phi_f(I^d \times \mathbb{R}^d)$, it suffices to prove that $\text{int}(\Phi_f(I^d \times \mathbb{R}^d)) \neq \emptyset$.

Since for any $b \in \mathbb{R}^d$, $f(x)$, $J_x f$, and hence $\Phi_f(x, a) = (a, f(x) + (J_x f)(a - x))$ are continuous and differentiable at $(0, b)$, and moreover $\frac{\partial \Phi_f(x, a)}{\partial(x, a)} \Big|_{(0, b)} = \begin{bmatrix} 0 & (d_0^2 f) b \\ Id_d & d_0 f \end{bmatrix} = \begin{bmatrix} 0 & \left(b^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right) \\ Id_d & J_0 f \end{bmatrix}$,

by Corollary 1.7.6 it remains to proof that $\exists b_0 \in \mathbb{R}^d$ s.t. $\frac{\partial \Phi_f(x, a)}{\partial(x, a)} \Big|_{(0, b_0)}$ has full rank, i.e.

$\left(b_0^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right)$ has full rank.

Since by assumption $\left\{ \left[\begin{array}{ccc|c} \left(\frac{\partial f^1(0)}{\partial x^i \partial x^j} \right) & \cdots & \left(\frac{\partial f^{n-d}(0)}{\partial x^i \partial x^j} \right) & J_0 f \\ 0 & \cdots & 0 & Id_d \end{array} \right] \xi \mid \xi \in \mathbb{R}^{(n-d+1)d} \right\} = T_p^2 M = \mathbb{R}^n$, we have that $\left[\left(\frac{\partial f^1(0)}{\partial x^i \partial x^j} \right) \cdots \left(\frac{\partial f^{n-d}(0)}{\partial x^i \partial x^j} \right) \right]$ has full rank. Therefore $\exists b_0 \in \mathbb{R}^d$ s.t. the contraction $\left(b_0^i \frac{\partial f^k(0)}{\partial x^i \partial x^j} \right)$ has full rank.

This concludes the proof. \blacksquare

3. FURTHER RESULTS FOR HYPERSURFACES

In section 1 we give a criterion for a C^1 submanifold M to have $\text{int}(\Delta_* TM) \neq \emptyset$. It turns out that if M is a hypersurface then this result can be significantly improved.

3.1. Tangent Bundle over Hypersurfaces. We start with the following important observation:

Lemma 3.1.1. *If $f : I^n \rightarrow \mathbb{R}$ is a differentiable function, then $\forall a \in I^n$, $\phi_f^a(I^n)$ is path-connected.*

Proof. Take any $x \in I^n \setminus \{a\}$, denote $\lambda := \frac{x+a}{2}$, then $(\lambda-a)t+\lambda, t \in [-1, 1]$ is a segment connecting a and x .

Define $h(t) := \phi_f^a((\lambda-a)t+\lambda), t \in [-1, 1]$, then $h(t) = f((\lambda-a)t+\lambda) + \nabla_{(\lambda-a)t+\lambda} f(a - ((\lambda-a)t+\lambda)^T) = f((\lambda-a)t+\lambda) - (t+1)(\nabla_{(\lambda-a)t+\lambda} f)(\lambda-a)$. Define $H(t) = 2 \int_0^t f((\lambda-a)s+\lambda) ds - (t+1)f((\lambda-a)t+\lambda)$, $t \in [-1, 1]$, then $\dot{H}(t) = 2f((\lambda-a)t+\lambda) - f((\lambda-a)t+\lambda) - (t+1) \frac{d((\lambda^i - a^i)t + \lambda^i)}{dt} \frac{\partial f((\lambda-a)t+\lambda)}{\partial((\lambda^i - a^i)t + \lambda^i)} = f((\lambda-a)t+\lambda) - (t+1)(\lambda^i - a^i) \frac{\partial f}{\partial x^i}((\lambda-a)t+\lambda) = f((\lambda-a)t+\lambda) - (t+1)(\nabla_{(\lambda-a)t+\lambda} f)(\lambda-a) = h(t)$. By Darboux theorem h has the intermediate value property. Since $h(-1) = \phi_f^a(-(\lambda-a)+\lambda) = \phi_f^a(a)$ and $h(1) = \phi_f^a((\lambda-a)+\lambda) = \phi_f^a\left(2\frac{x+a}{2} - a\right) = \phi_f^a(x)$, we obtain that $\phi_f^a(I^n) \supseteq \phi_f^a(\text{conv}\{a, x\}) = h([-1, 1]) \supseteq \text{conv}\{\phi_f^a(a), \phi_f^a(x)\}$.

Take any $x_1, x_2 \in I^n \setminus \{a\}$, since $\phi_f^a(I^n) \subseteq \mathbb{R}$, we have $\text{conv}\{\phi_f^a(x_1), \phi_f^a(x_2)\} \subseteq \text{conv}\{\phi_f^a(a), \phi_f^a(x_1)\} \cup \text{conv}\{\phi_f^a(a), \phi_f^a(x_2)\}$. Since $\phi_f^a(I^n) \supseteq \text{conv}\{\phi_f^a(a), \phi_f^a(x_k)\}, k = 1, 2$, we conclude that $\phi_f^a(I^n) \supseteq \text{conv}\{\phi_f^a(a), \phi_f^a(x_1)\} \cup \text{conv}\{\phi_f^a(a), \phi_f^a(x_2)\} \supseteq \text{conv}\{\phi_f^a(x_1), \phi_f^a(x_2)\}$.

This proves that ϕ_f^a is path-connected. \blacksquare

Here we give a straightforward application of Lemma 3.1.1 to real functions.

Corollary 3.1.2. *If $f : I \rightarrow \mathbb{R}$ is a nonlinear differentiable function, then for any $a \in I$, $\phi_f^a(I)$ is an interval with positive (or infinite) length.*

Proof. By Lemma 3.1.1, $\phi_f^a(I)$ is a connected subset of \mathbb{R} , i.e. a singleton or an interval with positive (or infinite) length. Therefore it suffices to show that $\forall a \in \mathbb{R}, \phi_f^a$ is not constant.

Provided that $\exists a \in \mathbb{R}$ s.t. $\phi_f^a \equiv b \in \mathbb{R}$, then we have $f(x) + (a-x)f'(x) = \phi_f^a(x) = b, \forall x \in \mathbb{R}$. Solve the ordinary differentiable equation $y + (a-x)y' = b$ by separating variables, we obtain $y + (a-x) \frac{dy}{dx} = b \iff \frac{dy}{y-b} = \frac{dx}{x-a} \iff \ln|y-b| = \ln|x-a| + C \iff y-b = k(x-a)$, i.e.

$y = k(x - a) + b$, where $C, k \in \mathbb{R}$ are constants. Therefore $\exists k \in \mathbb{R}$ s.t. $f(x) = k(x - a) + b$, contradicts the nonlinearity of f . Therefore $\forall a \in \mathbb{R}$, ϕ_f^a is not constant. \blacksquare

Now we are prepared to state the main theorems.

Proposition 3.1.3. *If $f : I^n \rightarrow \mathbb{R}$ is a nonlinear differentiable function, then $\text{int}(\Delta_* T\Gamma_f) \neq \emptyset$.*

Proof. By Corollary 1.3.9, \exists affine map $\ell : I \rightarrow I^n$ s.t. $f \circ \ell$ is nonlinear, moreover clearly $f \circ \ell$ is differentiable. Therefore by Corollary 3.1.2 $\exists s \in \mathbb{R}$ s.t. $\phi_{f \circ \ell}^s(I)$ is not a singleton. Since by Lemma 1.7.3 $\phi_f^{\ell(s)}(I^n) \supseteq \phi_f^{\ell(s)}(\ell(I)) = \phi_{f \circ \ell}^s(I)$ we have that $\phi_f^{\ell(s)}(I^n)$ is not a singleton.

Denote $a_0 := \ell(s)$, then $\exists x_1, x_2 \in I^n$, s.t. $\phi_f^{a_0}(x_1) < \phi_f^{a_0}(x_2)$. Since $\forall i = 1, 2$, $\phi_f^a(x_i) = f(x_i) + (J_{x_i} f)(a - x_i)$ is linear (and hence continuous) in a , denote $\delta := \frac{1}{2}(\phi_f^{a_0}(x_2) - \phi_f^{a_0}(x_1))$ then $\exists \varepsilon > 0$ s.t. $\forall a \in B_\varepsilon^n(a_0)$ we have $\left\| \phi_f^a(x_i) - \phi_f^{a_0}(x_i) \right\| < \delta$. Therefore denote $y_1 := \phi_f^{a_0}(x_1) + \delta$ and $y_2 := \phi_f^{a_0}(x_2) - \delta$ then $\forall a \in B_\varepsilon^n(a_0)$ we have $\phi_f^a(x_1) \leq y_1 < y_2 \leq \phi_f^a(x_2)$. By Lemma 3.1.1 $\forall a \in B_\varepsilon^n(a_0)$ we have $\phi_f^a(I^n) \supseteq]y_1, y_2[$. Therefore $\Delta_* T\Gamma_f = \Phi_f(I^n \times \mathbb{R}^n) \supseteq \Phi_f(I^n \times B_\varepsilon^n(a_0)) = \bigcup_{a \in B_\varepsilon^n(a_0)} \{a\} \times \varphi_f^a(I^n) \supseteq \bigcup_{a \in B_\varepsilon^n(a_0)} \{a\} \times]y_1, y_2[= B_\varepsilon^n(a_0) \times]y_1, y_2[$ where $B_\varepsilon^n(a_0) \times]y_1, y_2[$ is open in \mathbb{R}^{n+1} .

