

ONE-SCALE H-DISTRIBUTIONS AND VARIANTS

N. ANTONIĆ AND M. ERCEG

ABSTRACT. H-measures and semiclassical (Wigner) measures were introduced in early 1990s and since then they have found numerous applications in problems involving L^2 weakly converging sequences. Although they are similar objects, neither of them is a generalisation of the other, the fundamental difference between them being the fact that semiclassical measures have a characteristic length, while H-measures have none. Recently introduced objects, the one-scale H-measures, generalise both of them, thus encompassing properties of both.

The main aim of this paper is to fully develop this theory to the L^p setting, $p \in (1, \infty)$, by constructing *one-scale H-distributions*, a generalisation of one-scale H-measures and, at the same time, of H-distributions, a generalisation of H-measures to the L^p setting, without any characteristic length. We also address an alternative approach to L^p extension of semiclassical measures via the Wigner transform, introducing new type of objects (semiclassical distributions). Furthermore, we derive a localisation principle in a rather general form, suitable for problems with a characteristic length, as well as those without a specific characteristic length, providing some applications.

1. INTRODUCTION

1.1. Overview of microlocal defect objects. *H-measures* or *microlocal defect measures* were introduced independently by Luc Tartar [61] and Patrick Gérard [32] in early 1990s. They represent a generalisation of defect measures [49] in the sense that, besides the space variables, they depend on the dual variables as well. More precisely, an H-measure is a Radon measure on the cospherical bundle $\Omega \times \mathbb{S}^{d-1} \subseteq T^*\mathbb{R}^d \simeq \mathbb{R}^d \times \mathbb{R}^d$ over a domain $\Omega \subseteq \mathbb{R}^d$, and it is associated to a weakly converging sequence in $L^2_{\text{loc}}(\Omega)$. The main advantage of H-measures over defect measures (and Young measures) can be seen when studying oscillating sequences (the oscillation effects, together with concentration effects, are the typical cause for non-compactness). Indeed, the information about direction of oscillation cannot be captured either by the defect measures or the Young measures, while the H-measures proved to be quite successful for that task.

Let us illustrate this on a simple example of a plain wave:

$$(1.1) \quad u_n(\mathbf{x}) = \varphi(\mathbf{x})e^{2\pi i \frac{\boldsymbol{\xi}}{\varepsilon_n} \cdot \mathbf{k}},$$

where $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$, $\mathbf{k} \in \mathbb{R}^d \setminus \{0\}$, and $\varepsilon_n \rightarrow 0^+$. This sequence weakly converges in $L^2_{\text{loc}}(\mathbb{R}^d)$ to 0 (but not strongly, except in the trivial case $\varphi = 0$). The associated defect measure is the limit of a stationary sequence $|u_n|^2 = |\varphi|^2$ in the space of (unbounded) Radon measures with respect to the weak-* topology. Thus, it is equal to $|\varphi|^2\lambda$, i.e. the measure having density $|\varphi|^2$ with respect to the Lebesgue measure λ on \mathbb{R}^d . Here we can see that the defect measure is independent of the direction of oscillations \mathbf{k} . On the other hand, it can be shown [7, 61] that the H-measure defined by this sequence is

$$(1.2) \quad |\varphi|^2\lambda \otimes \delta_{\frac{\mathbf{k}}{|\mathbf{k}|}},$$

where $|\varphi|^2\lambda$ and $\delta_{\frac{\mathbf{k}}{|\mathbf{k}|}}$ (the Dirac measure at point $\mathbf{k}/|\mathbf{k}|$) are measures in the physical space (variable \mathbf{x}) and the dual space (variable $\boldsymbol{\xi}$), respectively. Hence, the direction of oscillation is inherent in the H-measure.

In the theory of partial differential equations one often deals with weakly converging sequences (see e.g. [28]), allowing H-measures and their (anisotropic) variants to find numerous applications in the field. Let us mention the investigation on propagation of oscillations and on concentration effects in solutions of partial differential equations [4, 11, 23, 41], the applications in the control theory [16, 20, 46], the velocity averaging results [25, 32, 44], the existence of traces and solutions to nonlinear evolution equations [1, 26, 39, 56, 57], as well as explicit formulae and bounds in homogenisation [6, 10, 43, 61]. Most of these applications depend on the so-called localisation principle, which is closely related to the generalisation of compactness by compensation method to variable coefficients [32, 61].

In the example above we can see that the H-measure (1.2) does not distinguish between sequences (1.1) with different frequencies $\frac{1}{\varepsilon_n}$. In order to have such sensitivity we need to incorporate a scale into the definition of microlocal defect objects. That is the case with *semiclassical measures*; the Radon measures on the cotangential bundle $\Omega \times \mathbb{R}^d$ introduced by Gérard [33],

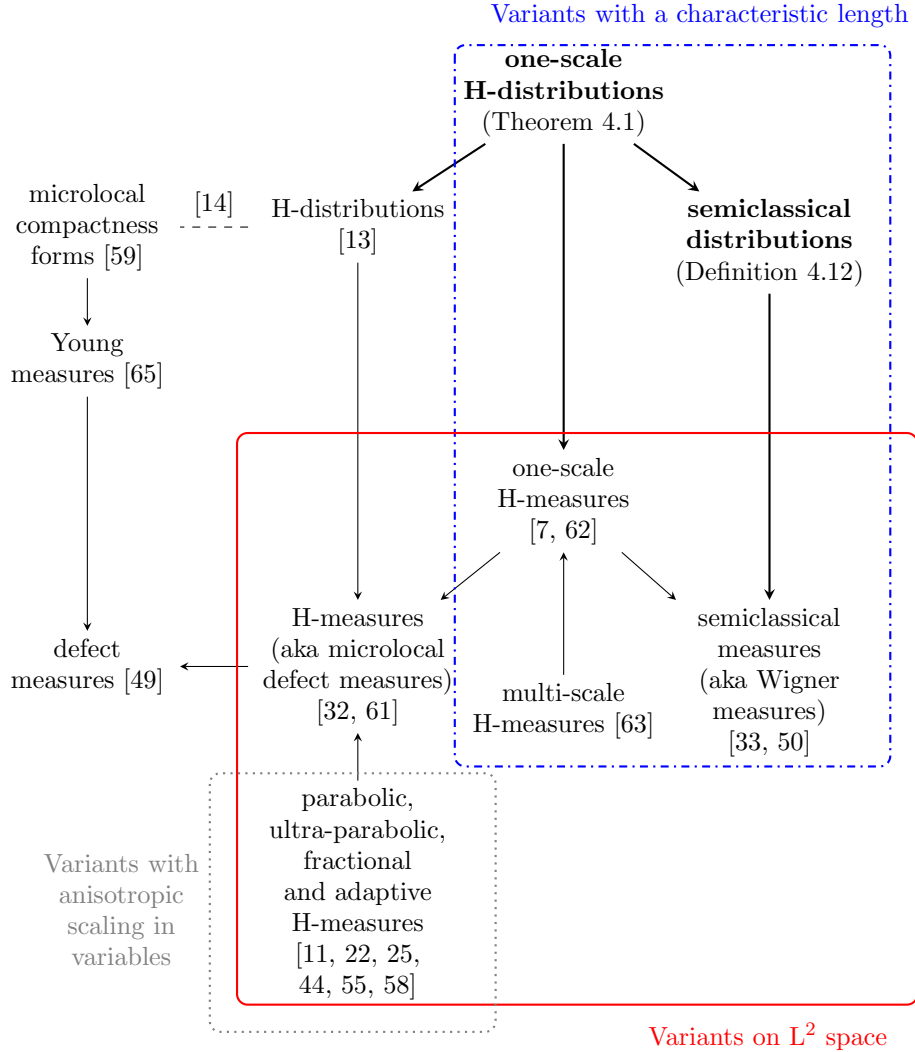

FIGURE 1. Diagram of (microlocal) defect tools of interest. In bold we put new objects that are introduced in this paper. Pointing arrows suggest that the object in the tail is a generalisation of the object in the head of the arrow, while a dashed line means that objects are in a certain relation. For each variant at least one reference is presented (e.g. the first source on the topic or/and later references with a more detailed exposition).

and later baptised *Wigner measures* by Pierre-Louis Lions and Thierry Paul [50]. Since they depend upon a characteristic length (ω_n) , $\omega_n \rightarrow 0^+$ in the real line, they are more suitable in situations where such a characteristic length naturally appears, often related to highly oscillating problems for partial differential equations. Let us just mention the homogenisation limit [35, 50], the microlocal energy density for (semi)linear wave equation [31, 34], the semiclassical limit of Schrödinger equations (propagation of singularities and derivation of effective equations) [18, 19, 30], the mean field limit [3, 48, 53] (for the relation with the bosonic quantum de Finetti theorem see [2, Section 3]), as well as some other problems related to quantum mechanics.

However, the incorporation of a scale into the microlocal defect object as a byproduct brings a new issue. Namely, if the characteristic length (ω_n) of a semiclassical measure is chosen inappropriately, we can lose a significant amount of information. For example, if $\lim_n \frac{\omega_n}{\varepsilon_n} = +\infty$, the semiclassical measure associated to (1.1) is equal to 0 (zero measure). There are examples where this drawback is even more severe (cf. [24, Example 4]). This in particular implies that, in contrast to H-measures, a zero semiclassical measure does not necessarily guarantee the strong convergence of the associated sequence (the so-called (ω_n) -oscillatory property needs to be satisfied as well [35, 24]).

The above discussion shows that H-measures and semiclassical measures are in a general relation (neither is a generalisation of the other) and either has some advantages and disadvantages. Recently, Tartar introduced *one-scale H-measures* [62, Chapter 32] (see also [7, 63]) as a true extension of H-measures and semiclassical measures. Moreover, the localisation principles, both for H-measures and semiclassical measures, can be derived from the localisation principle for one-scale H-measures [7]. The main part in their construction is a proper choice of the domain for dual variables. For a fine tuning with characteristic lengths the set has to be *thick enough*, but we need to allow for directions to be *detected* also at the origin and infinity. This can be achieved with a radial compactification of $\mathbb{R}^d \setminus \{0\}$, denoted by $K_{0,\infty}(\mathbb{R}^d)$, which is homeomorphic to the d -dimensional spherical shell (cf. [7]). Hence, one-scale H-measures are defined on $\Omega \times K_{0,\infty}(\mathbb{R}^d)$.

Heretofore mentioned microlocal defect objects are suitable only for problems expressed in the L^2 framework. In order to overcome this limitation, *H-distributions* were introduced [13], which are an extension of H-measures to the L^p context ($1 < p < \infty$). Due to absence of positivity (which was trivially present in the L^2 setting), H-distributions are in general not measures, but Schwartz' distributions [60]. However, in [8] a more precise description is given through anisotropic distributions. Another approach for studying L^p weakly converging sequences was based on the extension of generalised Young measures obtaining *microlocal compactness forms* [59], which turned out to be closely related to H-distributions [14]. The H-distributions and their variants found their application in developing velocity averaging results [45] and the L^p version of compactness by compensation [13, 54, 59].

In this paper our intention is to close the picture in the L^p setting, as it was already done for $p = 2$ in [7]. More precisely, we shall develop the *one-scale H-distributions* as the L^p counterpart to one-scale H-measures, which, at the same time, generalise H-distributions. Moreover, we can recognise the L^p counterpart of semiclassical measures, the objects which can still be achieved by means of the Wigner transform (see Figure 1). Besides the purely academic motivation to uplift the existing theory to the L^p setting, we hope that these new objects might find more practical applications, like in refining and generalising the procedure of second microlocalisation [29], analysing (semiclassical) wave front sets (cf. [67, chapters 5 and 8], [17]), and studying homogenisation (as well as semiclassical) limits of partial differential equations, all in L^p spaces. For the latter case we emphasise the situation where the nonlinearity in the partial differential equation forces one to work in the L^p framework.

1.2. Notation. Before we proceed, let us briefly recall the notation which we shall use in the paper. For denoting derivatives of (complex) functions defined on \mathbb{R}^d , we use multiindices $\alpha \in \mathbb{N}_0^d$, their length (or 1-norm) being $|\alpha| = \sum \alpha_i$. However, for vectors or points in \mathbb{R}^d we use $|\mathbf{x}| = \sqrt{\mathbf{x} \cdot \mathbf{x}}$ to denote the Euclidean norm (the 2-norm), and similarly on \mathbb{C}^d (where the scalar product is taken to be antilinear in the second variable). In other cases we use subscripts to make precise which (semi)norm we are using. We shall use the projection $\pi(\xi) = \xi/|\xi|$ defined

on $\mathbb{R}_*^d := \mathbb{R}^d \setminus \{0\}$, and taking values on the unit sphere $S^{d-1} \subseteq \mathbb{R}^d$. By $[a]$ we denote the largest integer not greater than $a \in \mathbb{R}$. For a set A , $\text{Cl}A$ denotes its closure, while $\text{Int}A$ its interior (the respective topology will always be clear from the context). In particular, for a subset of complex numbers, this allows \bar{A} to be used for the set of its complex conjugates. The space of $k \times l$ matrices over \mathbb{C} is denoted by $M_{k \times l}(\mathbb{C})$.

