

**A SHORT NONCOMPLEX PROOF FOR THE SOLUTION SET OF
HOMOGENEOUS SECOND ORDER LINEAR DIFFERENTIAL EQUATIONS
WITH CONSTANT COEFFICIENTS**

PATRIK LUNDSTRÖM

ABSTRACT. We provide a short proof, not utilizing complex numbers, for the solution set of homogeneous second order linear differential equations with constant coefficients.

Several papers (see e.g. [1, 2, 3, 4, 5]) discuss whether a theory, not using complex numbers, of second order linear differential equations can be developed in introductory calculus courses. In this note we show, utilizing a clever trick by Dobos [2], and expanding it to the real case also, that this indeed is possible by providing a short noncomplex proof of the following well-known:

Theorem. Let $a, b \in \mathbb{R}$. Put $\alpha = a/2$ and $\beta = \sqrt{|a^2/4 - b|}$. All solutions to $y'' + ay' + by = 0$ are given by (1) $y = e^{-\alpha x}(C_1 \cosh(\beta x) + C_2 \sinh(\beta x))$, if $a^2/4 > b$, (2) $y = e^{-\alpha x}(C_1 x + C_2)$, if $a^2/4 = b$, and (3) $y = e^{-\alpha x}(C_1 \cos(\beta x) + C_2 \sin(\beta x))$, if $a^2/4 < b$, for arbitrary $C_1, C_2 \in \mathbb{R}$.

Proof. It is a straightforward calculation to show that the expressions in (1)-(3) are solutions to the differential equation. Now suppose that y is an arbitrary solution the differential equation and put $z = e^{\alpha x}y$. Then $z' = \alpha z + e^{\alpha x}y'$ and thus $z'' = \alpha^2 z + 2\alpha e^{\alpha x}y' + e^{\alpha x}y'' = e^{\alpha x}((a^2/4)y + ay' + y'')$.

(1) Suppose that $a^2/4 > b$. Then $z'' - \beta^2 z = e^{\alpha x}((a^2/4)y + ay' + y'' - (a^2/4 - b)y) = e^{\alpha x}(y'' + ay' + by) = 0$ and hence $(-z \sinh(\beta x) + z' \cosh(\beta x)/\beta)' = 0$ and $(-z' \sinh(\beta x)/\beta + z \cosh(\beta x))' = 0$ which implies that $-z \sinh(\beta x) + z' \cosh(\beta x)/\beta = C_2$ and $-z' \sinh(\beta x)/\beta + z \cosh(\beta x) = C_1$ for some $C_1, C_2 \in \mathbb{R}$. Therefore $C_1 \cosh(\beta x) + C_2 \sinh(\beta x) = z \cosh^2(\beta x) - z \sinh^2(\beta x) = z = e^{\alpha x}y$ and thus finally we get that $y = e^{-\alpha x}z = e^{-\alpha x}(C_1 \cosh(\beta x) + C_2 \sinh(\beta x))$.

(2) Suppose that $a^2/4 = b$. Then $z'' = e^{\alpha x}((a^2/4)y + ay' + y'') = e^{\alpha x}(y'' + ay' + by) = 0$. Hence $z = C_1 x + C_2$ for some $C_1, C_2 \in \mathbb{R}$ and therefore we get that $y = e^{-\alpha x}z = e^{-\alpha x}(C_1 x + C_2)$.

(3) Suppose that $a^2/4 < b$. Then $z'' + \beta^2 z = e^{\alpha x}((a^2/4)y + ay' + y'' + (b - a^2/4)y) = e^{\alpha x}(y'' + ay' + by) = 0$ and hence $(z \sin(\beta x) + z' \cos(\beta x)/\beta)' = 0$ and $(-z' \sin(\beta x)/\beta + z \cos(\beta x))' = 0$ which implies that $z \sin(\beta x) + z' \cos(\beta x)/\beta = C_2$ and $-z' \sin(\beta x)/\beta + z \cos(\beta x) = C_1$ for some $C_1, C_2 \in \mathbb{R}$. Therefore $C_1 \cos(\beta x) + C_2 \sin(\beta x) = z \cos^2(\beta x) + z \sin^2(\beta x) = z = e^{\alpha x}y$ and thus finally we get that $y = e^{-\alpha x}z = e^{-\alpha x}(C_1 \cos(\beta x) + C_2 \sin(\beta x))$. \square

Note that the solutions in (1) above of course easily can be rewritten in the familiar form $y = e^{-\alpha x}(C_1 \cosh(\beta x) + C_2 \sinh(\beta x)) = D_1 e^{r_1 x} + D_2 e^{r_2 x}$ where $D_1 = (C_1 + C_2)/2$, $D_2 = (C_1 - C_2)/2$ and $r_1 = -\alpha + \beta$ and $r_2 = -\alpha - \beta$ are the two roots of the characteristic equation $r^2 + ar + b = 0$.