This proves that $\text{int}(\Delta_* T\Gamma_f) \neq \emptyset$. \blacksquare

Theorem 3.1.4. *If $M = M_1 \times \cdots \times M_m$ is a product of nonlinear differentiable hypersurfaces, then $\text{int}(\Delta_* TM) \neq \emptyset$.*

Proof. For any $i = 1, \dots, m$, by Corollary 1.3.6, \exists local chart $U_k \subseteq M_k$ s.t. $U_k = \Gamma_{f_k}$ where up to rigid motion and homothety $f_k : I^{n_k} \rightarrow \mathbb{R}$ is nonlinear and differentiable. By Proposition 3.1.3 \exists open subset W_k of \mathbb{R}^{n_k+1} s.t. $\Delta_* T\Gamma_{f_k} \supseteq W_k$. Therefore $\Delta_* TM = \Delta_* TM_1 \times \cdots \times \Delta_* TM_m \supseteq \Delta_* TU_1 \times \cdots \times \Delta_* TU_m = \Delta_* T\Gamma_{f_1} \times \cdots \times \Delta_* T\Gamma_{f_m} \supseteq W_1 \times \cdots \times W_m$, where $W_1 \times \cdots \times W_m$ is an open subset of the ambient space.

This proves that $\text{int}(\Delta_* TM) \neq \emptyset$. \blacksquare

Corollary 3.1.5. *If M is a nonlinear differentiable d -submanifold, then $\dim_{\mathcal{H}} \Delta_* TM \geq d + 1$.*

Proof. By Corollary 1.3.6 \exists local chart $U \subseteq M$ s.t. $U = \Gamma_f$ where up to rigid motion and homothety $f : I^d \rightarrow \mathbb{R}^{n-d}$ is nonlinear and differentiable. It suffices to prove that $\dim_{\mathcal{H}} \Phi_f(I^d \times \mathbb{R}^d) \geq d + 1$.

Since $f = (f^1, \dots, f^{n-d})$ is nonlinear and differentiable, there exists $k \in \{1, \dots, n-d\}$ s.t. $f^k : I^d \rightarrow \mathbb{R}$ is nonlinear and differentiable. By Proposition 3.1.3 we have $\dim_{\mathcal{H}} \Phi_{f^k}(I^d \times \mathbb{R}^d) = d + 1$. Denote by $\pi_k : \mathbb{R}^{n-d} \rightarrow \mathbb{R}$ the projection onto the k -th coordinate, then $\Phi_{f^k}(I^d \times \mathbb{R}^d) = \Phi_{\pi_k \circ f}(I^d \times \mathbb{R}^d) = (\pi_k \times Id_d) \circ \Phi_f(I^d \times \mathbb{R}^d)$. Since $\pi_k \times Id_d$ is Lipschitz, we have that $\dim_{\mathcal{H}} \Phi_f(I^d \times \mathbb{R}^d) \geq \dim_{\mathcal{H}} \Phi_{f^k}(I^d \times \mathbb{R}^d) = d + 1$.

This concludes the proof. \blacksquare

3.2. Hyperplane covering of a hypersurface. Moreover, if we assume more on the smoothness then we are able to obtain a much stronger result.

Theorem 3.2.1. *Let M be a nonlinear Lipschitz-continuously differentiable hypersurface in \mathbb{R}^{n+1} . If \mathcal{A} is a family of hyperplanes in \mathbb{R}^{n+1} s.t. $\cup \mathcal{A} \supseteq M$, then $\dim_{\mathcal{H}} \cup \mathcal{A} = n + 1$.*

Proof. By Corollary 1.3.6 \exists local chart $U \subseteq M$ s.t. $U = \Gamma_f$ where $f : \Omega \rightarrow \mathbb{R}$ is nonlinear and differentiable with Lipschitz-continuous gradient. Since f is nonlinear and continuous, by Proposition 1.3.11 up to rigid motion and homothety we have $I^n \subseteq \Omega$ and \exists non-empty open subset

B of I^{n-1} , s.t. $\forall x_0 \in B$ we have $f_{x_0}(t) := f(x_0^1, \dots, x_0^{n-1}, t)$, $t \in I$ is nonlinear. Since $\nabla_{(x,t)} f = \left(\frac{\partial f}{\partial x^1}, \dots, \frac{\partial f}{\partial x^{n-1}}, \frac{\partial f}{\partial t} \right)$ is Lipschitz we have that $\frac{\partial f}{\partial t}$ is Lipschitz. Since $f'_{x_0}(t) = \frac{\partial}{\partial t} f(x_0, t)$, we obtain that $f'_{x_0}(t)$ is Lipschitz. Therefore $f'_{x_0}(t)$ is absolutely continuous and hence satisfies Lusin's N -property.

Take any $x_0 \in B$, define $\Pi_{x_0} := \{(x, t, y) \in \mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R} \mid x = x_0\} \cong \mathbb{R}^2$ and $\mathcal{A}_{x_0} := \{L \cap \Pi_{x_0} \mid L \in \mathcal{A}\} \setminus \{\emptyset\}$, then $\Pi_{x_0} \supseteq \{(x_0, t, f_{x_0}(t)) \mid t \in I\} = \Gamma_{f_{x_0}}$ and $\cup \mathcal{A}_{x_0} = (\cup \mathcal{A}) \cap \Pi_{x_0} \supseteq (\cup \mathcal{A}) \cap \Gamma_{f_{x_0}} = \Gamma_{f_{x_0}}$. For any $L \cap \Pi_{x_0} \in \mathcal{A}_{x_0}$, since $\text{codim } L = 1$, $\dim \Pi_{x_0} = 2$, and $L \cap \Pi_{x_0} \neq \emptyset$, by Krull's principle ideal theorem we have that $\dim L \cap \Pi_{x_0} = 1$ or 2 . Since L and Π_{x_0} , and hence $L \cap \Pi_{x_0}$ are affine spaces, we have that $L \cap \Pi_{x_0} = \Pi_{x_0}$ or $L \cap \Pi_{x_0}$ is an affine line in Π_{x_0} . We claim that $\dim_{\mathcal{H}} \cup \mathcal{A}_{x_0} = 2$. Indeed, if $\Pi_{x_0} \in \mathcal{A}_{x_0}$ then $\cup \mathcal{A}_{x_0} = \Pi_{x_0}$ and hence $\dim_{\mathcal{H}} \cup \mathcal{A}_{x_0} = 2$, if $\Pi_{x_0} \notin \mathcal{A}_{x_0}$ then \mathcal{A}_{x_0} is a family of affine lines covers $\Gamma_{f_{x_0}}$, by Corollary 9 in [9] we have $\dim_{\mathcal{H}} \cup \mathcal{A}_{x_0} = 2$.

Define $\mathcal{A}_B := \prod_{x_0 \in B} \mathcal{A}_{x_0}$ then $\cup \mathcal{A}_B = \prod_{x_0 \in B} (\cup \mathcal{A}_{x_0}) \subseteq \cup \mathcal{A}$ and $\{\cup \mathcal{A}_{x_0}\}_{x_0 \in B}$ are vertical sections of $\cup \mathcal{A}$. Therefore by the Fubini type theorem (see e.g. [4]) we have that $\dim_{\mathcal{H}} \cup \mathcal{A}_B \geq \dim_{\mathcal{H}} B + 2 = (n-1) + 2 = n+1$. Since $\cup \mathcal{A}_B \subseteq \cup \mathcal{A} \subseteq \mathbb{R}^{n+1}$, we obtain that $\dim_{\mathcal{H}} \cup \mathcal{A} = n+1$. \blacksquare

Theorem 3.2.2. *Let M be a nonlinear twice differentiable hypersurface in \mathbb{R}^{n+1} . If \mathcal{A} is a family of hyperplanes in \mathbb{R}^{n+1} s.t. $\cup \mathcal{A} \supseteq M$, then $\dim_{\mathcal{H}} \cup \mathcal{A} = n+1$.*

Proof. Since k -th differentiability is preserved under restrictions and differentiable functions also satisfies Lusin's N -property, the same proof as in Theorem 3.2.1 yields the desired result. \blacksquare

The results above show that the union of any family of hyperplanes that covers a (sufficiently smooth) nonlinear hypersurface in \mathbb{R}^{n+1} always has full Hausdorff dimension. However if we drop the nonlinearity condition then the Hausdorff dimension of the union can be any arbitrary real number between n and $n+1$.

The corresponding constructions are based on the following theorem, which is proved by Falconer and Mattila using energy integrals.

Theorem 3.2.3. *(Theorem 3.2 in [5]): Let $X, E \subseteq \mathbb{R}^{n+1}$ be non-empty Borel sets s.t. $\forall p \in E$ $\mathcal{L}^n(X \cap L(p)) > 0$, then $\dim_{\mathcal{H}} X \cap \bigcup_{p \in E} L(p) = \dim_{\mathcal{H}} \bigcup_{p \in E} L(p) n + \min\{\dim_{\mathcal{H}} E, 1\}$.*

Moreover, if $\dim_{\mathcal{H}} E > 1$ then $\mathcal{L}^n \left(X \cap \bigcup_{p \in E} L(p) \right) > 0$.

(Here for any $q := (a, b) \in \mathbb{R}^n \times \mathbb{R}$ we denote by $L(q)$ the hyperplane $\{(x, y) \in \mathbb{R}^n \times \mathbb{R} \mid y = a^T x + b\}$)

Proposition 3.2.4. *Let M be a linear hypersurface in \mathbb{R}^{n+1} . For any $s \in [n, n+1]$, \exists family \mathcal{A} of hyperplanes in \mathbb{R}^{n+1} s.t. $\cup \mathcal{A} \supseteq M$ and $\dim_{\mathcal{H}} \cup \mathcal{A} = s$.*

Proof. Wlog we assume that M is an open subset of $L(0)$. Let C be a $s-n$ dimensional Cantor set embedded in \mathbb{R}^{n+1} , and denote $X := \mathbb{R}^{n+1}$ and $E := C \cup \{0\}$. Define $\mathcal{A} = \{L(p) \mid p \in E\}$ then $\cup \mathcal{A} \supseteq L(0) \supseteq M$. Since $X, E \subseteq \mathbb{R}^{n+1}$ are Borel sets s.t. $\forall p \in E$ $\mathcal{L}^n(X \cap L(p)) = \mathcal{L}^n(L(p)) = +\infty$, we obtain that $\dim_{\mathcal{H}} \cup \mathcal{A} = \dim_{\mathcal{H}} \bigcup_{p \in E} L(p) = n + \min\{\dim_{\mathcal{H}} E, 1\} = n + (s-n) = s$. \blacksquare

4. GENERIC C^1 VECTOR BUNDLES

4.1. Genericity of Vector Bundles. In this section we study the conditions for a C^1 vector bundle to attain expected size. In section 2 we have shown that normal bundles always have large

size while tangent bundles do not. Here, assume C^1 smoothness, we will prove that if a vector bundle of a submanifold M is in general position with the tangent bundle of M then it attains expected size.