By $\hat{u} = \mathcal{F}u$ we shall denote the Fourier transform of u , where for $u \in L^1(\mathbb{R}^d)$ we use the formula: $\hat{u}(\boldsymbol{\xi}) = \int_{\mathbb{R}^d} e^{-2\pi i \mathbf{x} \cdot \boldsymbol{\xi}} u(\mathbf{x}) d\mathbf{x}$. By $\check{u} = \bar{\mathcal{F}}u$ we denote its inverse, while by \mathcal{A}_ψ the Fourier multiplier operator with symbol ψ : $\mathcal{A}_\psi(u) = (\psi \hat{u})^\vee$.

For $p \in [1, \infty]$, by $L_{\text{loc}}^p(\mathbb{R}^d)$ we denote the space of all distributions u such that the following holds

$$(\forall \varphi \in C_c^\infty(\mathbb{R}^d)) \quad \varphi u \in L^p(\mathbb{R}^d).$$

Actually, $C_c^\infty(\mathbb{R}^d)$ can be reduced to \mathcal{G} , its subset such that $(\forall \mathbf{x} \in \mathbb{R}^d)(\exists \varphi \in \mathcal{G}) \text{Re } \varphi(\mathbf{x}) > 0$, which can be chosen to be countable. We endow it with the locally convex topology induced by a family of seminorms $|\cdot|_{\varphi,p}$ (for $\varphi \in \mathcal{G}$)

$$|u|_{\varphi,p} := \|\varphi u\|_{L^p(\mathbb{R}^d)}.$$

It can be shown that neither the definition of $L_{\text{loc}}^p(\mathbb{R}^d)$ nor its topology depend on the choice of family \mathcal{G} with the above property. This definition is equivalent to a definition where one requires that L_{loc}^p functions have finite L^p norms over every compact subset of \mathbb{R}^d (indeed, we can take \mathcal{G} to consist of all characteristic functions χ_K of compacts $K \subseteq \mathbb{R}^d$ and notice that smoothness is not actually needed for the definition of $L_{\text{loc}}^p(\mathbb{R}^d)$ space).

We say that a sequence (u_n) is bounded in $L_{\text{loc}}^p(\mathbb{R}^d)$ if for every seminorm $|\cdot|_{\varphi,p}$ there exists $C_{\varphi,p} > 0$ such that $|u_n|_{\varphi,p} < C_{\varphi,p}$ uniformly in n . By choosing a countable $\mathcal{G} = \{\vartheta_l : l \in \mathbb{N}\}$ such that $0 \leq \vartheta_l \leq 1$ and $\chi_{K_l} \leq \vartheta_l \leq \chi_{K_{l+1}}$, where $K_l := B[0, l] \subseteq \mathbb{R}^d$ is a closed ball of radius l centred around the origin, we can define a metric d_p on $L_{\text{loc}}^p(\mathbb{R}^d)$ by

$$d_p(u, v) := \sup_{l \in \mathbb{N}} 2^{-l} \frac{|u - v|_{\vartheta_l, p}}{1 + |u - v|_{\vartheta_l, p}}.$$

With this metric, $L_{\text{loc}}^p(\mathbb{R}^d)$ is a Fréchet space for each $p \in [1, \infty]$, separable for $p \in [1, \infty)$ and reflexive for $p \in (1, \infty)$. For $p \in [1, \infty)$ it is also valid that $C_c^\infty(\mathbb{R}^d)$ is dense in $L_{\text{loc}}^p(\mathbb{R}^d)$, while $L_c^{p'}(\mathbb{R}^d)$, a subspace of $L^{p'}(\mathbb{R}^d)$ consisting of all functions in that space having a compact support, equipped with the topology of strict inductive limit

$$L_c^{p'}(\mathbb{R}^d) = \bigcup_{l \in \mathbb{N}} L_{K_l}^{p'}(\mathbb{R}^d),$$

is the dual of $L_{\text{loc}}^p(\mathbb{R}^d)$. Of course, we define

$$L_{K_l}^{p'}(\mathbb{R}^d) := \left\{ f \in L^{p'}(\mathbb{R}^d) : \text{supp } f \subseteq K_l \right\} \sim L^{p'}(K_l),$$

and equip it with the $L^{p'}$ norm topology. Let us just remark that we could have replaced \mathbb{R}^d by any open set $\Omega \subseteq \mathbb{R}^d$ and all of the above definitions and conclusions would remain valid. For omitted proofs and further references, we refer the interested reader to [5].

Our last point regarding the notation is that by $\langle \cdot, \cdot \rangle$ we shall denote various duality products, always assuming that it is bilinear. In particular, this means that its relation to the L^2 scalar

product (which we take to be antilinear in the second variable) is as follows

$$\langle f | g \rangle_{L^2} = \int f(\mathbf{x}) \overline{g(\mathbf{x})} d\mathbf{x} = \langle f, \bar{g} \rangle .$$

1.3. Organisation of paper. The second section we start by defining the radial compactification of \mathbb{R}_*^d and then we study smooth functions on it. These results, together with the kernel theorem for anisotropic distributions on manifolds with boundary presented in the third section, are crucial in the construction of one-scale H-distributions, which is conducted in the fourth section. In the rest of the fourth section we study some properties of one-scale H-distributions, and then present two important examples of weakly (but not strongly) converging sequences: the concentration and the oscillation. The section is closed by an alternative construction of semiclassical distributions via the Wigner transform. The last section is devoted to the derivation of the localisation principle suitable for studying differential equations with a characteristic length. The paper is closed by an example illustrating possible applications of the localisation principle.

We would like to mention that a preliminary version of some results presented in this paper appeared as a part of Marko Erceg's Ph.D. thesis [27].

2. SPACE OF TEST FUNCTIONS IN THE DUAL SPACE

2.1. Compactification. In the construction of any microlocal linear functional it is fundamental to carefully specify spaces of test functions, both in the physical and the Fourier (moment or dual) space. In this section we focus on the latter.

For the construction of one-scale H-measures (called *variant of H-measures using a characteristic length* there), Tartar [63, Definition 32.5] chose the space of continuous functions on the suitable compactification of $\mathbb{R}_*^d := \mathbb{R}^d \setminus \{0\}$. More precisely, let $K_{0,\infty}(\mathbb{R}^d)$ be the set obtained by adding two unit spheres, namely Σ_0 and Σ_∞ , to \mathbb{R}_*^d , the first one at the origin and the second one at infinity, equipped with the topology making $K_{0,\infty}(\mathbb{R}^d)$ homeomorphic to a *d-dimensional spherical shell*, as depicted in Figure 2. The points on these two spheres we denote by 0^e and ∞^e , respectively, where $e \in S^{d-1}$ is the (radial) direction of the point (i.e. 0^e and ∞^e are the *endpoints* of a ray passing through e). In the plane, $K_{0,\infty}(\mathbb{R}^2)$ is homeomorphic to the closed annulus.

Since for the construction of one-scale H-distributions we shall need the differential structure on $K_{0,\infty}(\mathbb{R}^d)$ (in order to apply the Hörmander-Mihlin theorem; see Theorem 2.8), we present the compactification above in more detail.

For the compactifying map \mathcal{J} we take the composition of the translation from the origin in the radial direction for $r_0 > 0$:

$$\mathbb{R}_*^d \ni \boldsymbol{\xi} \mapsto \frac{|\boldsymbol{\xi}| + r_0}{|\boldsymbol{\xi}|} \boldsymbol{\xi} \in \mathbb{R}^d \setminus B[0, r_0] ,$$

where $B[0, r_0]$ denotes the closed ball of radius r_0 centred at the origin, and a compactifying map of the radial compactification. Concerning the radial compactification, we shall consider the standard construction obtained by the modified stereographic projection (cf. [51, Chapter 1]), which we briefly sketch here.

We first identify \mathbb{R}^d with the hypersurface $\xi_0 = 1$ in $\mathbb{R}_{\xi_0, \boldsymbol{\xi}}^{1+d}$, and then apply the modified stereographic projection based on the line through the origin (instead of the South Pole). More precisely, the radial compactification map \mathcal{R} maps $\boldsymbol{\xi}$ to the intersection of $[0, 1] \ni t \mapsto (t, t\boldsymbol{\xi})$ (the line through $(1, \boldsymbol{\xi})$ and $(0, 0)$ in \mathbb{R}^{1+d}) and the upper half of the unit sphere centred at

FIGURE 2. Visualisation of $K_{0,\infty}(\mathbb{R}^d)$, the compactification of \mathbb{R}_*^d .

the origin: $S_+^d := \{(\zeta_0, \boldsymbol{\zeta}) \in S^d : \zeta_0 > 0\}$ (see Figure 3 for a visual description). Since the intersection occurs at $t = (1 + |\boldsymbol{\xi}|^2)^{-\frac{1}{2}}$, we have that $\mathcal{R} : \mathbb{R}^d \rightarrow S_+^d$ is given by

$$\mathcal{R}(\boldsymbol{\xi}) = \left(\frac{1}{\sqrt{1 + |\boldsymbol{\xi}|^2}}, \frac{\boldsymbol{\xi}}{\sqrt{1 + |\boldsymbol{\xi}|^2}} \right).$$

FIGURE 3. On the left there is a graphical description of the mapping \mathcal{J} for $r_0 = 1$, where $S_{(0,r_1)}^d$ is denoted in blue, while a visualisation of $S_{(0,r_1)}^d$ in space is given on the right.

Finally, let us define $\mathcal{J} := \mathcal{R} \circ \mathcal{T}$. Since

$$\mathcal{R}(\mathbb{R}^d \setminus B[0, r_0]) = \left\{ (\zeta_0, \boldsymbol{\zeta}) \in S^d : 0 < \zeta_0 < r_1 \right\} =: S_{(0,r_1)}^d,$$

where $r_1 := (1 + r_0^2)^{-1/2}$, we have that $\mathcal{J} : \mathbb{R}_*^d \rightarrow S_{(0,r_1)}^d$ and has the explicit expression

$$(2.1) \quad \mathcal{J}(\boldsymbol{\xi}) = \left(\frac{1}{\sqrt{1 + (|\boldsymbol{\xi}| + r_0)^2}}, \frac{|\boldsymbol{\xi}| + r_0}{\sqrt{1 + (|\boldsymbol{\xi}| + r_0)^2}} \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|} \right).$$

Here on $S_{(0,r_1)}^d$ we consider the topology inherited from \mathbb{R}^{1+d} , thus

$$(2.2) \quad \text{Cl } S_{(0,r_1)}^d = \left\{ (\zeta_0, \zeta) \in S^d : 0 \leq \zeta_0 \leq r_1 \right\} =: S_{[0,r_1]}^d$$

is a compact set. Furthermore, \mathcal{J} is a C^∞ -diffeomorphism (thus a homeomorphism as well), and its inverse $\mathcal{J}^{-1} : S_{(0,r_1)}^d \rightarrow \mathbb{R}_*^d$ is given by

$$\mathcal{J}^{-1}(\zeta_0, \zeta) = \frac{\zeta}{\zeta_0} - r_0 \frac{\zeta}{|\zeta|}.$$

Therefore, $(S_{[0,r_1]}^d, \mathcal{J})$ is a compactification of \mathbb{R}_*^d .

For future reference we introduce the following notation:

$$(2.3) \quad S_I^d := \left\{ (\zeta_0, \zeta) \in S^d : \zeta_0 \in I \right\},$$

where $I \subseteq [0, 1]$, and the shorthand $S_a^d := S_{\{a\}}^d$. It is obvious that boundaries of $S_{[0,r_1]}^d$ are given by $S_{r_1}^d$ and S_0^d .

As we have already hinted at above, we define

$$\Sigma_0 := \{0^e : e \in S^{d-1}\} \quad \text{and} \quad \Sigma_\infty := \{\infty^e : e \in S^{d-1}\},$$

and then we take (a disjoint union) $K_{0,\infty}(\mathbb{R}^d) := \mathbb{R}_*^d \dot{\cup} \Sigma_0 \dot{\cup} \Sigma_\infty$ (see Figure 2). Since the mapping

$$[0, +\infty) \ni x \mapsto \frac{1}{\sqrt{1 + (x + r_0)^2}}$$

is strictly decreasing, it is easy to see that for any sequence (ξ_n) in \mathbb{R}_*^d we have

$$\begin{aligned} \lim_n \left| \mathcal{J}(\xi_n) - \left(r_1, r_0 r_1 \frac{\xi_n}{|\xi_n|} \right) \right| = 0 &\iff \lim_n |\xi_n| = 0, \\ \lim_n \left| \mathcal{J}(\xi_n) - \left(0, \frac{\xi_n}{|\xi_n|} \right) \right| = 0 &\iff \lim_n |\xi_n| = +\infty. \end{aligned}$$

Hence, we can extend \mathcal{J} to $K_{0,\infty}(\mathbb{R}^d)$ (and consequently also \mathcal{J}^{-1} to $S_{[0,r_1]}^d$) by defining $\mathcal{J}(0^e) := (r_1, r_0 r_1 e)$ and $\mathcal{J}(\infty^e) := (0, e)$, implying that $\mathcal{J}(\Sigma_0) = S_{r_1}^d$ and $\mathcal{J}(\Sigma_\infty) = S_0^d$ (although the notation for the boundaries of $S_{[0,r_1]}^d$ we found natural, one needs to be careful here as the sphere at infinity is mapped to S_0^d).

Remark 2.1. The choice of $r_0 > 0$ is completely irrelevant as long as we keep it fixed, which is the case in the paper. Of course, for $r_0 = 0$ one can notice that we would have $\mathcal{J} = \mathcal{R}$, i.e. $K_{0,\infty}(\mathbb{R}^d)$ would just be the standard radial compactification of \mathbb{R}^d .