Recall that a k_1 -subspace V_1 and a k_2 -subspace V_2 of \mathbb{R}^n is in general position iff $\dim V_1 \cap V_2 = \max\{(k_1 + k_2) - n, 0\}$. We extend this notion naturally to vector bundles, and give a definition of generic vector bundle in terms of tangency.

Definition 4.1.1. A C^1 vector bundle E defined by $\varphi : M \rightarrow \text{Gr}_k(n)$ is said to be in general position with TM at $p \in M$ iff $\dim \varphi(p) \cap T_p M = \max\{(k + d) - n, 0\}$. E is said to be generic iff $\exists p \in M$ s.t. E is in general position with TM at p .

It is clear that in definition 4.1.1 if $k \leq n - d$, then E is in general position with TM at $p \in M$ iff $\varphi(p) \cap T_p M = 0$.

Proposition 4.1.2. Let E be a generic C^1 k -vector bundle over C^1 d -submanifold M in \mathbb{R}^n and $m := \min\{k + d, n\}$, then $\mathcal{L}^m(\Delta_* E) > 0$. Moreover, if $m = n$ then $\text{int}(\Delta_* E) \neq \emptyset$.

Proof. Denote by $\varphi : M \rightarrow \text{Gr}_k(n)$ the C^1 map defines E . Wlog assume that $0 \in M$ and E is in general position with TM at 0 . We consider the following two cases.

Case 1: $k \leq n - d$. In this case $m = k + d$.

Since $\varphi(0) \cap T_0 M = 0$, there exists a $(n - d)$ -subspace V of \mathbb{R}^n s.t. $\psi(0) \subseteq V$ and V is transverse to $T_0 M$. By continuity \exists common trivializing chart U of E and TM at the vicinity of 0 , s.t. $\forall p \in U, T_p M$ is transverse to V . Denote by P_V the orthogonal projection onto V^\perp , then (U, P_V) is a chart of M , i.e. $\Omega := P_V(U)$ is open in $V^\perp \cong \mathbb{R}^d$ and $\exists C^1$ function $f : \Omega \rightarrow \mathbb{R}^{n-d}$ s.t. $U = \Gamma_f$. Let $F : \Omega \times \mathbb{R}^k \rightarrow \mathbb{R}^{2n}$ be the trivialization over U , i.e. $F(x, \xi) = ((x, f(x)), (S(x)\xi, T(x)\xi))$ where $S : \Omega \rightarrow \mathbb{R}^{k \times d}$ and $T : \Omega \rightarrow \mathbb{R}^{k \times (n-d)}$ are matrix-valued C^1 functions, then by the construction of P_V we have $S(0) = 0$ and $rkT(0) = k$. Therefore $\Delta_* F(x, \xi) = (x + S(x)\xi, f(x) + T(x)\xi)$ and

$$\text{hence } \left. \frac{\partial \Delta_* F}{\partial(x, \xi)} \right|_{(0,0)} = \begin{bmatrix} Id_d + \left(\frac{\partial S_i^j(x)}{\partial x^k} \xi^i \right) & * \\ S(x) & T(x) \end{bmatrix}_{(0,0)} = \begin{bmatrix} Id_d & * \\ 0 & T(0) \end{bmatrix} \text{ has full rank } k + d.$$

Therefore by the implicit function theorem, \exists open subset Ω_0 of $\Omega \times \mathbb{R}^k$, s.t. $\Delta_* F|_{\Omega_0}$ parametrizes a $C^1(k + d)$ -submanifold of \mathbb{R}^n and hence $\mathcal{L}^{k+d}(\Delta_* F(\Omega_0)) = \text{Vol}_{k+d}(\Delta_* F(\Omega_0)) > 0$. Since $\Delta_* E \supseteq \Delta_* F(\Omega \times \mathbb{R}^k) \supseteq \Delta_* F(\Omega_0)$, we obtain that $\mathcal{L}^{k+d}(\Delta_* E) \geq \mathcal{L}^{k+d}(\Delta_* F(\Omega_0)) > 0$. Moreover, if $k + d = m = n$ then $\Delta_* F(\Omega_0)$ is a n -submanifold, i.e. an open subset of \mathbb{R}^n , and hence $\text{int}(\Delta_* E) \supseteq \Delta_* F(\Omega_0) \neq \emptyset$.

Case 2: $k > n - d$. In this case $m = n$.

Denote $\ell := (k + d) - n$. Since $\dim \varphi(0) \cap T_0 M = \ell$, by continuity \exists common trivializing chart N of E and TM at the vicinity of 0 s.t. $\forall p \in N$ we have $\dim \varphi(p) \cap T_p M \equiv \ell$. Therefore pullback E by inclusion $N \xrightarrow{i} M$ then $E_0 := i^* E \cap TN$ is locally trivial and hence a C^1 ℓ -vector bundle over N . By Swan's theorem we have the splitting $i^* E = E_0 \oplus E_0^\perp$ where E_0^\perp is a $C^1(k - \ell)$ -vector bundle over N . Since $k - \ell = k - ((k + d) - n) = n - d$ and $E_0^\perp \cap TN = N \times \{0\}$ we have that E_0^\perp is a generic $C^1(n - d)$ -vector bundle over C^1 d -submanifold N in \mathbb{R}^n . By Case 1 we have $\text{int}(\Delta_* E_0^\perp) \neq \emptyset$. Since $E \supseteq i^* E \supseteq E_0^\perp$ we conclude that $\Delta_* E \supseteq \Delta_* E_0^\perp$ has non-empty interior. \blacksquare

Assume that the base manifold is not a point, then by Definition 4.1.1 it is clear that a C^1 line bundle is non-generic iff it is a C^1 distribution, i.e. a C^1 line subbundle of the tangent bundle. In this case we also say that the bundle is tangent to the base manifold.

Corollary 4.1.3. *Let \mathcal{L} be a C^1 line bundle over d -submanifold M of \mathbb{R}^n (where $1 \leq d \leq n-1$). If \mathcal{L} is not tangent to M then $\mathcal{L}^{d+1}(\Delta_*\mathcal{L}) > 0$. Moreover if M is a hypersurface then $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. Restatement of Proposition 4.1.2 for $k = 1$. ■

4.2. Semi-generic Line Bundles. We proceed by showing under which condition a non-generic C^1 -vector bundle can attain its expected size.

Firstly, we give an example of a degenerated case:

Let $\varphi^*\tau_k(n)$ be a C^1 vector bundle over C^1 submanifold M defined by $\varphi : M \rightarrow \text{Gr}_k(n)$, then $\varphi_1 := \varphi \circ \varphi^*\pi_1$ in the following diagram pulls back a C^1 vector bundle over C^1 submanifold $\varphi^*\tau_k(n)$.

$$\begin{array}{ccc}
 \varphi_1^*(\varphi^*\tau_k(n)) & & \\
 \downarrow \varphi_1^*\pi_1 & \searrow \tilde{\varphi}_1 & \\
 \varphi^*\tau_k(n) & \xrightarrow{\tilde{\varphi}} & \tau_k(n) \\
 \downarrow \varphi^*\pi_1 & \searrow \varphi_1 & \downarrow \pi_1 \\
 M & \xrightarrow{\varphi} & \text{Gr}_k(n)
 \end{array}$$

FIGURE 4.2.1

Then we have $\varphi_1^*(\varphi^*\tau_k(n)) = \{(p, u), (0, v) \in \mathbb{R}^{2n} \times \mathbb{R}^{2n} \mid u, v \in \varphi(p), p \in M\}$ and hence $\Delta_*\varphi_1^*(\varphi^*\tau_k(n)) = \{(p, u + v) \mid u, v \in \varphi(p), p \in M\} = \{(p, u) \mid u \in \varphi(p), p \in M\} = \varphi^*\tau_k(n)$.

More concretely, consider the line bundle \mathcal{L} on a ruled surface S in \mathbb{R}^3 generated naturally by the ruling, then we have $\Delta_*\mathcal{L} = S$.

Notice that in the example above, all points on the base manifold are degenerated in the sense that they are inflection points. We will show that this is not a coincidence.

For simplicity we restrict our consideration to line bundles. In this case we are able to introduce a notion of degeneracy in terms of foliation.

By Frobenius' theorem any C^1 line subbundle of the tangent bundle is integrable and hence defines a regular 1-foliation with C^2 leaves. Conversely, any regular 1-foliation \mathcal{F} with C^2 leaves generates C^1 line distribution $T\mathcal{F}$.

The C^2 smoothness of integral submanifolds allow us to get more information about further degeneracy.

Definition 4.2.1. A C^1 line distribution $\mathcal{D} := T\mathcal{F}$ over C^1 submanifold $M := \cup\mathcal{F}$ is said to be osculate to M at p iff $T_p^2\gamma \subseteq T_pM$ where $\gamma \in \mathcal{F}$ is the leaf contains p . \mathcal{D} is said to be osculate to M iff it is osculate to M at all $p \in M$.

Definition 4.2.2. A C^1 line distribution over C^2 submanifold M is said to be semi-generic iff it is not tangent or not osculate to M .

Remark 4.2.3. The condition $T_p^2\gamma \subseteq T_pM$ in Definition 4.2.1 is equivalent to the vanishing of the normal curvature κ_n of γ at p .

This definition of semi-genericity can also be justified by considering the following notion of deformation:

Definition 4.2.4. For any C^1 global section $\sigma : M \rightarrow \mathcal{L}$ of a C^1 line bundle \mathcal{L} over C^1 submanifold M in \mathbb{R}^n , define h_σ by the following diagram, where $M_\sigma := \Delta_*(\sigma(M))$.

$$\begin{array}{ccc}
 M & \xrightarrow{\sigma} & \mathcal{L} \\
 \downarrow h_\sigma & & \downarrow \Delta_* \\
 M_\sigma & \xrightarrow{i_{M_\sigma}} & \mathbb{R}^n
 \end{array}$$

FIGURE 4.2.2

h_σ is called a deformation of M along \mathcal{L} induced by σ . Moreover, h_σ is said to be ε -small or a ε -deformation iff $\|\Delta_*\sigma - i_{M_\sigma}\|_\infty < \varepsilon$.

For example, Id_M is the deformation induced by the zero section θ , and $\Delta_*\theta = i_M$ implies that Id_M is ε -small for all $\varepsilon > 0$.

A deformation is by definition a C^1 surjection, but in general not necessarily invertible and its image is not necessarily a submanifold.

Proposition 4.2.5. *Let \mathcal{L} be a semi-generic C^1 line bundle over C^1 submanifold M , then $\forall \varepsilon > 0 \exists \varepsilon$ -deformation h_σ along \mathcal{L} s.t. $M \cong M_\sigma$ is a diffeomorphism of C^1 submanifolds and $(h_\sigma^{-1})^* \mathcal{L}$ is generic over M_σ .*

Proof. If \mathcal{L} is not tangent to M then Id_M is a required deformation. It remains to consider the case that $\mathcal{L} := T\mathcal{F}$ is a distribution, where \mathcal{F} is a regular 1-foliation with C^2 leaves s.t. $\exists p_0 \in \gamma \in \mathcal{F}$ s.t. $T_{p_0}^2\gamma \not\subseteq T_{p_0}M$.

Wlog assume that $p_0 = 0 \in \mathbb{R}^n$. Let $U \subseteq M$ be a trivializing chart at the vicinity of 0 with chart map $\phi : U \rightarrow I^d$, and C^1 parametrization $\mathbf{f} : I^d \rightarrow \mathbb{R}^n$ s.t. $\mathbf{f}(0) = 0$ and $\mathbf{f} \circ \phi = \text{id}$. Since \mathcal{L} is trivial on U , there exists a C^1 unit vector field $X : I^d \rightarrow \mathbb{S}^{n-1}$ s.t. $X \circ \phi$ generates \mathcal{L} on U . Let $\rho : I^d \rightarrow \mathbb{R}$ be a compactly supported bump function with $\text{supp}(\rho) =: K$ s.t. $\|\rho\|_\infty = \rho(0) = 1$ and $\nabla_0\rho = 0$. For any $t \in \mathbb{R}$, extend $t(\rho X) \circ \phi : U \rightarrow \mathbb{R}^n$ by zero to a C^1 vector field v_t on M , and define $\sigma_t : M \rightarrow \mathcal{L}$ by $\sigma_t(p) = (p, v_t(p))$, then σ_t is a C^1 global section of \mathcal{L} . Denote by $h_t := h_{\sigma_t}$ the deformation induced by σ_t and $M_t := M_{\sigma_t}$, then $\forall p \in U$ we have $h_t(p) = p + t(\rho X) \circ \phi(p) = (\mathbf{f} + t(\rho X)) \circ \phi(p)$, and $\forall p \in M \setminus \mathbf{f}(K) \supseteq M \setminus U$ we have $h_t(p) = p + 0 = p$. We claim that $\exists \delta > 0$ s.t. $\forall t \in B_\delta^1$ h_t is a C^1 diffeomorphism. It suffices to prove that $\exists \delta > 0$ s.t. $\forall t \in B_\delta^1$, $h_t \circ \phi^{-1} = \mathbf{f} + t(\rho X) : U \rightarrow \mathbb{R}^n$ is a C^1 diffeomorphism onto its image.

For any $t \in \mathbb{R}$, define $\mathbf{f}_t := \mathbf{f} + t(\rho X)$. Take any $x \in I^d \setminus K$, then $\forall t \in \mathbb{R}$, $J_x \mathbf{f}_t = J_x \mathbf{f} + t J_x(\rho X) = J_x \mathbf{f} + t \cdot 0 = J_x \mathbf{f}$ has full rank. Take any $x \in K$, since $J_x \mathbf{f}$ has full rank, by continuity $\exists \delta_x > 0$ s.t. $\forall t \in B_\delta^1$, $J_x \mathbf{f}_t$ has full rank. By the compactness of K , $\exists \delta > 0$ s.t. $\forall x \in I^d, \forall t \in B_\delta^1$, $J_x \mathbf{f}_t$ has full rank. By the implicit function theorem $\forall t \in B_\delta^1$, we have that \mathbf{f}_t parametrizes C^1 submanifold $U_t := \mathbf{f}_t(I^d)$ and hence a C^1 diffeomorphism onto its image.

This proves that $\forall t \in B_\delta^1$ we have $h_t : M \rightarrow M_t = (M \setminus U) \cup U_t$ is a diffeomorphism of C^1 submanifolds.

For any $t \in B_\delta^1$, on $U_t = h_t(U)$, $(h_t^{-1})^* \mathcal{L}$ is generated by unit vector field $X \circ \phi \circ h_t^{-1}$, and we have $X \circ \phi \circ h_t^{-1}(h_t(0)) = X \circ \phi(0) = X(0)$ where $h_t(0) = \mathbf{f}_t \circ \phi(0) = \mathbf{f}_t(0)$. We claim that $\exists r \in]0, \delta[$ s.t. $\forall t \in]0, r[$, $(h_t^{-1})^* \mathcal{L}$ is in general position with M_t at $h_t(0)$, i.e. $X(0)$ is not tangent to U_t at $\mathbf{f}_t(0)$.

Parametrize γ at the vicinity of 0 as a integral curve of unit vector field $X \circ \phi$ i.e. $\gamma(s) := \mathbf{f}(\alpha(s))$ where $\alpha : I \rightarrow I^d$ is a C^1 curve s.t. $\dot{\gamma}(s) = X(\alpha(s))$. Wlog assume that $\alpha(0) = 0$ and denote $b := \dot{\alpha}(0) \in \mathbb{R}^n$, then we have $X(0) = X(\alpha(0)) = \dot{\gamma}(0) = \left. \frac{d}{ds} \right|_{s=0} \mathbf{f}(\alpha(s)) = (J_{\alpha(0)} \mathbf{f}) \dot{\alpha}(0) = (J_0 \mathbf{f}) b$ and $\ddot{\gamma}(0) = \left. \frac{d}{ds} \right|_{s=0} X(\alpha(s)) = (J_{\alpha(0)} X) \dot{\alpha}(0) = (J_0 X) b$. Since $T_p^2 \gamma \not\subseteq T_p M$, i.e. $[J_0 \mathbf{f} \mid \dot{\gamma}(0)] = [J_0 \mathbf{f} \mid (J_0 X) b]$ has full rank, by continuity $\exists \delta' \in]0, \delta[$, s.t. $\forall t \in]0, \delta'[$, $[J_0 \mathbf{f} + t J_0 X \mid (J_0 X) b]$ has full rank. Apply elementary transform we have $[J_0 \mathbf{f} + t J_0 X \mid (J_0 X) b] \sim \left[J_0 \mathbf{f} + t J_0 X \mid -\frac{1}{t} (J_0 \mathbf{f}) b \right] \sim [J_0 \mathbf{f} + t J_0 X \mid (J_0 \mathbf{f}) b] = [J_0 \mathbf{f} + t J_0 X \mid X(0)]$ has full rank. Since $T_0 U_t = \text{span} \left\{ \frac{\partial \mathbf{f}_t}{\partial x^i}(0) \right\}$ and $J_0 \mathbf{f}_t = J_0 \mathbf{f} + t J_0(\rho X) = J_0 \mathbf{f} + t \nabla \rho(0) \cdot X(0) + t \rho(0) J_0 X = J_0 \mathbf{f} + t J_0 X$ we conclude that $X(0) \notin T_0 U_t$, i.e. $X(0)$ is not tangent to U_t at $\mathbf{f}_t(0)$. This proves the claim.

Take $\lambda := \frac{1}{2} \min \{\varepsilon, \delta, \delta'\}$, then h_λ is a deformation along \mathcal{L} s.t. $M \xrightarrow{h_\lambda} M_\lambda$ is a diffeomorphism of C^1 submanifolds and $(h_\lambda^{-1})^* \mathcal{L}$ is generic over M_λ . Since $\|\Delta_* \sigma_\lambda - i_M\|_\infty = \|\mathbf{f}_t - \mathbf{f}\|_\infty = \|\lambda(\rho X)\|_\infty \leq |\lambda| \cdot 1 \leq \frac{\varepsilon}{2} < \varepsilon$, we have that h_λ is ε -small.

This concludes the proof. \blacksquare

Now we are prepared to state the main theorem. It follows straightforwardly from the following lemma which claim that deformation along a line bundle preserves codiagonal.