2.2. Smooth test functions. Now we can define a metric on the compactification $K_{0,\infty}(\mathbb{R}^d)$ by pulling back the euclidean metric on $S_{[0,r_1]}^d$, i.e.

$$d_{K_{0,\infty}(\mathbb{R}^d)}(\xi_1, \xi_2) := |\mathcal{J}(\xi_1) - \mathcal{J}(\xi_2)|.$$

This allows us to define continuous functions on $K_{0,\infty}(\mathbb{R}^d)$, and it can easily be seen that $\psi \in C(K_{0,\infty}(\mathbb{R}^d))$ if and only if $\psi \circ \mathcal{J}^{-1} \in C(S_{[0,r_1]}^d)$. A common way for defining the space of smooth functions is by generalising the latter characterisation: for $\kappa \in \mathbb{N}_0 \cup \{\infty\}$ we define

$$C^\kappa(K_{0,\infty}(\mathbb{R}^d)) := \left\{ \psi \in C(K_{0,\infty}(\mathbb{R}^d)) : \psi^* := (\mathcal{J}^{-1})^* \psi = \psi \circ \mathcal{J}^{-1} \in C^\kappa(S_{[0,r_1]}^d) \right\},$$

where $C^\kappa(S_{[0,r_1]}^d)$ is the space of functions which can be extended to a C^κ function on some open neighbourhood of $S_{[0,r_1]}^d$. Moreover, with this definition $K_{0,\infty}(\mathbb{R}^d)$ is equipped with a unique smooth structure such that \mathcal{J} is a *smooth covering map* (cf. [47, Chapter 4]). For simplicity, we shall often denote by $\psi^* := \psi \circ \mathcal{J}^{-1}$ the pullback of function $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ along \mathcal{J}^{-1} .

Since $\mathcal{J} : \mathbb{R}_*^d \rightarrow S_{(0,r_1)}^d$ is a diffeomorphism, the restriction to \mathbb{R}_*^d of any function from the space $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ is a function of class C^κ .

For $\kappa \neq \infty$ and $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ we define $\|\psi\|_{C^\kappa(K_{0,\infty}(\mathbb{R}^d))} := \|\psi^*\|_{C^\kappa(S_{[0,r_1]}^d)}$. Since $C^\kappa(S_{[0,r_1]}^d)$ is a Banach algebra, under this definition $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ is also a Banach algebra. Moreover, by the compactness of $S_{[0,r_1]}^d$, the space $C^\kappa(S_{[0,r_1]}^d)$ is separable, implying that $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ is separable as well. In the case $\kappa = \infty$ we get a Fréchet space by taking a monotone sequence of norms $(\|\cdot\|_{C^n(K_{0,\infty}(\mathbb{R}^d))})_n$.

As it was commented above, any C^κ function on $K_{0,\infty}(\mathbb{R}^d)$ is in fact of class C^κ on \mathbb{R}_*^d (in the sense of the restriction to \mathbb{R}_*^d). In the following we study under which additional conditions the converse holds as well, i.e. when a function in $C^\kappa(\mathbb{R}_*^d)$ can be extended to a function in $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$. Of course, if such extension exists, it is unique (since \mathbb{R}_*^d is dense in $K_{0,\infty}(\mathbb{R}^d)$). In the rest of the paper we use this identification of $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ as a subset of $C^\kappa(\mathbb{R}_*^d)$.

Obviously, it is crucial to examine the behaviour of functions around zero and at infinity, i.e. in neighbourhoods of Σ_0 and Σ_∞ . A neighbourhood of Σ_0 can be identified with the product $[0, 1) \times S^{d-1}$ using the variables $|\xi|, \frac{\xi}{|\xi|}$. Indeed, it is sufficient to see that

$$(2.4) \quad \mathcal{J} \circ \mathcal{J}_0^{-1} : [0, 1) \times S^{d-1} \longrightarrow S_{((1+(1+r_0)^2)^{-1/2}, r_1]}^d$$

is a C^∞ -diffeomorphism, where $\mathcal{J}_0(\xi) := (|\xi|, \frac{\xi}{|\xi|})$. Since $\mathcal{J}_0^{-1}(s, \eta) = s\eta$ we have

$$(\mathcal{J} \circ \mathcal{J}_0^{-1})(s, \eta) = \left(\frac{1}{\sqrt{1+(s+r_0)^2}}, \frac{s+r_0}{\sqrt{1+(s+r_0)^2}} \eta \right),$$

which is obviously a smooth bijection from $[0, 1) \times S^{d-1}$ to $S_{((1+(1+r_0)^2)^{-1/2}, r_1]}^d$. Its inverse is smooth as well since

$$(\mathcal{J}_0 \circ \mathcal{J}^{-1})(\zeta_0, \zeta) = \left(\frac{|\zeta|}{\zeta_0} - r_0, \frac{\zeta}{|\zeta|} \right)$$

and on its domain we have $\zeta_0 > \frac{1}{\sqrt{1+(1+r_0)^2}} > 0$ and $|\zeta| > r_0 r_1 > 0$.

Analogously, for $\mathcal{J}_\infty(\xi) := (\frac{1}{|\xi|}, \frac{\xi}{|\xi|})$ the mapping

$$(2.5) \quad \mathcal{J} \circ \mathcal{J}_\infty^{-1} : [0, 1) \times S^{d-1} \longrightarrow S_{[0, (1+(1+r_0)^2)^{-1/2}]}^d$$

is a C^∞ -diffeomorphism. Thus, a neighbourhood of Σ_∞ can be identified with the product $[0, 1) \times S^{d-1}$ using the variables $\frac{1}{|\xi|}, \frac{\xi}{|\xi|}$.

Now we can prove the following important lemma.

Lemma 2.2. *Let $\kappa \in \mathbb{N}_0 \cup \{\infty\}$. The following two statements are equivalent:*

- i) $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$;

ii) $\psi \in C^\kappa(\mathbb{R}_*^d)$ and there exist $\tilde{\psi}_0, \tilde{\psi}_\infty \in C^\kappa([0, 1) \times \mathbb{S}^{d-1})$ such that

$$(2.6) \quad \psi(\boldsymbol{\xi}) = \tilde{\psi}_0\left(|\boldsymbol{\xi}|, \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right), \quad 0 < |\boldsymbol{\xi}| < 1,$$

$$(2.7) \quad \psi(\boldsymbol{\xi}) = \tilde{\psi}_\infty\left(\frac{1}{|\boldsymbol{\xi}|}, \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right), \quad |\boldsymbol{\xi}| > 1.$$

Proof. Let $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$. Then $\psi \in C^\kappa(\mathbb{R}_*^d)$ and there exists $\psi^* \in C^\kappa(\mathbb{S}_{[0,r_1]}^d)$ such that $\psi = \psi^* \circ \mathcal{J}$. Since mappings (2.4) and (2.5) are smooth, we have that functions $\tilde{\psi}_0 := \psi^* \circ \mathcal{J} \circ \mathcal{J}_0^{-1}$ and $\tilde{\psi}_\infty := \psi^* \circ \mathcal{J} \circ \mathcal{J}_\infty^{-1}$ are in $C^\kappa([0, 1) \times \mathbb{S}^{d-1})$. Moreover, $\tilde{\psi}_0(|\boldsymbol{\xi}|, \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}) = \tilde{\psi}_0(\mathcal{J}_0(\boldsymbol{\xi})) = \psi^*(\mathcal{J}(\boldsymbol{\xi})) = \psi(\boldsymbol{\xi})$, and analogously for $\tilde{\psi}_\infty$.

Assume now that condition (ii) is fulfilled, and let us prove that $\psi \circ \mathcal{J}^{-1} \in C^\kappa(\mathbb{S}_{[0,r_1]}^d)$. Since \mathcal{J} is smooth from \mathbb{R}_*^d to $\mathbb{S}_{(0,r_1)}^d$, we obviously have $\psi \circ \mathcal{J}^{-1} \in C^\kappa(\mathbb{S}_{(0,r_1)}^d)$. Thus, it remains to prove the smoothness on a neighbourhood of the boundary. As the mapping (2.4) is smooth, we have that function $\tilde{\psi}_0 \circ (\mathcal{J}_0 \circ \mathcal{J}^{-1})$ is of class C^κ on $\mathbb{S}_{((1+(1+r_0)^2)^{-1/2}, r_1]}^d$. Furthermore, by (2.6), the functions $\psi \circ \mathcal{J}^{-1}$ and $\tilde{\psi}_0 \circ (\mathcal{J}_0 \circ \mathcal{J}^{-1})$ coincide on $\mathbb{S}_{((1+(1+r_0)^2)^{-1/2}, r_1]}^d$, hence $\psi \circ \mathcal{J}^{-1}$ is smooth up to the boundary $\mathbb{S}_{r_1}^d$. Smoothness on a neighbourhood of \mathbb{S}_0^d can be obtained in an analogous way by using the smoothness of (2.5) and condition (2.7). \square

If in addition ψ is smooth up to the origin, i.e. $\psi \in C^\kappa(\mathbb{R}^d)$, then the function $\tilde{\psi}(s, \boldsymbol{\eta}) := \psi(s\boldsymbol{\eta})$ is smooth on $[0, 1) \times \mathbb{S}^{d-1}$ and trivially satisfies (2.6). Thus, we have the following corollary.

Corollary 2.3. *Let $\psi \in C^\kappa(\mathbb{R}^d)$ and let $\tilde{\psi}_\infty \in C^\kappa([0, 1) \times \mathbb{S}^{d-1})$ satisfy (2.7). Then $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$.*

The statement of Lemma 2.2 simplifies for $\kappa = 0$ as follows.

Corollary 2.4. *Let $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$. Then there exist unique functions $\psi_0, \psi_\infty \in C^\kappa(\mathbb{S}^{d-1})$ such that*

$$(2.8) \quad \begin{aligned} \psi(\boldsymbol{\xi}) - \psi_0\left(\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right) &\longrightarrow 0, \quad |\boldsymbol{\xi}| \rightarrow 0, \\ \psi(\boldsymbol{\xi}) - \psi_\infty\left(\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right) &\longrightarrow 0, \quad |\boldsymbol{\xi}| \rightarrow \infty. \end{aligned}$$

Furthermore, if for $\psi \in C(\mathbb{R}_*^d)$ there exist $\psi_0, \psi_\infty \in C(\mathbb{S}^{d-1})$ such that (2.8) holds, then $\psi \in C(K_{0,\infty}(\mathbb{R}^d))$.

Proof. The uniqueness of functions ψ_0 and ψ_∞ trivially follows from (2.8).

For the existence, take $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$. Then by the previous lemma there exist $\tilde{\psi}_0, \tilde{\psi}_\infty \in C^\kappa([0, 1) \times \mathbb{S}^{d-1})$ such that (2.6)–(2.7) hold. For $\boldsymbol{\eta} \in \mathbb{S}^{d-1}$ we define $\psi_0(\boldsymbol{\eta}) := \tilde{\psi}_0(0, \boldsymbol{\eta})$ and $\psi_\infty(\boldsymbol{\eta}) := \tilde{\psi}_\infty(0, \boldsymbol{\eta})$, which are obviously functions contained in $C^\kappa(\mathbb{S}^{d-1})$. Relations (2.8) now follow by (2.6)–(2.7) and uniform continuity of functions $\tilde{\psi}_0$ and $\tilde{\psi}_\infty$ on $[0, 1/2] \times \mathbb{S}^{d-1}$.

The second part holds by Lemma 2.2, once it is noted that functions

$$\tilde{\psi}_0(s, \boldsymbol{\eta}) := \begin{cases} \psi_0(\boldsymbol{\eta}), & s = 0, \boldsymbol{\eta} \in \mathbb{S}^{d-1} \\ \psi(s\boldsymbol{\eta}), & s \in (0, 1), \boldsymbol{\eta} \in \mathbb{S}^{d-1} \end{cases}, \quad \tilde{\psi}_\infty(s, \boldsymbol{\eta}) := \begin{cases} \psi_\infty(\boldsymbol{\eta}), & s = 0, \boldsymbol{\eta} \in \mathbb{S}^{d-1} \\ \psi(\frac{\boldsymbol{\eta}}{s}), & s \in (0, 1), \boldsymbol{\eta} \in \mathbb{S}^{d-1} \end{cases}$$

are continuous on $[0, 1) \times \mathbb{S}^{d-1}$. \square

The characterisation of the space of continuous functions on $K_{0,\infty}(\mathbb{R}^d)$ from the previous corollary can easily be derived directly, with no reference to Lemma 2.2, which was the case in [62, Definition 32.5] (see also [7]). Unfortunately, this characterisation cannot be generalised to the case $\kappa \geq 1$ since smoothness of functions ψ_0 and ψ_∞ is not sufficient to ensure the required smoothness of functions $\tilde{\psi}_0$ and $\tilde{\psi}_\infty$, defined in the proof of the corollary. Indeed, in order to smoothly extend a function to the boundary, besides knowledge of tangential derivatives, one needs some information on the normal derivative as well.

In the rest of the paper we shall, for an arbitrary $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$, denote by ψ_0 and ψ_∞ the functions defined by (2.8), i.e. the restrictions of ψ to Σ_0 and Σ_∞ respectively.