Lemma 4.2.6. *Let σ be a C^1 line bundle \mathcal{L} over C^1 submanifold M of \mathbb{R}^n if h_σ is a C^1 diffeomorphism then $\Delta_* (h_\sigma^{-1})^* \mathcal{L} = \Delta_* \mathcal{L}$.*

Proof. Denote by $\varphi : M \rightarrow \mathbb{P}^{n-1}$ the C^1 map defines \mathcal{L} . Since $\forall p \in M, \sigma(p) \in \varphi(p)$, we have that $\Delta_* (h_\sigma^{-1})^* \mathcal{L} = \Delta_* \{(h_\sigma(p), u) \mid u \in \varphi(p), p \in M\} = \{p + \sigma(p) + u \mid u \in \varphi(p), p \in M\} = \{p + u \mid u \in \varphi(p), p \in M\} = \Delta_* \{(p, u) \mid u \in \varphi(p), p \in M\} = \Delta_* \mathcal{L}$. \blacksquare

Theorem 4.2.7. *Let \mathcal{L} be a semi-generic C^1 line bundle over a C^1 d -submanifold M in \mathbb{R}^n (where $1 \leq d \leq n-1$) then $\mathcal{L}^{d+1}(\Delta_* \mathcal{L}) > 0$. Moreover, if M is a hypersurface then $\text{int}(\Delta_* \mathcal{L}) \neq \emptyset$.*

Proof. Since \mathcal{L} is semi-generic, by Proposition 4.2.5 \exists deformation h_σ along \mathcal{L} s.t. h_σ is a C^1 diffeomorphism and $(h_\sigma^{-1})^* \mathcal{L}$ is generic, By Corollary 4.1.3 we have $\mathcal{L}^{d+1}(\Delta_* (h_\sigma^{-1})^* \mathcal{L}) > 0$, and if $d = n-1$ then $\text{int}(\Delta_* (h_\sigma^{-1})^* \mathcal{L}) \neq \emptyset$. By Lemma 4.2.6 we have $\Delta_* \mathcal{L} = \Delta_* (h_\sigma^{-1})^* \mathcal{L}$, and the statement follows immediately. \blacksquare

We discuss an application of Theorem 4.2.7 to C^2 submanifolds. In this case the degeneracy of line bundles can be restricted by the geometry of the base manifold.

Lemma 4.2.8. *Let M be a C^2 submanifold, γ be a twice differentiable regular curve on M , and p be a point on γ . If $T_p^2\gamma \subseteq T_pM$ then p is an inflection point of M .*

Proof. Take local chart $U \subseteq M$ at the vicinity of p s.t. $U = \Gamma_f$ where up to rigid motion and homothety $f : I^d \rightarrow \mathbb{R}^{n-d}$ is a C^2 map with $(0, f(0)) = p$ and $J_0f = 0$.

Parametrize γ at the vicinity of p by $\gamma(t) := (\alpha(t), f(\alpha(t)))$ where $\alpha : I \rightarrow I^d$ and $\ddot{\alpha}(0) = u$, then $\dot{\gamma}(t) = (\dot{\alpha}(t), (J_{\alpha(t)}f)\dot{\alpha}(t))$ and $\ddot{\gamma}(0) = (\ddot{\alpha}(0), (J_{\alpha(0)}f)\ddot{\alpha}(0) + \dot{\alpha}(0)^T (\text{Hess}_{\alpha(0)}f)\dot{\alpha}(0)) = (u, (J_0f)u + v^T (\text{Hess}_0f)v)$, where Hess_0f is the Hessian tensor of f at 0.

Since $T_p^2\gamma \subseteq T_pM$, we have $\ddot{\gamma}(0) \in T_pM$. Since $(u, (J_0f)u) \in T_pM$ we have $(0, v^T (\text{Hess}_0f)v) = \ddot{\gamma}(0) - (u, (J_0f)u) \in T_pM$. Therefore we obtain that $(0, v^T (\text{Hess}_0f)v) = (0, (J_0f)0) = (0, 0)$, i.e. $v^T (\text{Hess}_0f)v = 0$. Since γ is regular, we have $(\dot{\alpha}(0), 0) = (\dot{\alpha}(0), (J_0f)\dot{\alpha}(0)) = \dot{\gamma}(0) \neq 0$, i.e. $v = \dot{\alpha}(0) \neq 0$. Therefore Hess_0f is degenerated and f is not a Morse function at 0, i.e. $p = (0, f(0))$ is an inflection point of M . \blacksquare

Theorem 4.2.9. *Let M be a C^2 d -submanifold of \mathbb{R}^n (where $1 \leq d \leq n-1$). If not all points of M are inflection points, then $\forall C^1$ line bundle \mathcal{L} over M we have $\mathcal{L}^{d+1}(\Delta_*\mathcal{L}) > 0$, and moreover if M is a hypersurface then $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. Since $\exists p \in M$ s.t. p is not an inflection point, by Lemma 4.2.8 \forall regular 1-foliation \mathcal{F} of M with C^2 leaves, we have $T_p^2\gamma \not\subseteq T_pM$ where γ is the leaf contains p . Therefore $\forall C^1$ line bundle \mathcal{L} on M , \mathcal{L} is semi-generic. The statement then follows immediately from Theorem 4.2.7. \blacksquare

5. LINE BUNDLES OVER HYPERPLANES AND ELLIPSOIDS

In this section we focus on (continuous) line bundles over classical geometric objects such as hyperplanes, convex curves and ellipsoids.

5.1. Algebraic Topological Lemmas. Before we discuss the size of line bundles, we shall introduce several useful lemmas.

Recall that for any $u, v \in \mathbb{S}^n \subseteq \mathbb{R}^{n+1}$ define $\angle(u, v) := \arccos(u^T v)$ then \angle coincides with the geodesic distance on \mathbb{S}^n w.r.t. the induced Riemannian metric from \mathbb{R}^{n+1} .

Definition 5.1.1. For any $a \in \mathbb{S}^n$ and $\theta > 0$, define $V_\theta(a) := \{u \in \mathbb{S}^n \mid \angle(u, a) \leq \theta\}$ the geodesic disk at a with radius θ , and $W_\theta(a) := \{u \in \mathbb{S}^n \mid \angle(u, a) = \theta\}$ its boundary.

We have the following analog of Borsuk's non-retraction theorem. The proof is adapted from Lemma 2.5 in [3] and the condition is modified and slightly weakened for our purpose.

Lemma 5.1.2. *Let $a \in \mathbb{S}^n$ and $0 < \varepsilon < \theta < \frac{\pi}{2}$. If $f : V_\theta(a) \rightarrow \mathbb{S}^n$ is a continuous map s.t. $\exists b \in V_{\pi-\theta-2\varepsilon}(-a)$ s.t. $b \notin f(V_\theta(a))$, and $\forall u \in W_\theta(a) \angle(u, f(u)) < \varepsilon$, then $f(V_\theta(a)) \supseteq V_{\theta-\varepsilon}(a)$.*

Proof. Provided that $\exists c \in V_{\theta-\varepsilon}(a)$ s.t. $c \notin f(V_\theta(a))$. Denote $X := \mathbb{S}^{n-1} \setminus \{b, c\}$ and $A := V_{\theta+\varepsilon}(a) \setminus V_{\theta-\varepsilon}(a)$, i.e. the ε -neighborhood of $W_\theta(a)$. Since $\forall u \in A$ clearly $\exists!$ distance-minimizing geodesic connects u and $W_\theta(a)$, we conclude that the metric projection $P := P_{W_\theta(a)} : A \rightarrow W_\theta(a)$ is a well-defined (single valued) map. Since by assumption $f(W_\theta(a)) \subseteq A$, we have that $P \circ f|_{W_\theta(a)}$ is a well-defined continuous map.

Take any $u \in W_\theta(a)$, since $f(u) \in A$ the ε -neighborhood of $W_\theta(a)$, we have $\angle(f(u), P(f(u))) \leq \varepsilon$. Therefore $\angle(u, P(f(u))) \leq \angle(u, f(u)) + \angle(f(u), P(f(u))) < \varepsilon + \varepsilon < 2\theta$. Denote by u' the antipodal

point of u in $W_\theta(a) \equiv \mathbb{S}^{n-1}$, then $\angle(u, u') = 2\theta$. Therefore $\forall u \in W_\theta(a)$ we have $P(f(u)) \neq u'$. Therefore $P \circ f|_{W_\theta(a)}$ is homotopic to identity. By Brouwer's theorem $P \circ f|_{W_\theta(a)} \simeq id_{\mathbb{S}^{n-1}}$ is not null-homotopic, this gives an obstruction for extending $P \circ f|_{W_\theta(a)}$ to $V_\theta(a)$.

Since $X \simeq W_\theta(a)$, it is easy to check that P extends continuously to a deformation retraction $\tilde{P} : X \rightarrow W_\theta(a)$. Since by assumption $b, c \notin f(V_\theta(a))$, i.e. $f(V_\theta(a)) \supseteq X$, we obtain that $\tilde{P} \circ f$ is a well-defined continuous map extends $P \circ f|_{W_\theta(a)}$, contradiction.

This proves that $f(V_\theta(a)) \supseteq V_{\theta-\varepsilon}(a)$. \blacksquare

The next lemma describes the size of a special continuous family of half-lines parametrized by a disk.

Proposition 5.1.3. *Take continuous maps $\alpha, \beta : \mathbb{D}^n \rightarrow \mathbb{R}^n$ s.t. $\alpha|_{\partial\mathbb{D}^n} = Id$, and for any $x \in \mathbb{D}^n$, $\gamma_x(t) := (t, t\alpha(x) + \beta(x))$, $t \in \mathbb{R}_+$, then $\bigcup_{x \in \mathbb{D}^n} \gamma_x$ contains an unbounded open subset of \mathbb{R}^{n+1} .*

Proof. Denote $\mathbb{S}_+^n := \{(h, x) \in \mathbb{R} \times \mathbb{R}^n \mid \|(h, x)\| = 1, h > 0\}$, $\Pi := \{(h, x) \in \mathbb{R} \times \mathbb{R}^n \mid h = 1\}$, $D := \{(1, x) \mid \|x\| \leq 1\}$ and $a := (1, 0) \in D \subseteq \Pi$. Define $\alpha_1 : D \rightarrow \Pi$ by $\alpha_1(1, x) := (1, \alpha(x))$, $\beta_0 : D \rightarrow \mathbb{R}^{n+1}$ by $\beta_0(1, x) = (0, \beta(x))$, and $\pi : \Pi \rightarrow \mathbb{S}_+^n$ by $\pi(p) := \frac{p}{\|p\|}$, then π is a homeomorphism s.t. $\pi(D) = V_{\frac{\pi}{4}}(a) \subseteq \mathbb{S}_+^n$ and induces $\alpha_1^* := \pi \circ \alpha_1 \circ \pi^{-1} : V_{\frac{\pi}{4}}(a) \rightarrow \mathbb{S}_+^n$. Apply the definitions above we rewrite $\gamma_x(t) = t\alpha_1(1, x) + \beta_0(1, x) = t\pi \circ \alpha_1(1, x) + \beta_0(1, x) = t\alpha_1^*(\pi(1, x)) + \beta_0\pi^{-1}(\pi(1, x))$. For any $u \in V_{\frac{\pi}{4}}(a)$ denote $\gamma_u(t) := t\alpha_1^*(u) + \beta_0\pi^{-1}(u)$, $t \in \mathbb{R}_+$, then $\{\gamma_x\}_{x \in \mathbb{D}^n}$ is in 1-1 correspondence with $\{\gamma_u\}_{u \in V_{\frac{\pi}{4}}(a)}$, and hence $\bigcup_{x \in \mathbb{D}^n} \gamma_x = \bigcup_{u \in V_{\frac{\pi}{4}}(a)} \gamma_u$.

Since $\beta_0\pi^{-1}(V_{\frac{\pi}{4}}(a)) = \beta_0(D) = \beta(\mathbb{D}^n) \times \{0\}$ is compact, there exists $r > 0$ s.t. $B_r^{n+1} \supseteq \beta_0\pi^{-1}(V_{\frac{\pi}{4}}(a))$. Take $\rho \geq r$ then by Jordan's curve theorem $\forall u \in V_{\frac{\pi}{4}}(a)$, $\gamma_u \cap \partial B_\rho^{n+1}$ at an unique point $p_{u, \rho}$. Define $\psi_\rho : V_{\frac{\pi}{4}}(a) \rightarrow \mathbb{S}^n$ by $\psi_\rho(u) := \frac{p_{u, \rho}}{\|p_{u, \rho}\|} = \frac{1}{\rho} p_{u, \rho}$ then it is easy to check that ψ_ρ is continuous.

By the construction of ψ_ρ , $\forall \varepsilon > 0, \exists R \geq r$ s.t. $\forall \rho > R$ for any $u \in V_{\frac{\pi}{4}}(a)$ we have $\angle(\alpha_1^*(u), \psi_\rho(u)) < \varepsilon$. Take $\varepsilon = \frac{\pi}{12}$, then for any $\rho > R$ we have $\psi_\rho(V_{\frac{\pi}{4}}(a)) \subseteq \bigcup_{u \in \mathbb{S}_+^n} V_{\frac{\pi}{12}}(u) = V_{\frac{7\pi}{12}}(a)$, in particular we have $-a \notin \psi_\rho(V_{\frac{\pi}{4}}(a))$. Since $\forall x \in \partial\mathbb{D}^n$, $\alpha_1(1, x) = (1, \alpha(x)) = (1, x)$ i.e. $(1, x)$ is a fixed point of α_1 , and α_1^* is topological conjugate with α_1 , we conclude that $\forall u \in W_{\frac{\pi}{4}}(a)$, $\alpha_1^*(u) = u$. Therefore for any $\rho > R$, $\forall u \in W_{\frac{\pi}{4}}(a)$ we have $\angle(u, \psi_\rho(u)) = \angle(\alpha_1^*(u), \psi_\rho(u)) < \frac{\pi}{12}$. By Lemma 5.1.2 we have that $\psi_\rho(V_{\frac{\pi}{4}}(a)) \supseteq V_{\frac{\pi}{6}}(a)$. Therefore $\bigcup_{x \in \mathbb{D}^n} \gamma_x = \bigcup_{u \in V_{\frac{\pi}{4}}(a)} \gamma_u \supseteq \bigcup_{\rho > R} \psi_\rho(V_{\frac{\pi}{4}}(a)) \supseteq \bigcup_{\rho > R} \rho V_{\frac{\pi}{6}}(a) \supseteq \{tu \mid \angle(u, a) < \frac{\pi}{6}, t > 0\} \setminus \bar{B}_R$, where $\{tu \mid \angle(u, a) < \frac{\pi}{6}, t > 0\} \setminus \bar{B}_R$ is clearly an unbounded open subset of \mathbb{R}^{n+1} . \blacksquare

By considering the family of lines in projective spaces and passing to an another affine chart, we obtain the following dual proposition.

Proposition 5.1.4. *Take continuous map $\beta : \mathbb{D}^n \rightarrow \mathbb{R}^n$, $f \in C(\mathbb{D}^n)$ s.t. $f|_{\partial\mathbb{D}^n} \equiv \text{constant}$, and for any $x \in \mathbb{D}^n$, $\ell_x(t) := (t + f(x), t\beta(x) + x)$, $t \in \mathbb{R}_+$, then $\text{int}\left(\bigcup_{x \in \mathbb{D}^n} \ell_x\right) \neq \emptyset$.*

Proof. Wlog we assume that $f|_{\partial\mathbb{D}^n} \equiv 0$.

Identify $\mathbb{R}^{n+1} = \{(a^1, \dots, a^{n+1}) \mid a^i \in \mathbb{R}\} \equiv \{[1 : a^1 : \dots : a^{n+1}] \mid a^i \in \mathbb{R}\} = U_0 \hookrightarrow \mathbb{P}^{n+1}$ with the standard affine chart and denote $U_1 := \{[a^0 : 1 : a^2 : \dots : a^{n+1}] \mid a^i \in \mathbb{R}\}$.

Denote $\Pi_0 := \mathbb{P}^{n+1} \setminus U_1 = \{[1 : 0 : a^2 : \dots : a^{n+1}] \mid a^i \in \mathbb{R}\} \subseteq U_0$ and $\Pi_1 := \mathbb{P}^{n+1} \setminus U_0 = \{[0 : 1 : a^2 : \dots : a^{n+1}] \mid a^i \in \mathbb{R}\} \subseteq U_1$. In homogeneous coordinates we have $\beta([1 : 0 : x^1 : \dots : x^n]) = [0 : 1 : \beta^1(x) : \dots : \beta^n(x)]$ and $\Gamma_f = \{[1 : f(x) : x^1 : \dots : x^n] \mid x \in \mathbb{D}^n\}$. For any $x \in \mathbb{D}^n$, define $\bar{\ell}_x : \mathbb{P}^1 \rightarrow \mathbb{P}^{n+1}$ by $\bar{\ell}_x([\lambda : \mu]) := [\lambda : \lambda f(x) + \mu : \lambda x^1 + \mu \beta^1(x) : \dots : \lambda x^n + \mu \beta^n(x)]$, then $\bar{\ell}_x \cong \mathbb{P}^1$ is a projective line in \mathbb{P}^{n+1} .

Solve $\lambda f(x) + \mu = 1$ we obtain $\mu = 1 - \lambda f(x)$. Therefore $\bar{\ell}_x \cap U_1 = \{[\lambda : 1 : \lambda x^1 + (1 - \lambda f(x))\beta^1(x) : \dots : \lambda x^n + (1 - \lambda f(x))\beta^n(x)] \mid \lambda \in \mathbb{R}\} = \{[\lambda : 1 : \lambda(x^1 - f(x)\beta^1(x)) + \beta^1(x) : \dots : \lambda(x^n - f(x)\beta^n(x)) + \beta^n(x)] \mid \lambda \in \mathbb{R}\} \equiv \{(\lambda, \lambda(x - f(x)\beta(x)) + \beta(x)) \mid \lambda \in \mathbb{R}\}$. Denote $\alpha(x) := x - f(x)\beta(x)$ then $\alpha : \mathbb{D}^n \rightarrow \mathbb{R}^n$ is a continuous map s.t. $\forall x \in \partial\mathbb{D}^n, \alpha(x) = x - 0 \cdot \beta(x) = x$. Therefore by

Proposition 5.1.3 we have $\left(\bigcup_{x \in \mathbb{D}^n} \bar{\ell}_x\right) \cap U_1$ has non empty interior in $\mathbb{R}^{n+1} \equiv U_1$ and hence has non empty interior in \mathbb{P}^{n+1} . In particular $\bigcup_{x \in \mathbb{D}^n} \bar{\ell}_x$ has non empty interior in \mathbb{P}^{n+1} .

Since U_0 is a dense open subset of \mathbb{P}^{n+1} , we have that $\left(\bigcup_{x \in \mathbb{D}^n} \bar{\ell}_x\right) \cap U_0$ has non empty interior in $U_0 \equiv \mathbb{R}^{n+1}$. Since $\bar{\ell}_x \cap U_0 = \{[1 : f(x) + \mu : x^1 + \mu \beta^1(x) : \dots : x^n + \mu \beta^n(x)] \mid \mu \in \mathbb{R}\} \equiv \{(\mu + f(x), \mu \beta(x) + x) \mid \mu \in \mathbb{R}\} = \ell_x$. We conclude that $\bigcup_{x \in \mathbb{D}^n} \ell_x = \bigcup_{x \in \mathbb{D}^n} (\bar{\ell}_x \cap U_0) = \left(\bigcup_{x \in \mathbb{D}^n} \bar{\ell}_x\right) \cap U_0$ has non empty interior in \mathbb{R}^{n+1} . \blacksquare

In order to reformulate the propositions above using the language of fiber bundles, we introduce the following notion of transversality.

Definition 5.1.5. Let E be a k -vector bundle over a subset X of \mathbb{R}^n defined by $\varphi : X \rightarrow \text{Gr}_k(n)$, and V be a $(n - k)$ -subspace of \mathbb{R}^n , then E is said to be transverse to V (denote by $E \pitchfork V$) iff $\forall x \in X \varphi(x) \pitchfork V$.