Let us see how we can estimate the norm of $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$. By Lemma 2.2 we have that the equality $\tilde{\psi}_0 \circ (\mathcal{J}_0 \circ \mathcal{J}^{-1}) = \psi \circ \mathcal{J}^{-1}$ holds on $S^d_{[(1+(1/2+r_0)^2)^{-1/2}, r_1]}$. Since $\mathcal{J}_0 \circ \mathcal{J}^{-1}$ is a C^∞ -diffeomorphism on that compact set, this function and all its derivatives are bounded. Now we apply the generalised chain rule formula, known under the name *Faá di Bruno formula* (see e.g. [38]): *For sufficiently smooth functions $g : \mathbb{R}^d \rightarrow \mathbb{R}^r$ and $f : \mathbb{R}^r \rightarrow \mathbb{R}$ one has*

$$(2.9) \quad \partial^\alpha (f \circ g)(\xi) = |\alpha|! \sum_{\substack{\beta \in \mathbb{N}_0^r, \\ 1 \leq |\beta| \leq |\alpha|}} C(\beta, \alpha),$$

where

$$C(\beta, \alpha) = \frac{(\partial^\beta f)(g(\xi))}{\beta!} \sum_{\substack{\alpha_i \in \mathbb{N}_0^d, \\ \sum_{i=1}^r \alpha_i = \alpha}} \prod_{j=1}^r \sum_{\substack{\gamma_i \in \mathbb{N}_0^d \setminus \{0\}, \\ \sum_{i=1}^{\beta_j} \gamma_i = \alpha_j}} \prod_{s=1}^{\beta_j} \frac{\partial^{\gamma_s} g_j(\xi)}{\gamma_s!}.$$

Therefore, there exists a constant $C_\kappa > 0$ depending only on κ such that

$$\begin{aligned} \|\psi \circ \mathcal{J}^{-1}\|_{C^\kappa(S^d_{[(1+(1/2+r_0)^2)^{-1/2}, r_1]})} &= \|\tilde{\psi}_0 \circ (\mathcal{J}_0 \circ \mathcal{J}^{-1})\|_{C^\kappa(S^d_{[(1+(1/2+r_0)^2)^{-1/2}, r_1]})} \\ &\leq C_\kappa \|\tilde{\psi}_0\|_{C^\kappa([0, \frac{1}{2}] \times S^{d-1})}. \end{aligned}$$

Applying the same reasoning on $\tilde{\psi}_0 = (\psi \circ \mathcal{J}^{-1}) \circ (\mathcal{J} \circ \mathcal{J}_0^{-1})$ we get

$$\begin{aligned} \|\psi\|_{C^\kappa(K_{0,\infty}(\mathbb{R}^d))} &= \|\psi \circ \mathcal{J}^{-1}\|_{C^\kappa(S^d_{[0, r_1]})} \\ &\geq \|\psi \circ \mathcal{J}^{-1}\|_{C^\kappa(S^d_{[(1+(1/2+r_0)^2)^{-1/2}, r_1]})} \geq c_\kappa \|\tilde{\psi}_0\|_{C^\kappa([0, \frac{1}{2}] \times S^{d-1})}. \end{aligned}$$

Completely analogous estimates could be derived on $S^d_{[(1+(1/2+r_0)^2)^{-1/2}, r_1]}$ for $\tilde{\psi}_\infty$. Finally, since \mathcal{J} is a C^∞ -diffeomorphism on the compact $\{\xi \in \mathbb{R}^d : \frac{1}{4} \leq |\xi| \leq 4\}$, we can estimate the norm of $\psi \circ \mathcal{J}^{-1}$ on $S^d_{[(1+(4+r_0)^2)^{-1/2}, (1+(1/4+r_0)^2)^{-1/2}]}$ (both from below and above) by the norm of ψ on $\{\xi \in \mathbb{R}^d : \frac{1}{4} \leq |\xi| \leq 4\}$ (up to a multiplicative constant).

The overall conclusion we give in the form of a lemma.

Lemma 2.5. *For any $\kappa \in \mathbb{N}_0$ there exist constants $c_\kappa, C_\kappa > 0$, depending only on κ , such that for any $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ it holds*

$$\begin{aligned} &c_\kappa \max\{\|\tilde{\psi}_0\|_{C^\kappa([0, \frac{1}{2}] \times S^{d-1})}, \|\psi\|_{C^\kappa(\{\xi \in \mathbb{R}^d : \frac{1}{4} \leq |\xi| \leq 4\})}, \|\tilde{\psi}_\infty\|_{C^\kappa([0, 2] \times S^{d-1})}\} \\ &\leq \|\psi\|_{C^\kappa(K_{0,\infty}(\mathbb{R}^d))} \\ &\leq C_\kappa \max\{\|\tilde{\psi}_0\|_{C^\kappa([0, \frac{1}{2}] \times S^{d-1})}, \|\psi\|_{C^\kappa(\{\xi \in \mathbb{R}^d : \frac{1}{4} \leq |\xi| \leq 4\})}, \|\tilde{\psi}_\infty\|_{C^\kappa([0, 2] \times S^{d-1})}\}, \end{aligned}$$

where functions $\tilde{\psi}_0$ and $\tilde{\psi}_\infty$ are given by (2.6)–(2.7).

Let us now present some examples of functions inhabiting the space $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$.

Corollary 2.6. *Let $\pi(\boldsymbol{\xi}) := \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}$ be the projection of \mathbb{R}_*^d along rays through origin to the unit sphere S^{d-1} . Then the following statements hold:*

- i) $\{\psi \circ \pi : \psi \in C^\kappa(S^{d-1})\} \subseteq C^\kappa(K_{0,\infty}(\mathbb{R}^d))$, $\kappa \in \mathbb{N}_0 \cup \{\infty\}$,
- ii) $\mathcal{S}(\mathbb{R}^d) \subseteq C^\infty(K_{0,\infty}(\mathbb{R}^d))$,
- iii) $(\forall m, l \in \mathbb{N}_0)(\forall \boldsymbol{\alpha} \in \mathbb{N}_0^d) \quad l \leq |\boldsymbol{\alpha}| \leq m \implies \boldsymbol{\xi} \mapsto \frac{\boldsymbol{\xi}^\alpha}{|\boldsymbol{\xi}|^l + |\boldsymbol{\xi}|^m} \in C^\infty(K_{0,\infty}(\mathbb{R}^d))$, and
- iv) $(\forall m \in \mathbb{N}) \quad \boldsymbol{\xi} \mapsto \frac{1 + |\boldsymbol{\xi}|^m}{(1 + |\boldsymbol{\xi}|^2)^{\frac{m}{2}}}$, $\boldsymbol{\xi} \mapsto \frac{(1 + |\boldsymbol{\xi}|^2)^{\frac{m}{2}}}{1 + |\boldsymbol{\xi}|^m} \in C^\infty(K_{0,\infty}(\mathbb{R}^d))$.

Proof. (i) For any $\psi \in C^\kappa(S^{d-1})$ the function $\boldsymbol{\xi} \mapsto \psi(\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|})$ trivially satisfies conditions of the second part of Lemma 2.2 with $\tilde{\psi}_0(s, \boldsymbol{\eta}) = \tilde{\psi}_\infty(s, \boldsymbol{\eta}) = \psi(\boldsymbol{\eta})$, for $(s, \boldsymbol{\eta}) \in [0, 1) \times S^{d-1}$, i.e. $\psi_0 = \psi_\infty = \psi$.

(ii) By Corollary 2.3 we only have to show the existence of $\tilde{\psi}_\infty$. Let $\psi \in \mathcal{S}(\mathbb{R}^d)$ and let us define $\tilde{\psi}_\infty(s, \boldsymbol{\eta}) := \psi(\frac{\boldsymbol{\eta}}{s})$, for $(s, \boldsymbol{\eta}) \in (0, 1) \times S^{d-1}$. It is obvious that $\tilde{\psi}_\infty \in C^\infty((0, 1) \times S^{d-1})$ and that (2.7) is satisfied. Hence, it remains to be proven that $\tilde{\psi}_\infty$ and all its derivatives can be extended by continuity on $s = 0$. This holds since ψ is a rapidly decreasing function and for an arbitrary $\boldsymbol{\alpha} \in \mathbb{N}_0^d$ we have $\partial^\alpha \tilde{\psi}(s, \boldsymbol{\eta}) = (\partial^\alpha \psi)(\frac{\boldsymbol{\eta}}{s}) P_\alpha(\frac{1}{s}, \boldsymbol{\eta})$, where P_α is a polynomial (in $1 + d$ variables). Therefore, by letting $\partial^\alpha \tilde{\psi}_\infty(0, \boldsymbol{\eta}) := 0$, $\boldsymbol{\alpha} \in \mathbb{N}_0^d$, $\boldsymbol{\eta} \in S^{d-1}$, we get that $\tilde{\psi}_\infty$ is smooth up to the boundary $s = 0$.

(iii) Since $\frac{\boldsymbol{\xi}^\alpha}{|\boldsymbol{\xi}|^l + |\boldsymbol{\xi}|^m} = \frac{\boldsymbol{\xi}^\alpha}{|\boldsymbol{\xi}|^{|\alpha|}} \frac{|\boldsymbol{\xi}|^{|\alpha| - l}}{1 + |\boldsymbol{\xi}|^{m-l}}$ and $C^\infty(K_{0,\infty}(\mathbb{R}^d))$ is an algebra, by part (i) it is sufficient to prove that for any $m, k \in \mathbb{N}_0$, $k \leq m$, the function $\psi^{m,k}(\boldsymbol{\xi}) = \frac{|\boldsymbol{\xi}|^k}{1 + |\boldsymbol{\xi}|^m}$ is contained in $C^\infty(K_{0,\infty}(\mathbb{R}^d))$. Let us now check the conditions of Lemma 2.2(ii).

It is evident that $\psi^{m,k}$ is smooth on \mathbb{R}_*^d . Moreover, since

$$\psi^{m,k}(\boldsymbol{\xi}) = \frac{|\boldsymbol{\xi}|^k}{1 + |\boldsymbol{\xi}|^m} = \frac{(\frac{1}{|\boldsymbol{\xi}|})^{m-k}}{(\frac{1}{|\boldsymbol{\xi}|})^m + 1}, \quad \boldsymbol{\xi} \in \mathbb{R}_*^d,$$

the functions $\tilde{\psi}_0^{m,k}(s, \boldsymbol{\eta}) = \frac{s^k}{1 + s^m}$ and $\tilde{\psi}_\infty(s, \boldsymbol{\eta}) = \frac{s^{m-k}}{s^m + 1}$ satisfy (2.6)–(2.7), and they are clearly smooth on $[0, 1) \times S^{d-1}$. Thus, by Lemma 2.2 we have that $\psi^{m,k} \in C^\infty(K_{0,\infty}(\mathbb{R}^d))$.

(iv) By Lemma 2.2 the statements trivially holds, following the same argument as in part (iii). Let us just remark that it is sufficient to prove the statement only for one function after noting that it is strictly positive (hence we can conclude that its multiplicative inverse is in $C^\infty(K_{0,\infty}(\mathbb{R}^d))$ as well). \square

Remark 2.7.

- i) The compactification $K_{0,\infty}(\mathbb{R}^d)$ could be seen as the blow-up at 0 of the radial compactification of \mathbb{R}^d , or the blow-up at 0 and ∞ of the one-point compactification of \mathbb{R}^d (see e.g. [51, Section 1+.5]). If we denote the radial compactification by $K_\infty(\mathbb{R}^d)$ (this notation was used in [62, Definition 32.5]), this means that the mapping $\mathcal{I} : K_{0,\infty}(\mathbb{R}^d) \rightarrow K_\infty(\mathbb{R}^d)$ given by

$$\mathcal{I}(\boldsymbol{\xi}) = \begin{cases} \mathbf{x}, & \mathbf{x} \notin \Sigma_0 \\ 0, & \mathbf{x} \in \Sigma_0 \end{cases}$$

is smooth. In particular, all smooth functions on the radial compactification are smooth on $K_{0,\infty}(\mathbb{R}^d)$, which in fact we have already shown in Corollary 2.3 (in [51, Chapter 1] the smooth functions on the radial compactification are characterised precisely by the assumptions given in the corollary).

- ii) Instead of (2.1), for the compactifying map in [27, Section II.1] the projection on the last d variables of $\mathcal{J}(\boldsymbol{\xi})$ was taken. That choice corresponds to a generalisation of the quadratic compactification (see e.g. [51, (L1.11)]; for $r_0 = 0$ it is precisely the quadratic compactification). These two compactifications are not equivalent since the inverse of the projection of the upper half-sphere to the ball has a square-root singularity [51, Chapter 1], thus in [27, Section III.2] a smaller space of smooth functions was obtained. In particular, the function $\boldsymbol{\xi} \mapsto (1 + |\boldsymbol{\xi}|^2)^{-\frac{1}{2}}$ is not smooth with that choice, which caused some problems in deriving the localisation principle [27, Section III.5].
- iii) The idea of studying functions on a compactified space could be seen as a way of controlling functions at infinity [51] (in our case of $K_{0,\infty}(\mathbb{R}^d)$ at the origin as well; see (2.11) below). Thus, with this approach the standard growth conditions of (pseudodifferential) symbols could be set intrinsically by a suitable choice of compactification, which is a known approach in the literature.

2.3. Symbols of Fourier multipliers. In the construction of one-scale H-distributions we shall need that test functions on the dual space are *Fourier multipliers*: for $\psi \in L^\infty(\mathbb{R}^d)$ we say that it is an L^p , $p \in (1, \infty)$, Fourier multiplier if $\mathcal{A}_\psi u := (\psi \hat{u})^\vee$ is continuous on $L^p(\mathbb{R}^d; \mathbb{C}^r)$ [36, Section 2.5].