Theorem 5.1.6. Let \mathcal{L} be a line bundle over Γ_f where $f \in C(\mathbb{D}^n)$ with $f|_{\partial\mathbb{D}^n} \equiv \text{constant}$, if $\mathcal{L} \pitchfork \mathbb{R}^n \times \{0\}$, then $\text{int}(\Delta_* \mathcal{L}) \neq \emptyset$.

Proof. Coordinate-free restatement of Proposition 5.1.4 using Definition 5.1.5. \blacksquare

For simplicity, for any subset X of \mathbb{R}^n and $f \in C(X)$ we introduce notation $P_f := \text{id}_X \times 0 : \Gamma_f \rightarrow X \times \{0\}$ for the projection $(x, f(x)) \mapsto (x, 0)$. Since it is clear that P_f is a homeomorphism, pullback by P_f^* is a 1 - 1 correspondence, i.e. all line bundles over Γ_f have the form $P_f^* \mathcal{L}$ where \mathcal{L} is a line bundle over $X \times \{0\}$, and vice versa.

Therefore the following reformulation is also useful:

Corollary 5.1.7. Let \mathcal{E} be a line bundle over $\mathbb{D}^n \times \{0\} \subseteq \mathbb{R}^n \times \mathbb{R}$ s.t. $\mathcal{E} \pitchfork \mathbb{R}^n \times \{0\}$ then $\forall f \in C(\mathbb{D}^n)$ with $f|_{\partial\mathbb{D}^n} \equiv \text{constant}$, we have $\text{int}(\Delta_* P_f^* \mathcal{E}) \neq \emptyset$.

5.2. Line Bundle over Hyperplanes, Convex Curves, and Spheres. Now we shall discuss the application of the theorems above.

We start with the line bundles over linear hypersurfaces and, in particular, hyperplanes.

Theorem 5.2.1. Let M be a linear hypersurface and \mathcal{L} be a line bundle over M , then $\text{int}(\Delta_* \mathcal{L}) \neq \emptyset$ iff \mathcal{L} is not tangent to M .

Proof. Wlog assume that $M := \Omega \times \{0\} \subseteq \mathbb{R}^n \times \mathbb{R}$ where Ω is an open subset of \mathbb{R}^n .

\implies : Provided that \mathcal{L} is tangent to M , then $\Delta_*\mathcal{L} \subseteq \Delta_*TM = \mathbb{R}^n \times \{0\}$ and hence $\dim_{\mathcal{H}} \Delta_*\mathcal{L} \leq \dim \mathbb{R}^n = n$, in particular $\text{int}(\Delta_*\mathcal{L}) = \emptyset$.

\impliedby : Denote by $\varphi : M \rightarrow \mathbb{P}^n$ the continuous map defines \mathcal{L} , then by assumption $\exists x_0 \in \Omega$, s.t. $\varphi(x_0, 0) \pitchfork \mathbb{R}^n \times \{0\}$. By continuity, up to rigid motion and homothety we assume $\mathbb{D}^n \subseteq \Omega$ and $\forall x \in \mathbb{D}^n, \varphi(x, 0) \pitchfork \mathbb{R}^n \times \{0\}$. Take $f \equiv 0$ then $P_f = Id_{\mathbb{D}^n \times \{0\}}$ and hence $P_f^*\mathcal{L} = \mathcal{L}$. By Corollary 5.1.7 we have $\text{int}(\Delta_*\mathcal{L}) = \text{int}(\Delta_*P_f^*\mathcal{L}) \neq \emptyset$. \blacksquare

We also have the following application to convex functions and convex curves.

Theorem 5.2.2. *Let $f : I \rightarrow \mathbb{R}$ be a strictly convex function then \forall line bundle \mathcal{L} over Γ_f we have $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. Let \mathcal{E} be the line bundle over I s.t. $P_f^*\mathcal{E} = \mathcal{L}$ and denote by $\varphi : I \rightarrow \mathbb{P}^1$ the continuous map defines \mathcal{E} .

We consider the following two cases:

Case 1: $\forall x \in I, \varphi(x)$ is a supporting hyperplane of the epigraph of f at $(x, f(x))$. For any $a \in I$, since $\Gamma_f \cap \{(x, y) \in \mathbb{R}^2 \mid x > a\} \neq \emptyset$ and $\Gamma_f \cap \{(x, y) \in \mathbb{R}^2 \mid x < a\} \neq \emptyset$, we have $\varphi(a)$ is not the vertical line. Denote by $U_0 := \{[x : y] \mid x \neq 0\} \subseteq \mathbb{P}^1$ the standard affine chart and $\pi_0 := [x : y] \mapsto \frac{y}{x}$ the chart map, then $\varphi(I) \subseteq U_0$. Define $g : I \rightarrow \mathbb{R}$ by $g := \pi_0 \circ \varphi$, and denote by C the set of non-differentiable points of f . Since f is convex, we have that C is countable and $I \setminus C$ is dense in I . By the continuity of $g, g(I \setminus C)$ is dense in $g(I)$ and $g(I)$ is a connected subset of \mathbb{R} , i.e. an (finite or infinite) interval.

Denote by f'_L the left derivative of f , then C is the set of discontinuity of f'_L and $\forall x \in I \setminus C$ we have $f'_L(x) = f'(x)$. Recall that for any $x \in I \setminus C$ the supporting hyperplane of the epigraph of f at $(x, f(x))$ is unique and coincides with the tangent space of Γ_f at $(x, f(x))$, we obtain that $f'_L|_{I \setminus C} \equiv g|_{I \setminus C}$. Therefore $f'_L(I \setminus C)$ is dense in interval $g(I)$, and hence f'_L has no jump discontinuity. Since the one-sided derivative of a convex function is monotonous and hence admits only jump discontinuity, we conclude that f'_L is continuous. Therefore $C = \emptyset, f'_L \equiv f'$, and f is C^1 . Moreover, since f is strictly convex, we have that f is nonlinear. By Proposition 3.1.3 we have $\text{int}(\Delta_*T\Gamma_f) \neq \emptyset$.

By the differentiability of $f, \forall x \in I$ we have $\varphi(x) = T_{(x, f(x))}\Gamma_f$. Therefore $\mathcal{L} = T\Gamma_f$, and hence $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.

Case 2: $\exists x_0 \in I$ s.t. $\varphi(x_0)$ is not a supporting hyperplane of the epigraph of f at $(x_0, f(x_0))$.

Up to rigid motion and homothety of $\mathbb{R}^2 \supseteq \Gamma_f$ wlog we assume that $f(x_0) = 0$ is the global minima of f . Since the horizontal line $\mathbb{R} \times \{0\}$ is a supporting hyperplane of the epigraph of f at $(x_0, 0)$, we have that $\varphi(0) \neq [1 : 0]$. By the continuity of φ wlog we assume that $\forall x \in I, \varphi(x) \neq [1 : 0]$, i.e. $\mathcal{E} \pitchfork \mathbb{R} \times \{0\}$.

Since f is strictly convex and attains global minima at $x_0 \in I$, there exists $\varepsilon > 0$, s.t. $\#f^{-1}(\{\varepsilon\}) = 2$. Wlog assume that $f^{-1}(\{\varepsilon\}) = \{\pm 1\} = \partial\mathbb{D}$ where $\mathbb{D} = [-1, 1] \stackrel{j}{\subseteq} I$, then $j^*\mathcal{E}$ is a line bundle over \mathbb{D} with $f|_{\partial\mathbb{D}} \equiv \varepsilon$ and $j^*\mathcal{E} \pitchfork \mathbb{R} \times \{0\}$. Therefore by Corollary 5.1.7 $\text{int}(\Delta_*P_{f|_{\mathbb{D}}}^*j^*\mathcal{E}) \neq \emptyset$.

Since $\mathbb{D} \stackrel{j}{\subseteq} I$ induces the inclusion $\Gamma_{f|_{\mathbb{D}}} \stackrel{i}{\subseteq} \Gamma_f$ where $i = P_f^{-1} \circ j \circ P_{f|_{\mathbb{D}}}$, we conclude that $\mathcal{L} = P_f^*\mathcal{E} \supseteq i^*P_f^*\mathcal{E} = P_{f|_{\mathbb{D}}}^*j^*\mathcal{E}$. Therefore $\Delta_*\mathcal{L} \supseteq \Delta_*P_{f|_{\mathbb{D}}}^*j^*\mathcal{E}$ has non-empty interior. \blacksquare

Theorem 5.2.3. *Let γ be a strictly convex curve then \forall line bundle \mathcal{L} over γ we have $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. Decompose γ into upper and lower hulls then up to rigid motion and homothety \exists strictly convex function $f : I \rightarrow \mathbb{R}$ s.t. the lower hull contains $\Gamma_f \stackrel{i}{\subseteq} \gamma$. By Theorem 5.2.2 $\text{int}(\Delta_*i^*\mathcal{L}) \neq \emptyset$. Since $\mathcal{L} \supseteq i^*\mathcal{L}$ we have $\text{int}(\Delta_*\mathcal{L}) \subseteq \text{int}(\Delta_*i^*\mathcal{L}) \neq \emptyset$. \blacksquare

Notice that the strictly convexity condition in the two theorems above cannot be weakened, since piecewise-linear curves clearly do not enjoy the desired property.

The following corollaries show that in the two theorems above if instead of a full line bundle we take any arbitrary 1 Hausdorff dimensional subset of each fiber then the image under the codiagonal morphism still attains full Hausdorff dimension.

Corollary 5.2.4. *Let $f : I \rightarrow \mathbb{R}$ be a strictly convex function, $\pi : \mathcal{L} \rightarrow \Gamma_f$ be a line bundle and $\mathcal{L}_0 \stackrel{i}{\subseteq} \mathcal{L}$ be any subset. If $\forall p \in \Gamma_f$ we have $\dim_{\mathcal{H}}(\pi \circ i)^{-1}(\{p\}) = 1$, then $\dim_{\mathcal{H}} \Delta_*\mathcal{L}_0 = 2$.*

Proof. By Theorem 5.2.3 in particular we have $\dim_{\mathcal{H}} \Delta_*\mathcal{L} = 2$.