Therefore, we want to show that there exists κ such that for any $p \in (1, \infty)$ all functions from $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ are L^p Fourier multipliers (in the sense of the corresponding restrictions to \mathbb{R}_*^d). In the case $p = 2$ this is trivially satisfied (see [36, Theorem 2.5.10]) since continuous functions on $K_{0,\infty}(\mathbb{R}^d)$ are bounded. However, for $p \neq 2$ the complete answer to the question of characterising L^p Fourier multipliers is still open. Thus, one relies on a few available criteria providing sufficient conditions. Here we shall use the Mihlin condition [36, Theorem 5.2.7] (note that $\lfloor r \rfloor$ denotes the greatest integer less than or equal to real r).

Theorem 2.8. *Let $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{R}_*^d)$ be a bounded function. Assume that there exists $C > 0$ such that for any $\boldsymbol{\alpha} \in \mathbb{N}_0^d$, $|\boldsymbol{\alpha}| \leq \lfloor \frac{d}{2} \rfloor + 1$, it holds*

$$(2.10) \quad |\partial^{\boldsymbol{\alpha}} \psi(\boldsymbol{\xi})| \leq \frac{C}{|\boldsymbol{\xi}|^{|\boldsymbol{\alpha}|}}, \quad \boldsymbol{\xi} \in \mathbb{R}_*^d.$$

Then for any $p \in (1, \infty)$ the function ψ is an L^p Fourier multiplier and the operator norm of \mathcal{A}_ψ satisfies

$$\|\mathcal{A}\|_{\mathcal{L}(L^p(\mathbb{R}^d))} \leq C_{d,p} C,$$

where $C_{d,p}$ is a constant depending only on d and p , while C is the constant appearing in (2.10).

Now we finally prove the main result of this section.

Theorem 2.9. *Any function from $C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$ satisfies Mihlin's condition (2.10).*

In particular, for any $p \in (1, \infty)$, it holds

$$\|\mathcal{A}_\psi\|_{\mathcal{L}(L^p(\mathbb{R}^d))} \leq C_{d,p} C_d \|\psi\|_{C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))}, \quad \psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d)),$$

where $C_{d,p}$ is the constant from Theorem 2.8, and C_d is a constant depending only on d .

Proof. Let $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$. By Theorem 2.8 it is sufficient to prove

$$(2.11) \quad |\partial^\alpha \psi(\boldsymbol{\xi})| \leq \frac{C_d \|\psi\|_{C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))}}{|\boldsymbol{\xi}|^{|\alpha|}}, \quad \boldsymbol{\xi} \in \mathbb{R}_*^d,$$

for any $|\alpha| \leq \lfloor \frac{d}{2} \rfloor + 1$.

Let us consider first $\boldsymbol{\xi} \in \mathbb{R}_*^d$ such that $\frac{1}{4} \leq |\boldsymbol{\xi}| \leq 4$. Since this set is compact and both functions $\partial^\alpha \psi$ and $\boldsymbol{\xi} \mapsto \frac{1}{|\boldsymbol{\xi}|^{|\alpha|}}$ are continuous on it (hence bounded), one can easily see that there exists a constant $C_d > 0$ such that (2.11) holds for any $\boldsymbol{\xi} \in \mathbb{R}_*^d$, $\frac{1}{4} \leq |\boldsymbol{\xi}| \leq 4$.

For $|\boldsymbol{\xi}| \in (0, \frac{1}{2})$, by Lemma 2.2 there exists $\tilde{\psi}_0 \in C^{\lfloor \frac{d}{2} \rfloor + 1}([0, 1) \times S^{d-1})$ such that $\psi(\boldsymbol{\xi}) = \tilde{\psi}_0(|\boldsymbol{\xi}|, \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|})$.

Since $\boldsymbol{\xi} \mapsto \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}$ is homogeneous of degree zero, each of its components satisfies Mihlin's condition (2.10) (see e.g. [36, Section 5.2.2]). For $\boldsymbol{\xi} \mapsto |\boldsymbol{\xi}|$ we have $\partial_j |\boldsymbol{\xi}| = \frac{\xi_j}{|\boldsymbol{\xi}|}$, thus by the previous observation for $\alpha \in \mathbb{N}_0^d$, $|\alpha| \geq 1$, we have

$$\partial^\alpha |\boldsymbol{\xi}| \leq \frac{C}{|\boldsymbol{\xi}|^{|\alpha|-1}} \leq \frac{C}{|\boldsymbol{\xi}|^{|\alpha|}}, \quad |\boldsymbol{\xi}| \in \left(0, \frac{1}{2}\right),$$

where in the second inequality we have used that $\frac{1}{|\boldsymbol{\xi}|} > 1$ on the observed set. Therefore, each component of the function $\mathcal{J}_0(\boldsymbol{\xi}) = (|\boldsymbol{\xi}|, \frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|})$ satisfies Mihlin's condition. Then by the Faá di Bruno formula (2.9) for $|\boldsymbol{\xi}| \in (0, \frac{1}{2})$ we get

$$|\partial^\alpha \psi(\boldsymbol{\xi})| \leq \frac{\tilde{C}_d}{|\boldsymbol{\xi}|^{|\alpha|}} |\alpha|! \sum_{\substack{\boldsymbol{\beta} \in \mathbb{N}_0^d, \\ 1 \leq |\boldsymbol{\beta}| \leq |\alpha|}} \frac{|(\partial^{\boldsymbol{\beta}} \tilde{\psi}_0)(\mathcal{J}_0(\boldsymbol{\xi}))|}{\boldsymbol{\beta}!} \leq \frac{C_d \|\psi\|_{C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))}}{|\boldsymbol{\xi}|^{|\alpha|}},$$

where in the last inequality we have used Lemma 2.5, while \tilde{C}_d and C_d are constants depending only on the dimension of space d .

The remaining case $|\boldsymbol{\xi}| \in (2, \infty)$ follows in the same manner since $\psi(\boldsymbol{\xi}) = \tilde{\psi}_\infty(\mathcal{J}_\infty(\boldsymbol{\xi}))$ in this case, and all components of \mathcal{J}_∞ satisfy the Mihlin condition on this set (it is important to take into account that $|\boldsymbol{\xi}| > 2$). \square

By the previous theorem we have that, for any $d \geq 1$ and $p \in (1, \infty)$, the linear mapping

$$C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d)) \ni \psi \mapsto \mathcal{A}_\psi \in \mathcal{L}(L^p(\mathbb{R}^d))$$

is continuous.

2.4. Commutation lemma. For $\varphi \in L^\infty(\mathbb{R}^d)$, let us denote by $B_\varphi u = \varphi u$ the operator of multiplication by φ . This operator is clearly bounded on $L^p(\mathbb{R}^d; \mathbb{C}^r)$, for any $p \in [1, \infty]$, with the norm being equal to the L^∞ norm of φ .

Thus, by Theorem 2.9 (see also Lemma 2.12 below), for $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$ and $\omega_n \rightarrow 0^+$ the sequence of commutators

$$[B_\varphi, \mathcal{A}_{\psi_n}] := B_\varphi \mathcal{A}_{\psi_n} - \mathcal{A}_{\psi_n} B_\varphi,$$

where $\psi_n(\boldsymbol{\xi}) := \psi(\omega_n \boldsymbol{\xi})$, is bounded in $\mathcal{L}(L^p(\mathbb{R}^d))$, for any $p \in (1, \infty)$. The above sequence of operators (under an additional assumption on φ) has a special structure, which can be seen in

[7, Lemma 3] for the L^2 case. Here we generalise that result by the interpolation argument to the L^p , $p \in (1, \infty)$, setting.

Lemma 2.10. *Let $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$, $\varphi \in C_0(\mathbb{R}^d)$, $\omega_n \rightarrow 0^+$, and denote $\psi_n(\boldsymbol{\xi}) := \psi(\omega_n \boldsymbol{\xi})$. Then the commutator of multiplication and the Fourier multiplier can be expressed as a sum*

$$C_n := [B_\varphi, \mathcal{A}_{\psi_n}] = \tilde{C}_n + K,$$

where for any $p \in (1, \infty)$ we have that K is a compact operator on $L^p(\mathbb{R}^d)$, while $\tilde{C}_n \rightarrow 0$ in the operator norm on $\mathcal{L}(L^p(\mathbb{R}^d))$.

Proof. Since

$$\mathcal{A}_{\psi_n} = \mathcal{A}_{\psi_n - \psi_0 \circ \pi} + \mathcal{A}_{\psi_0 \circ \pi}$$

(recall that ψ_0 is given by (2.8)), we have that $C_n = \tilde{C}_n + K$, where $\tilde{C}_n := [B_\varphi, \mathcal{A}_{\psi_n - \psi_0 \circ \pi}]$ and $K := [B_\varphi, \mathcal{A}_{\psi_0 \circ \pi}]$. By the standard First commutation lemma [61, Lemma 1.7] K is a compact operator on $L^2(\mathbb{R}^d)$, while applying [62, Lemma 32.4] $\tilde{C}_n \rightarrow 0$ in the operator norm on $\mathcal{L}(L^2(\mathbb{R}^d))$.

As $\psi_0 \in C^{\lfloor \frac{d}{2} \rfloor + 1}(S^{d-1})$, we have $\psi_0 \circ \pi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ (see Corollary 2.6(i)). Thus, $\psi_0 \circ \pi$ is an L^p Fourier multiplier for any $p \in (1, \infty)$ (this is, of course, a well known fact; see e.g. [36, Section 5.2.2]), which implies that for any $p \in (1, \infty)$ the operator K is bounded on $L^p(\mathbb{R}^d)$ (the bound is not uniform in p , which does not cause any problems). On the other hand, since multipliers are invariant under dilations (see [36, Proposition 2.5.14] or Lemma 2.12 below), by Theorem 2.9 the sequence of operators (\tilde{C}_n) is uniformly (with respect to n) bounded on $L^p(\mathbb{R}^d)$, $p \in (1, \infty)$.

Let $p \in (1, \infty)$ be arbitrary, but fixed. Then there exist $r \in (1, \infty)$ and $\theta \in (0, 1)$ such that $1/p = \theta/2 + (1 - \theta)/r$. Since K is compact on $L^2(\mathbb{R}^d)$ and bounded on $L^r(\mathbb{R}^d)$, by the result due to Krasnosel'skij (see [8, Lemma 3], [12] and references therein) we get that K is compact on $L^p(\mathbb{R}^d)$.

Similarly, by using the Riesz-Thorin interpolation theorem (see e.g. [36, Theorem 1.3.4]) we obtain

$$\|\tilde{C}_n\|_{\mathcal{L}(L^p(\mathbb{R}^d))} \leq \|\tilde{C}_n\|_{\mathcal{L}(L^2(\mathbb{R}^d))}^\theta \|\tilde{C}_n\|_{\mathcal{L}(L^r(\mathbb{R}^d))}^{1-\theta},$$

implying $\tilde{C}_n \rightarrow 0$ in the operator norm on $L^p(\mathbb{R}^d)$. \square

Remark 2.11. For $\psi = \tilde{\psi} \circ \pi$, where $\tilde{\psi} \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ (see Corollary 2.6(i)), it is obvious that $\tilde{C}_n = 0$. Thus, the previous lemma can be seen as a generalisation of [8, Corollary 3] as well.

The following simple result we provide for completeness.

Lemma 2.12. *Let $\psi \in L^\infty(\mathbb{R}^d) \cap C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{R}_*^d)$ satisfy Mihlin's condition:*

$$(\forall \boldsymbol{\xi} \in \mathbb{R}_*^d)(\forall \boldsymbol{\alpha} \in \mathbb{N}_0^d) \quad |\boldsymbol{\alpha}| \leq \left\lfloor \frac{d}{2} \right\rfloor + 1 \implies |\partial^{\boldsymbol{\alpha}} \psi(\boldsymbol{\xi})| \leq \frac{C}{|\boldsymbol{\xi}^{|\boldsymbol{\alpha}}|}.$$

Then for any $a > 0$ the function $\psi_a := \psi(a \cdot)$ also satisfies the Mihlin condition with the same constant C .

Proof. For $|\boldsymbol{\alpha}| \leq \lfloor \frac{d}{2} \rfloor + 1$ and $\boldsymbol{\xi} \in \mathbb{R}_*^d$ we have

$$|\partial^{\boldsymbol{\alpha}} \psi_a(\boldsymbol{\xi})| = a^{|\boldsymbol{\alpha}|} |(\partial^{\boldsymbol{\alpha}} \psi)(a \boldsymbol{\xi})| \leq a^{|\boldsymbol{\alpha}|} \frac{C}{|a \boldsymbol{\xi}^{|\boldsymbol{\alpha}}|} = \frac{C}{|\boldsymbol{\xi}^{|\boldsymbol{\alpha}}|},$$

proving the claim. \square

3. KERNEL THEOREM

3.1. Anisotropic distributions on manifolds without boundary. In the next section we shall study certain Schwartz' distributions [60] of finite order in both variables \mathbf{x} (the physical variable) and $\boldsymbol{\xi}$ (the dual variable) on a manifold with boundary. Although such distributions are not in general Radon measures (distributions of order 0), we shall be able to prove that at least the order with respect to \mathbf{x} is 0. In order to do so, we need to work with distributions of *anisotropic* order, which have recently been introduced on manifolds without boundary in [8] as *anisotropic distributions*. Let us start by recalling the definition of these objects.