Take any $q \in \Delta_*\mathcal{L}$ then clearly $\exists p \in \Gamma_f$ s.t. $q \in \ell := p + \pi^{-1}(\{p\})$. Since $\ell \cap \Delta_*\mathcal{L}_0 \supseteq (p + \pi^{-1}(\{p\})) \cap (p + (\pi \circ i)^{-1}(\{p\})) = p + (\pi \circ i)^{-1}(\{p\})$, we obtain that $\dim_{\mathcal{H}}(\ell \cap \Delta_*\mathcal{L}_0) \geq \dim_{\mathcal{H}}(p + (\pi \circ i)^{-1}(\{p\})) = \dim_{\mathcal{H}}(\pi \circ i)^{-1}(\{p\}) = 1$. Therefore by Corollary 2.5 in [6] we have $\dim_{\mathcal{H}} \Delta_*\mathcal{L}_0 \geq 2 \cdot 1 - 1 + \min\{1, \dim_{\mathcal{H}} \Delta_*\mathcal{L} - 1\} = 1 + \min\{1, 1\} = 2$. Since $2 \leq \dim_{\mathcal{H}} \Delta_*\mathcal{L}_0 \leq \dim_{\mathcal{H}} \mathbb{R}^2 = 2$, we conclude that $\dim_{\mathcal{H}} \Delta_*\mathcal{L}_0 = 2$. \blacksquare

Corollary 5.2.5. *Let $\pi : \mathcal{L} \rightarrow \gamma$ be a line bundle over a strictly convex curve, and $\mathcal{L}_0 \stackrel{i}{\subseteq} \mathcal{L}$ be any subset. If $\forall p \in \gamma$ we have $\dim_{\mathcal{H}}(\pi \circ i)^{-1}(\{p\}) = 1$, then $\dim_{\mathcal{H}} \Delta_*\mathcal{L}_0 = 2$.*

Proof. The same as Corollary 5.2.4. \blacksquare

Finally we discuss the application to spheres and ellipsoids.

We shall first show that similar to the hyperplane case, any non tangent line bundle attains its expected size.

Proposition 5.2.6. *Let \mathcal{L} be a line bundle over an open subset U of a n -sphere in \mathbb{R}^{n+1} , if \mathcal{L} is not tangent to U then $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. Denote by $S \subseteq \mathbb{R}^{n+1}$ the n -sphere, wlog we assume that S is centred at 0 with radius $R > 1$, then at the vicinity of the north pole $p := (0, R)$, S is the graph of $f(x) = \sqrt{R^2 - \|x\|^2}$, $\|x\| < R$. Wlog assume that U is an open neighborhood of p and \mathcal{L} is not tangent to U at p .

Denote by $\varphi : U \rightarrow \mathbb{P}^n$ the continuous map defines \mathcal{L} . Since $T_p S = \mathbb{R}^n \times \{0\}$ we have $\varphi(0, R) \cap \mathbb{R}^n \times \{0\}$. By continuity, up to a homothety $\forall x \in \mathbb{D}^n$ we have $(x, f(x)) \in U$ and $\varphi(x, f(x)) \cap \mathbb{R}^n \times \{0\}$. It is clear that $f|_{\mathbb{D}^n} \in C(\mathbb{D}^n)$ and $f|_{\partial\mathbb{D}^n} \equiv \text{Constant}$. Since $\mathcal{L} \subseteq i^*\mathcal{L}$ we conclude that $\text{int}(\Delta_*\mathcal{L}) \supseteq \text{int}(\Delta_*i^*\mathcal{L}) \neq \emptyset$. \blacksquare

As an application of Poincaré-Hopf index formula, we know that there exists no continuous nonsingular tangent vector field over even dimensional spheres. Taking this into account, from Proposition 5.2.6 one deduces that any line bundle over an even dimensional sphere generated by a continuous unit vector field attains its expected size.

Actually more is true, as we have the following proposition:

Proposition 5.2.7. *Let $n \geq 1$ and \mathcal{D} be a continuous line distribution over a n -sphere S in \mathbb{R}^{n+1} , then $\Delta_*\mathcal{D} = \mathbb{R}^{n+1} \setminus B$ where B is the open ball bounded by S .*

Proof. If $n = 1$ then S is a circle in \mathbb{R}^2 and $\mathcal{D} = TS$, by observation the statement clearly holds. It remains to proof the statement for $n \geq 2$.

Wlog assume that $S := \mathbb{S}^n = \{x \in \mathbb{R}^n \mid \|x\| = 1\} \subseteq \mathbb{R}^n$, then $B = \{\|x\| < 1\}$.

Since for any $k \geq 2$, $H^1(\mathbb{S}^k, \mathbb{Z}/2\mathbb{Z}) = H^1(\mathbb{S}^k, \mathbb{Z}) \otimes \mathbb{Z}/2\mathbb{Z} = 0 \otimes \mathbb{Z}/2\mathbb{Z} = 0$, we have that the Stiefel-Whitney class $w_1(\mathcal{D}) = 0$, and hence \mathcal{D} is generated by its non-singular section, i.e. a continuous unit vector field $X : \mathbb{S}^n \rightarrow \mathbb{S}^n$.

For any $u \in \mathbb{S}^n$ define $\ell_u(t) := u + tX(u), t \in \mathbb{R}$, and $\gamma_u(t) := u + tX(u), t \in \mathbb{R}_+$, then $\Delta_*\mathcal{L} = \bigcup_{u \in \mathbb{S}^n} \ell_u \supseteq \bigcup_{u \in \mathbb{S}^n} \gamma_u$.

Take any $\rho > 1$, then by Jordan's curve theorem $\forall u \in \mathbb{S}^n$, $\gamma_u \cap \partial B_\rho^{n+1}$ at an unique point $p_{u,\rho}$. Define $\psi_\rho : \mathbb{S}^n \rightarrow \mathbb{S}^n$ by $\psi_\rho(u) := \frac{p_{u,\rho}}{\|p_{u,\rho}\|} = \frac{1}{\rho} p_{u,\rho}$, then it is easy to check that ψ_ρ is continuous.

Take any $u \in \mathbb{S}^n$. Since $X(u) \in T_u\mathbb{S}^n$ we have that $X(u) \perp u$. Therefore for any $t \in \mathbb{R}_+$ we have $\langle u + tX(u), -u \rangle = -\langle u, u \rangle - t\langle X(u), u \rangle = -1 - t \cdot 0 = -1$ and hence $\left\langle \frac{u + tX(u)}{\|u + tX(u)\|}, -u \right\rangle = -\frac{1}{\|u + tX(u)\|} < 0$, in particular $\frac{u + tX(u)}{\|u + tX(u)\|} \neq -u$. Therefore $\forall u \in \mathbb{S}^n, \forall \rho > 1$, we have $\psi_\rho(u) \neq -u$.

Take any $\rho > 1$. Since $\forall u \in \mathbb{S}^n$, $\psi_\rho(u) \neq -u$ we have that $\psi_\rho \simeq Id_{\mathbb{S}^n}$. Since by Brouwer's theorem $Id_{\mathbb{S}^n}$ is not null-homotopic and recall that any non surjective continuous map to a sphere is null-homotopic, we conclude that ψ_ρ is surjective. Therefore $\Delta_*\mathcal{L} \supseteq \bigcup_{u \in \mathbb{S}^n} \gamma_u \supseteq \{p_{u,\rho}\}_{u \in \mathbb{S}^n} = \partial B_\rho^n$.

Therefore $\Delta_*\mathcal{L} \supseteq \bigcup_{\rho > 1} \partial B_\rho^n = \{\|x\| > 1\}$.

Since clearly $\mathbb{S}^n \subseteq \Delta_*\mathcal{L}$, we have that $\Delta_*\mathcal{L} \supseteq \{\|x\| \geq 1\}$. Since $\forall u \in \mathbb{S}^n, \ell_u$ is tangent to \mathbb{S}^n and hence $\inf_{p \in \ell_u} \|p\| = 1$, we have that $\forall x \in \{\|x\| < 1\} x \notin \ell_u$. Therefore $\forall x \in \{\|x\| < 1\}$, we have $x \notin \bigcup_{u \in \mathbb{S}^n} \ell_u = \Delta_*\mathcal{L}$.

This proves that $\Delta_*\mathcal{L} = \{\|x\| \geq 1\} = \mathbb{R}^n \setminus \{\|x\| < 1\}$. ■

Now we state our conclusive result for spheres.

Theorem 5.2.8. *Let \mathcal{L} be a line bundle over a n -sphere S in \mathbb{R}^{n+1} then $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.*

Proof. If $n = 0$ then the ambient space is \mathbb{R}^1 and clearly $\Delta_*\mathcal{L} = \mathbb{R}^1$. In particular we have that $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.

If $n \geq 1$ and \mathcal{L} is not tangent to S then by Proposition 5.2.6 $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$.

If $n \geq 1$ and \mathcal{L} is tangent to S then by Proposition 5.2.7 $\text{int}(\Delta_*\mathcal{L}) \neq \emptyset$. ■

Remark 5.2.9. By definition, ellipsoids are regular level sets of positive determined quadratic forms. Since by an affine change of coordinates one can reduce a quadratic form to its canonical form, equivalently we have that ellipsoids are images of the unit sphere under non-degenerated affine transforms. Therefore the statements in Proposition 5.2.6, 5.2.7 and Theorem 5.2.8 hold also for ellipsoids. In particular, any line bundle over an ellipsoid attains its expected size.

Remark 5.2.10. If the family of lines is not parameterized continuously, then the assertions in this section do not hold in general. For example, see [1] for detailed construction of counter examples for convex curves and high dimensional generalizations.

6. ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to Professor Keleti who taught me geometric measure theory. I would like to express my special thanks to Professor Keleti and Professor Csíkós for very useful comments and suggestions.