For simplicity, let us explain the construction for an open subset $\Omega \subseteq \mathbb{R}_x^d \times \mathbb{R}_y^r$, while the case where \mathbb{R}^d and \mathbb{R}^r are replaced by differentiable manifolds without boundary X and Y then easily follows using the local nature of distributions and the fact that every differentiable manifold is locally diffeomorphic to some Euclidean space.

For $l, m \in \mathbb{N}_0 \cup \{\infty\}$ we introduce the following space of functions:

$$C^{l,m}(\Omega) := \left\{ f : \Omega \rightarrow \mathbb{C} : (\forall \boldsymbol{\alpha} \in \mathbb{N}_0^d)(\forall \boldsymbol{\beta} \in \mathbb{N}_0^r) \ |\boldsymbol{\alpha}| \leq l \ \& \ |\boldsymbol{\beta}| \leq m \implies \partial_{\mathbf{x}}^{\boldsymbol{\alpha}} \partial_{\mathbf{y}}^{\boldsymbol{\beta}} f \in C(\Omega) \right\},$$

where the partial order on \mathbb{N}_0 is naturally extended by $k \leq \infty$, $k \in \mathbb{N}_0 \cup \{\infty\}$. Thus, $C^{0,0}(\Omega) = C(\Omega)$ and $C^{\infty,\infty}(\Omega) = C^\infty(\Omega)$, but in general we have only

$$C^{l+m}(\Omega) \subseteq C^{l,m}(\Omega) \subseteq C^{\min\{l,m\}}(\Omega),$$

where we extend the addition to $\mathbb{N}_0 \cup \{\infty\}$ by taking $k + \infty = \infty$, for any $k \in \mathbb{N}_0 \cup \{\infty\}$.

Take a sequence of nested compact sets K_n in Ω , such that $\Omega = \bigcup_{n \in \mathbb{N}} K_n$ and $K_n \subseteq \text{Int } K_{n+1}$ (by $\text{Int } A$ we denote the interior of set A), and for $l, m \in \mathbb{N}_0$ and $f \in C^{l,m}(\Omega)$ we define the seminorms

$$(3.1) \quad p_{K_n}^{l,m}(f) := \max_{|\boldsymbol{\alpha}| \leq l, |\boldsymbol{\beta}| \leq m} \|\partial^{\boldsymbol{\alpha}, \boldsymbol{\beta}} f\|_{L^\infty(K_n)}.$$

If $l = \infty$, instead of seminorms in (3.1), we take the following sequence of seminorms on $C^{\infty,m}(\Omega)$:

$$p_{K_n}^{n,m}(f) := \max_{|\boldsymbol{\alpha}| \leq n, |\boldsymbol{\beta}| \leq m} \|\partial^{\boldsymbol{\alpha}, \boldsymbol{\beta}} f\|_{L^\infty(K_n)},$$

and similarly for $m = \infty$ (of course, the choice $l = m = \infty$ reduces to the standard isotropic case of $C^\infty(\Omega)$). For $l, m \in \mathbb{N}_0 \cup \{\infty\}$ these seminorms turn $C^{l,m}(\Omega)$ into a separable Fréchet space with the topology of uniform convergence on compact sets of functions and their derivatives up to order l in \mathbf{x} and m in \mathbf{y} , while $C_c^\infty(\Omega)$ is dense in it (cf. [8, Theorem 1]). For a compact set $K \subseteq \Omega$ and finite l and m , its subspace

$$C_K^{l,m}(\Omega) := \left\{ f \in C^{l,m}(\Omega) : \text{supp } f \subseteq K \right\}$$

is a Banach space, and the inherited topology from $C^{l,m}(\Omega)$ is a norm topology determined by

$$\|f\|_{l,m,K} := p_K^{l,m}(f).$$

If $l = \infty$ or $m = \infty$, then we shall not get a Banach space, but a Fréchet space. Finally, the set of all $C^{l,m}(\Omega)$ functions with compact support

$$C_c^{l,m}(\Omega) := \bigcup_{n \in \mathbb{N}} C_{K_n}^{l,m}(\Omega)$$

we equip with the topology of strict inductive limit, obtaining a complete locally convex topological vector space.

Definition 3.1. Any continuous linear functional on $C_c^{l,m}(\Omega)$ we call a *distribution of anisotropic order*, and such functionals form a vector space denoted by $\mathcal{D}'_{l,m}(\Omega) := (C_c^{l,m}(\Omega))'$.

A linear functional T on $C_c^{l,m}(\Omega)$ is continuous (at zero) if and only if its restriction to any space $C_K^{l,m}(\Omega)$, where $K \subseteq \Omega$ is a compact, is continuous (at zero) [8], meaning that

$$(\forall K \Subset \Omega)(\exists C > 0)(\forall \varphi \in C_c^{l,m}(\Omega)) \quad \text{supp } \varphi \subseteq K \implies |\langle T, \varphi \rangle| \leq Cp_K^{l,m}(\varphi) .$$

If either l or m is infinite, we have to modify the above in the obvious way.

Since inclusions $C_c^\infty(\Omega) \hookrightarrow C_c^{l,m}(\Omega)$ are continuous and dense, any distribution of anisotropic order is a distribution. In fact, by the equivalent definition of continuity above, we can characterise anisotropic distributions as distributions of order (l, m) , i.e.

$$T \in \mathcal{D}'_{l,m}(\Omega) \iff \begin{cases} T \in \mathcal{D}'(\Omega), \text{ and} \\ (\forall K \Subset \Omega)(\exists C > 0)(\forall \varphi \in C_K^\infty(\Omega)) \quad |\langle T, \varphi \rangle| \leq Cp_K^{l,m}(\varphi) , \end{cases}$$

where, again, if either l or m is infinite, we have to modify the above in the obvious way.

Let us now consider the case when Ω is an open subset of a differentiable manifold without boundary. To be precise, under the notion *differential manifold without boundary of dimension d* we mean a locally Euclidean (of the fixed dimension d , i.e. locally diffeomorphic to \mathbb{R}^d) second countable Hausdorff topological space on which an equivalence class of C^∞ smooth atlases is given. In particular, every differentiable manifold without boundary X is paracompact, hemicompact (i.e. admits a countable compact exhaustion), separable, metrisable, and for any open cover of X there exists a smooth partition of unity subordinate to this cover (see e.g. [21, 16.1–4] or [47, Chapter 1]).

Definition 3.1 applies also when Ω is an open subset of $X \times Y$, where X and Y are differentiable manifolds without boundary of dimensions d and r , respectively. Indeed, the construction is completely standard by means of reducing the problem (locally) to charts (a detailed construction can be found in [8, Subsection 2.2]).

Since the main advantage of using anisotropic distributions is to give a more precise description of the order of distributions, one needs a more precise version of the Schwartz kernel theorem (the classical kernel theorem for manifolds without boundary can be found in [21, 23.9.2]). In [8, Theorem 5] the following theorem has been proven.

Theorem 3.2. *Let X and Y be differential manifolds, of dimension d and r , and $l, m \in \mathbb{N}_0 \cup \{\infty\}$. Then the following statements hold:*

- i) *If $K \in \mathcal{D}'_{l,m}(X \times Y)$, then for each $\varphi \in C_c^l(X)$ the linear form K_φ , defined by $\psi \mapsto \langle K, \varphi \otimes \psi \rangle$, is a distribution of order not more than m on Y . Furthermore, the mapping $\varphi \mapsto K_\varphi$, taking $C_c^l(X)$ with its strict inductive limit topology to $\mathcal{D}'_m(Y)$ with weak $*$ topology, is linear and continuous.*
- ii) *Let $A : C_c^l(X) \rightarrow \mathcal{D}'_m(Y)$ be a continuous linear operator, in the pair of topologies as in (i) above. Then there exists a unique distribution of anisotropic order $K \in \mathcal{D}'_{l,r(m+2)}(X \times Y)$ such that for any $\varphi \in C_c^l(X)$ and $\psi \in C_c^{r(m+2)}(Y)$ one has*

$$\langle K, \varphi \otimes \psi \rangle = \langle K_\varphi, \psi \rangle = \langle A\varphi, \psi \rangle .$$

A nice property of the second statement in the previous theorem is the fact that we can keep the order with respect to one space unchanged. In particular, if we have $l = 0$, then the resulting kernel distribution is still defined on merely continuous functions in X .

3.2. Anisotropic distributions on manifolds with boundary. For the construction of one-scale H-distributions (which is the main result of the following section) we need to study distributions on $K_{0,\infty}(\mathbb{R}^d)$. Since $K_{0,\infty}(\mathbb{R}^d)$ is not a manifold without boundary, but can be understood as a (compact) manifold with boundary, we need to generalise the notion of anisotropic distributions and the corresponding kernel theorem of the previous subsection. In order to avoid any confusions, let us stress that the definition of *differential manifolds with boundary* used here differs from the notion of differential manifolds without boundary only in the fact that we allow that the former is diffeomorphic either to \mathbb{R}^d or to the closed half-space $\text{Cl}\mathbb{R}_+^d = \{\mathbf{x} = (x_1, x_2, \dots, x_d) \in \mathbb{R}^d : x_d \geq 0\}$ (see e.g. [47, Chapter 1]).

For simplicity of the presentation, in this subsection we shall consider only the case $X = \Omega$, $\Omega \subseteq \mathbb{R}^d$ open, and $Y = K_{0,\infty}(\mathbb{R}^d)$, while one can generalise all the conclusions to the case where X and Y are differentiable manifolds without boundary and with boundary, respectively (some remarks in this direction are addressed at the end of this subsection).

Since studying distributions on compact sets is not completely standard, let us start by fixing our notation.

The space of distributions on $K_{0,\infty}(\mathbb{R}^d)$ of order $l \in \mathbb{N} \cup \{\infty\}$ we define by

$$\mathcal{D}'_l(K_{0,\infty}(\mathbb{R}^d)) = (C^l(K_{0,\infty}(\mathbb{R}^d)))',$$

where the case $l = \infty$ we shall also denote by $\mathcal{D}'(K_{0,\infty}(\mathbb{R}^d))$. Of course, for any $l \leq m$ we have the continuous inclusion $\mathcal{D}'_l(K_{0,\infty}(\mathbb{R}^d)) \subseteq \mathcal{D}'_m(K_{0,\infty}(\mathbb{R}^d))$.

Although this definition is quite natural and simple, one needs to be careful how to define derivatives of these objects since the integration by parts leaves some nontrivial boundary terms (as test functions do not vanish on the boundary). Such difficulties will not occur in the present manuscript, so we shall not elaborate on the issue in more detail.

For $\Omega \subseteq \mathbb{R}^d$ open, the space of anisotropic distributions on $\Omega \times K_{0,\infty}(\mathbb{R}^d)$ of order $(l, m) \in (\mathbb{N} \cup \{\infty\})^2$ is defined by

$$(3.2) \quad \mathcal{D}'_{l,m}(\Omega \times K_{0,\infty}(\mathbb{R}^d)) = (C_c^{l,m}(\Omega \times K_{0,\infty}(\mathbb{R}^d)))'.$$

Since $K_{0,\infty}(\mathbb{R}^d)$ is a compact set, the compact support of test functions matters only with respect to the first variable $\mathbf{x} \in \Omega$.

Let us note that it is sufficient to introduce distributions on $\Omega \times S_{[0,r_1]}^d$ since by applying the pushforward $(\mathcal{J}^{-1})_*$ we have a one-to-one correspondence with distributions on $\Omega \times K_{0,\infty}(\mathbb{R}^d)$. More precisely, the mapping $(\mathcal{J}^{-1})_*$ given by

$$\langle (\mathcal{J}^{-1})_* \nu, \Phi \rangle = \langle \nu, \Phi(\cdot, \mathcal{J}^{-1}(\cdot)) \rangle, \quad \nu \in \mathcal{D}'_{l,m}(\Omega \times S_{[0,r_1]}^d),$$

defines an isomorphism between spaces $\mathcal{D}'_{l,m}(\Omega \times S_{[0,r_1]}^d)$ and $\mathcal{D}'_{l,m}(\Omega \times K_{0,\infty}(\mathbb{R}^d))$. Here the space $\mathcal{D}'_{l,m}(\Omega \times S_{[0,r_1]}^d)$ is defined in the same manner as in (3.2), i.e. $\mathcal{D}'_{l,m}(\Omega \times S_{[0,r_1]}^d) = (C_c^{l,m}(\Omega \times S_{[0,r_1]}^d))'$.

It can easily be seen that $S_{[0,r_1]}^d$ is an embedded submanifold with boundary in the unit sphere around the origin in \mathbb{R}^{d+1} , denoted by S^d . Indeed, it is even a *regular domain* in S^d (cf. [47, Chapter 5]) with a *defining function* $S^d \ni (\zeta_0, \boldsymbol{\eta}) \mapsto \zeta_0$ (see (2.2)). Thus, there exists a simultaneous linear extension

$$E : C^m(S_{[0,r_1]}^d) \rightarrow C^m(S^d)$$

which is continuous and such that $E(\psi)|_{\mathbb{S}_{[0,r_1]}^d} = \psi$. This can easily be proved by using the Seeley extension theorem for the half line and the local character of manifolds with boundary, or by the above defining function. A nice exposition on extension theorems can be found in [15, Chapter 2].

The restriction operator $R : C^m(\mathbb{S}^d) \rightarrow C^m(\mathbb{S}_{[0,r_1]}^d)$ defined by $R\psi = \psi|_{\mathbb{S}_{[0,r_1]}^d}$ is linear and continuous. Moreover, since for $\psi \in C^m(\mathbb{S}_{[0,r_1]}^d)$ we have $\psi = R(E\psi)$, the restriction operator is surjective.

We shall make a small abuse of notation and use the same symbol E for the extension operator from $\Omega \times \mathbb{S}_{[0,r_1]}^d$ to $\Omega \times \mathbb{S}^d$, which is defined on tensor products by $E(\varphi \otimes \psi) = \varphi \otimes E\psi$.

Let us consider a continuous linear operator $A : C_c^l(\Omega) \rightarrow \mathcal{D}'_m(\mathbb{S}_{[0,r_1]}^d)$, where the inductive limit topology is assumed on $C_c^l(\Omega)$ and the weak $*$ topology on $\mathcal{D}'_m(\mathbb{S}_{[0,r_1]}^d)$. We want to show a statement analogous to Theorem 3.2(ii). The strategy is to reduce the problem to the setting of Theorem 3.2.

By

$$\langle \tilde{A}\varphi, \tilde{\psi} \rangle = \langle A\varphi, R\tilde{\psi} \rangle, \quad \varphi \in C_c^l(\Omega), \tilde{\psi} \in C^m(\mathbb{S}^d),$$

a continuous linear operator $\tilde{A} : C_c^l(\Omega) \rightarrow \mathcal{D}'_m(\mathbb{S}^d)$ is defined. Applying Theorem 3.2(ii) we get the distributional kernel $\tilde{K} \in \mathcal{D}'_{l,d(m+2)}(\Omega \times \mathbb{S}^d)$ such that for any $\varphi \in C_c^l(\Omega)$ and $\tilde{\psi} \in C^{d(m+2)}(\mathbb{S}^d)$ it holds

$$\langle \tilde{K}, \varphi \otimes \tilde{\psi} \rangle = \langle \tilde{A}\varphi, \tilde{\psi} \rangle.$$

Finally, we define $K \in \mathcal{D}'_{l,d(m+2)}(\Omega \times \mathbb{S}_{[0,r_1]}^d)$ by

$$\langle K, \Phi \rangle = \langle \tilde{K}, E\Phi \rangle, \quad \Phi \in C^{l,d(m+2)}(\Omega \times \mathbb{S}_{[0,r_1]}^d),$$

and it remains to be seen that K is the kernel of operator A .

Using the above, for any $\varphi \in C_c^l(X)$ and $\psi \in C^{d(m+2)}(\mathbb{S}_{[0,r_1]}^d)$ we have

$$\langle K, \varphi \otimes \psi \rangle = \langle \tilde{K}, \varphi \otimes E\psi \rangle = \langle \tilde{A}\varphi, E\psi \rangle = \langle A\varphi, R(E\psi) \rangle = \langle A\varphi, \psi \rangle.$$

Therefore, we have proved the following corollary of Theorem 3.2.

Corollary 3.3. *Let $\Omega \subseteq \mathbb{R}^d$ be open and $l, m \in \mathbb{N}_0 \cup \{\infty\}$. Furthermore, let $A : C_c^l(\Omega) \rightarrow \mathcal{D}'_m(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ be a continuous linear operator, taking $C_c^l(\Omega)$ with its inductive limit topology and $\mathcal{D}'_m(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ with weak $*$ topology.*

Then there exists a unique distribution of anisotropic order $K \in \mathcal{D}'_{l,d(m+2)}(\Omega \times \mathbb{K}_{0,\infty}(\mathbb{R}^d))$ such that for any $\varphi \in C_c^l(X)$ and $\psi \in C^{d(m+2)}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ one has

$$\langle K, \varphi \otimes \psi \rangle = \langle A\varphi, \psi \rangle.$$

Remark 3.4. i) The transition from $\mathbb{K}_{0,\infty}(\mathbb{R}^d)$ to $\mathbb{S}_{[0,r_1]}^d$ in the analysis above is not essential. Indeed, if we had an arbitrary differential manifold Y instead of $\mathbb{K}_{0,\infty}(\mathbb{R}^d)$, the existence of a differential manifold without boundary \tilde{Y} in which Y is embedded would be ensured by the standard theory of smooth manifolds (see e.g. Theorem 6.15 and Example 9.32 in [47]). Furthermore, a simultaneous linear extension from Y to \tilde{Y} exists even in this general case (see e.g. [15, Section 2.2]), which can also be proven constructively by using the local character of manifolds with boundary.

ii) In [52] one can find a more general theory of distributions on manifolds with corners. In order to have well defined integrals in such generality (i.e. to be able to *identify* functions with distributions), one has to consider densities either at the level of distributions or at the level of test functions. Since $S_{[0,r_1]}^d$ is a regular domain in S^d , it is orientable, hence we have a canonical way how to integrate differential d -forms. Therefore, in our situation explicit reference to densities can be avoided.

Moreover, in [52, Chapter 3] three different definitions of distributions on manifolds with corners are presented. Let us briefly mention all of them. For a smooth compact manifold with corners X let us denote by ΩX a C^∞ line bundle over X consisting of densities (1-densities). The spaces

$$(C_c^\infty(\text{Int } X; \Omega X))', \quad (C^\infty(X; \Omega X))' \quad \text{and} \quad (C_0^\infty(X; \Omega X))'$$

are called *distributions in the interior*, *supported distributions* and *extendible distributions*, respectively. Thus, our choice corresponds to supported distributions.

4. ONE-SCALE H-DISTRIBUTIONS

4.1. Existence and first properties. Now we have prepared all the prerequisites required for the construction of one-scale H-distributions.

Theorem 4.1 (existence of one-scale H-distributions). *Let $\Omega \subseteq \mathbb{R}^d$ be open. If $u_n \rightharpoonup 0$ in $L_{\text{loc}}^p(\Omega)$ and (v_n) is bounded in $L_{\text{loc}}^q(\Omega)$ (for some $p \in (1, \infty)$ and $q \geq p'$, where $1/p + 1/p' = 1$), and if $\omega_n \rightarrow 0^+$, then there exist subsequences $(u_{n'})$, $(v_{n'})$, and a complex valued (supported) distribution $\nu_{K_{0,\infty}}^{(\omega_{n'})} \in \mathcal{D}'_{0,\kappa}(\Omega \times K_{0,\infty}(\mathbb{R}^d))$, where $\kappa := d(\lfloor \frac{d}{2} \rfloor + 3)$, such that for any $\varphi_1, \varphi_2 \in C_c(\Omega)$ and $\psi \in C^\kappa(K_{0,\infty}(\mathbb{R}^d))$, one has:*

$$(4.1) \quad \lim_{n' \rightarrow \infty} \int_{\mathbb{R}^d} \mathcal{A}_{\psi_{n'}}(\varphi_1 u_{n'}) (\mathbf{x}) \overline{(\varphi_2 v_{n'}) (\mathbf{x})} d\mathbf{x} = \lim_{n' \rightarrow \infty} \int_{\mathbb{R}^d} (\varphi_1 u_{n'}) (\mathbf{x}) \overline{\mathcal{A}_{\bar{\psi}_{n'}}(\varphi_2 v_{n'}) (\mathbf{x})} d\mathbf{x} \\ = \left\langle \nu_{K_{0,\infty}}^{(\omega_{n'})}, \varphi_1 \bar{\varphi}_2 \otimes \psi \right\rangle,$$

where $\psi_n = \psi(\omega_n \cdot)$. The distribution $\nu_{K_{0,\infty}}^{(\omega_{n'})}$ we call the one-scale H-distribution (with the characteristic length $(\omega_{n'})$) associated to (sub)sequences $(u_{n'})$ and $(v_{n'})$.

Moreover, for $p = 2$ the one-scale H-distribution above is the one-scale H-measures with characteristic length $(\omega_{n'})$ associated to (sub)sequences $(u_{n'})$ and $(v_{n'})$.

Proof. Let us first observe that for $p = q = 2$, after applying the Plancherel theorem, (4.1) reveals the definition of one-scale H-measures ([62, Lemma 32.6], [7, Theorem 6]), and since the space $C^\kappa(K_{0,\infty}(\mathbb{R}^d))$ is dense in $C(K_{0,\infty}(\mathbb{R}^d))$, we get the claim.

Returning to the general p , we should note that for $q \geq p'$, $(\varphi_2 v_n)$ is bounded in $L^{p'}(\Omega)$ as well, so we can work as if $q = p'$.

The first equality in (4.1) stems from the fact that $\mathcal{A}_{\bar{\psi}_{n'}}$ is the adjoint of $\mathcal{A}_{\psi_{n'}}$.

Let us choose arbitrary test functions $\varphi_1, \varphi_2 \in C_c(\Omega)$ and $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$. Then there exists a compact set $K \subseteq \Omega$ such that the supports of both φ_1 and φ_2 are contained in it. By Theorem 2.9 (bearing in mind the invariance of multipliers under dilations; see Lemma 2.12), the sequence $(\mathcal{A}_{\bar{\psi}_n}(\varphi_1 u_n))$ is bounded in $L^p(\mathbb{R}^d)$. Thus, by the Hölder inequality the following

sequence of integrals is bounded (in \mathbb{C}):

$$\left| \int_{\mathbb{R}^d} \mathcal{A}_{\psi_n}(\varphi_1 u_n)(\mathbf{x}) \overline{(\varphi_2 v_n)(\mathbf{x})} dx \right| \leq C \|\varphi_1\|_{L^\infty(K)} \|\varphi_2\|_{L^\infty(K)} \|\psi\|_{C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))},$$

where $C = C_{d,p} C_d (\sup_n \|u_n\|_{L^p(K)}) (\sup_n \|v_n\|_{L^{p'}(K)})$, while $C_{d,p}$ and C_d are the constants given in Theorem 2.9. Hence, we can pass to a subsequence converging to a limit satisfying the same bound. Moreover, since $C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ and

$$\{\varphi \in C_c(\Omega) : \text{supp } \varphi \subseteq K\}$$

are both separable Banach spaces, while $C_c(\Omega)$ can be expressed as a strict inductive limit of the latter spaces, this passage can be done in such a way that the obtained subsequence is good for any choice of test functions (see the proof of [7, Theorem 6]). The corresponding subsequences we denote by $(u_{n'})$ and $(v_{n'})$.

Therefore, by

$$(4.2) \quad L(\varphi_1, \varphi_2, \psi) = \lim_{n'} \langle \overline{\varphi_2 v_{n'}}, \mathcal{A}_{\psi_{n'}}(\varphi_1 u_{n'}) \rangle_{L^p}$$

a trilinear form on $C_c(\Omega) \times C_c(\Omega) \times C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ is defined. Furthermore, $L(\varphi_1, \varphi_2, \psi)$ depends only on the product $\varphi_1 \bar{\varphi}_2$ (and not on both φ_1 and φ_2 independently). Indeed, let us denote by $\zeta_i \in C_c(\Omega)$ an arbitrary function which is equal to 1 on the support of φ_i , $i = 1, 2$. Then we have

$$\begin{aligned} \lim_{n'} \langle \overline{\varphi_2 v_{n'}}, \mathcal{A}_{\psi_{n'}}(\varphi_1 u_{n'}) \rangle_{L^p} &= \lim_{n'} \langle \overline{\varphi_2 v_{n'}}, \varphi_1 \mathcal{A}_{\psi_{n'}}(\zeta_1 u_{n'}) \rangle_{L^p} \\ &= \lim_{n'} \langle \overline{\bar{\varphi}_1 \varphi_2 v_{n'}}, \mathcal{A}_{\psi_{n'}}(\zeta_1 u_{n'}) \rangle_{L^p} \\ &= \lim_{n'} \langle \overline{\zeta_1 \zeta_2 v_{n'}}, \varphi_1 \bar{\varphi}_2 \mathcal{A}_{\psi_{n'}}(\zeta_1 u_{n'}) \rangle_{L^p} \\ &= \lim_{n'} \langle \overline{\zeta_1 \zeta_2 v_{n'}}, \mathcal{A}_{\psi_{n'}}(\varphi_1 \bar{\varphi}_2 u_{n'}) \rangle_{L^p}, \end{aligned}$$

where in the first and the last equality we have used Lemma 2.10 and the assumption that $u_n \rightarrow 0$ in $L^p_{\text{loc}}(\Omega)$. Since $\zeta_1 \zeta_2$ depends only on $\varphi_1 \bar{\varphi}_2$ (we only need $\zeta_1 \zeta_2 = 1$ on the support of $\varphi_1 \bar{\varphi}_2$), we have the conclusion.

For $\varphi \in C_c(\Omega)$ and $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ let us define $B(\varphi, \psi) := L(\varphi, \zeta, \psi)$, where $\zeta \in C_c(\Omega)$ is equal to 1 on the support of φ . By the computations above it is easy to see that B does not depend on the choice of ζ . Thus, B is a well-defined continuous bilinear form on $C_c(\Omega) \times C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d))$ which satisfies

$$(4.3) \quad B(\varphi_1 \bar{\varphi}_2, \psi) = L(\varphi_1, \varphi_2, \psi), \quad \varphi_1, \varphi_2 \in C_c(\Omega), \psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0,\infty}(\mathbb{R}^d)).$$

Now we can apply Corollary 3.3 on bilinear form B , which gives us the unique $\nu_{\mathbb{K}_{0,\infty}}^{(\omega_{n'})} \in \mathcal{D}'_{0,\kappa}(\Omega \times \mathbb{K}_{0,\infty}(\mathbb{R}^d))$. By (4.2) and (4.3), this distribution satisfies the required equality (4.1). \square

When it will cause no ambiguities, we shall omit explicit writing of the characteristic length, e.g. we shall use only $\nu_{\mathbb{K}_{0,\infty}}$ instead of $\nu_{\mathbb{K}_{0,\infty}}^{(\omega_{n'})}$, for simplicity.

Since the role of spaces in Corollary 3.3 can be interchanged, it is straightforward that one-scale H-distributions are contained in $\mathcal{D}'_{2d, \lfloor \frac{d}{2} \rfloor + 1}(\Omega \times \mathbb{K}_{0,\infty}(\mathbb{R}^d))$ as well. However, even the intersection $\mathcal{D}'_{0,\kappa}(\Omega \times \mathbb{K}_{0,\infty}(\mathbb{R}^d)) \cap \mathcal{D}'_{2d, \lfloor \frac{d}{2} \rfloor + 1}(\Omega \times \mathbb{K}_{0,\infty}(\mathbb{R}^d))$ does not provide an optimal

description of one-scale H-distributions as in the case $p = 2$ the resulting object is always a Radon measure (one-scale H-measure; cf. [63, 7]).

Remark 4.2. In fact, in the proof of the previous theorem we need only that at least one of sequences (u_n) , (v_n) converges weakly to zero (in the corresponding space). This was needed for application of Lemma 2.10. Thus, the statement of Theorem 4.1 still holds if (u_n) is merely bounded in $L^p_{loc}(\Omega)$ and $v_n \rightharpoonup 0$ in $L^{p'}_{loc}(\Omega)$.

Furthermore, for $\psi \in \mathcal{S}(\mathbb{R}^d)$ we can further weaken the assumptions and assume that (u_n) and (v_n) are only bounded (in the corresponding spaces), while (4.1) still holds. Indeed, for $\psi \in \mathcal{S}(\mathbb{R}^d)$, in the notation of Lemma 2.10, we have that operator $K = 0$ (since ψ is continuous at the origin, so there is no need for subtracting $\psi_0 \circ \pi$), which implies that the whole commutator $[B_\varphi, \mathcal{A}_{\psi_n}]$ converges to zero in the operator norm.

Since one-scale H-distributions are defined at the level of subsequences, for a given pair of sequences the corresponding one-scale H-distribution is not necessarily unique. Thus, we shall say that (u_n) and (v_n) form an (ω_n) -*pure pair of sequences* if the associated one-scale H-distribution with characteristic length (ω_n) is unique for any choice of subsequences. The order of sequences in the definition of one-scale H-distributions is important. However, the following straightforward relation holds (for the same result in the case of H-distributions, v. [8, Section 4]).

Lemma 4.3. *Let $\omega_n \rightarrow 0^+$ and let (u_n) and (v_n) form an (ω_n) -pure pair of sequences. Denote by $\nu_{K_{0,\infty}}$ the corresponding one-scale H-distribution.*

Then the pair (v_n) and (u_n) is also (ω_n) -pure, and the one-scale H-distribution corresponding to (v_n) and (u_n) is $\bar{\nu}_{K_{0,\infty}}$, where $\langle \bar{\nu}_{K_{0,\infty}}, \Psi \rangle = \langle \nu_{K_{0,\infty}}, \bar{\Psi} \rangle$.

The following property is an immediate consequence of the local nature of the definition of one-scale H-distributions.

Corollary 4.4. *Let (u_n) and (v_n) be sequences from Theorem 4.1. If there exist closed sets F_1 and F_2 in Ω such that all u_n keep their support in F_1 and v_n in F_2 , then the support of any one-scale H-distribution with any characteristic length corresponding to (sub)sequences of (u_n) and (v_n) is included in $(F_1 \cap F_2) \times K_{0,\infty}(\mathbb{R}^d)$.*

We have already seen in Theorem 4.1 that one-scale H-distributions are an extension of one-scale H-measures to the $L^p - L^q$ setting. Now let us show that in the $L^p - L^q$ framework the one-scale H-distributions are also an extension of H-distributions [13].

Corollary 4.5. *Let $\omega_n \rightarrow 0^+$ and let (u_n) and (v_n) form an (ω_n) -pure pair of sequences. Denote by $\nu_{K_{0,\infty}}^{(\omega_n)}$ the corresponding one-scale H-distribution.*

Then (u_n) and (v_n) form a pure pair of sequences, and the corresponding H-distribution is given by $\nu_H = \pi_ \nu_{K_{0,\infty}}^{(\omega_n)}$, i.e.*

$$(4.4) \quad \langle \nu_H, \Psi \rangle = \left\langle \nu_{K_{0,\infty}}^{(\omega_n)}, \Psi(\cdot, \pi(\cdot)) \right\rangle, \quad \Psi \in C^{0,\kappa}(\Omega \times S^{d-1}),$$

where $\pi(\xi) = \xi/|\xi|$.

Proof. The claim follows by Corollary 2.6(i) and the fact that for $\psi = \tilde{\psi} \circ \pi$, $\tilde{\psi} \in C^\kappa(S^{d-1})$, (4.1) reveals the definition of H-distributions (see [8, Theorem 7], [13, Theorem 2.1]). \square

Many other properties of H-distributions are also shared with their generalisation, the one-scale H-distributions. Let us emphasise here only the one related to compactness of weakly converging sequences. More precisely, we have the following result (cf. [8, Lemma 5]).

Lemma 4.6. *Let $u_n \rightharpoonup 0$ in $L^p_{\text{loc}}(\Omega)$, for some $p \in (1, \infty)$. Then the following statements are equivalent:*

- (a) $u_n \rightarrow 0$ (strongly) in $L^p_{\text{loc}}(\Omega)$.
- (b) For every bounded sequence (v_n) in $L^{p'}_{\text{loc}}(\Omega)$ and every $\omega_n \rightarrow 0^+$, (u_n) and (v_n) form an (ω_n) -pure pair and the corresponding one-scale H-distribution is zero.
- (c) For $v_n = |u_n|^{p-2}u_n$ and some $\omega_n \rightarrow 0^+$, (u_n) and (v_n) form an (ω_n) -pure pair and the corresponding one-scale H-distribution is zero.

Proof. It is trivial to see that (b) implies (c), while the implication from (c) to (a) follows by (4.4) and [8, Lemma 5 and Remark 7]. Finally, if $u_n \rightarrow 0$ in $L^p_{\text{loc}}(\Omega)$, then (4.1) is zero since $(\mathcal{A}_{\bar{\psi}_n}(\varphi_2 v_n))$ is bounded in $L^{p'}_{\text{loc}}(\mathbb{R}^d)$, thus implying (b). \square

Remark 4.7. The form of the sequence (v_n) in part (c) of the previous lemma is essential. More precisely, for a general bounded sequence (v_n) in $L^{p'}_{\text{loc}}(\Omega)$ and some $\omega_n \rightarrow 0^+$ for which (u_n) and (v_n) form an (ω_n) -pure pair and the corresponding one-scale H-distribution is zero we can only deduce that $u_n \bar{v}_n \xrightarrow{*} 0$ (vaguely) as (unbounded) Radon measures. This immediately follows by taking $\psi = 1$ in (4.1).

For vector valued sequences (\mathbf{u}_n) and (\mathbf{v}_n) we define the corresponding matrix one-scale H-distribution $\nu_{K_0, \infty}$ as a matrix which (i, j) -component, $\nu_{K_0, \infty}^{ij}$, is the one-scale H-distribution associated to the pair of sequences (u_n^i) and (v_n^j) .

4.2. Example I: Concentration. For $p \in (1, \infty)$, $\mathbf{z} \in \mathbb{R}^d$, and $\varepsilon > 0$, let us define a linear operator $\zeta_{p, \varepsilon}$ on $L^p(\mathbb{R}^d)$ by

$$\zeta_{p, \varepsilon} u(\mathbf{x}) = \varepsilon^{-\frac{d}{p}} u\left(\frac{\mathbf{x} - \mathbf{z}}{\varepsilon}\right).$$

Of course, $\zeta_{p, \varepsilon}$ depends on \mathbf{z} as well, but since it will be fixed, we choose to simplify the notation and omit the explicit writing of label \mathbf{z} . A simple change of variables shows that $\zeta_{p, \varepsilon}$ is a linear isometry on $L^p(\mathbb{R}^d)$, i.e. $\|\zeta_{p, \varepsilon} u\|_{L^p(\mathbb{R}^d)} = \|u\|_{L^p(\mathbb{R}^d)}$. Moreover, for any $\varepsilon_n \rightarrow 0^+$ and $u \in L^p(\mathbb{R}^d)$ the sequence $(\zeta_{p, \varepsilon_n} u)$ converges weakly to 0 in $L^p(\mathbb{R}^d)$ (cf. [8, Section 5]).

For arbitrary $\varepsilon_n \rightarrow 0^+$, $\omega_n \rightarrow 0^+$, $u \in L^p(\mathbb{R}^d)$, and $v \in L^{p'}(\mathbb{R}^d)$, where $1/p + 1/p' = 1$, we shall construct all one-scale H-distributions with the characteristic length (ω_n) associated to the pair of sequences $(\zeta_{p, \varepsilon_n} u)$ and $(\zeta_{p', \varepsilon_n} v)$.

For given u , a possible (canonical) choice for v can be $v = |u|^{p-2}u$.

First we list the following two simple lemmata that we use in the construction (cf. [8, lemmata 7 and 8]).

Lemma 4.8. *Let $p \in (1, \infty)$, $\mathbf{z} \in \mathbb{R}^d$, and $\varepsilon_n \rightarrow 0^+$. For any $u \in L^p(\mathbb{R}^d)$ and $\varphi \in C_c(\mathbb{R}^d)$ it holds*

$$\varphi \zeta_{p, \varepsilon_n} u - \varphi(\mathbf{z}) \zeta_{p, \varepsilon_n} u \longrightarrow 0 \text{ in } L^p(\mathbb{R}^d).$$

Lemma 4.9. *Let $p \in (1, \infty)$, $\mathbf{z} \in \mathbb{R}^d$, $\varepsilon > 0$, and let $\psi \in L^\infty(\mathbb{R}^d)$ be an L^p Fourier multiplier. Then*

$$\mathcal{A}_\psi \zeta_{p, \varepsilon} = \zeta_{p, \varepsilon} \mathcal{A}_{\psi(\frac{\cdot}{\varepsilon})}.$$

For arbitrary $\varphi_1, \varphi_2 \in C_c(\mathbb{R}^d)$ and $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$ we have

$$\begin{aligned} \lim_n \int_{\mathbb{R}^d} \mathcal{A}_{\psi(\omega_n \cdot)}(\varphi_1 \zeta_{p,\varepsilon_n} u)(\mathbf{x}) \overline{\varphi_2(\mathbf{x}) (\zeta_{p',\varepsilon_n} v)(\mathbf{x})} dx \\ &= \varphi_1(\mathbf{z}) \bar{\varphi}_2(\mathbf{z}) \lim_n \int_{\mathbb{R}^d} \mathcal{A}_{\psi(\omega_n \cdot)}(\zeta_{p,\varepsilon_n} u)(\mathbf{x}) \overline{(\zeta_{p',\varepsilon_n} v)(\mathbf{x})} dx \\ &= \varphi_1(\mathbf{z}) \bar{\varphi}_2(\mathbf{z}) \lim_n \int_{\mathbb{R}^d} (\zeta_{p,\varepsilon_n} \mathcal{A}_{\psi(\frac{\omega_n}{\varepsilon_n} \cdot)} u)(\mathbf{x}) \overline{(\zeta_{p',\varepsilon_n} v)(\mathbf{x})} dx \\ &= \varphi_1(\mathbf{z}) \bar{\varphi}_2(\mathbf{z}) \lim_n \int_{\mathbb{R}^d} \mathcal{A}_{\psi(\frac{\omega_n}{\varepsilon_n} \cdot)} u(\mathbf{y}) \overline{v(\mathbf{y})} dy, \end{aligned}$$

where we have used the preceding lemmata in the first two equalities, and the change of variables $\mathbf{y} = (\mathbf{x} - \mathbf{z})/\varepsilon_n$ in the last one.

Let us assume that the sequence of positive numbers $(\frac{\omega_n}{\varepsilon_n})$ converges in $\mathbb{R} \cup \{+\infty\}$ (if not, we just need to pass to a converging subsequence). Then by Lemma 4.10 (given below), Lemma 2.12 and Corollary 2.4, the sequence of integrals $\int_{\mathbb{R}^d} \mathcal{A}_{\psi(\frac{\omega_n}{\varepsilon_n} \cdot)} u(\mathbf{x}) \overline{v(\mathbf{x})} dx$ converges. More precisely

$$\lim_n \int_{\mathbb{R}^d} \mathcal{A}_{\psi(\frac{\omega_n}{\varepsilon_n} \cdot)} u(\mathbf{x}) \overline{v(\mathbf{x})} dx = \begin{cases} \langle \vartheta_0, \psi \rangle := \int_{\mathbb{R}^d} \mathcal{A}_{\psi_0 \circ \pi} u(\mathbf{x}) \overline{v(\mathbf{x})} dx, & \lim_n \frac{\omega_n}{\varepsilon_n} = 0 \\ \langle \vartheta_c, \psi \rangle := \int_{\mathbb{R}^d} \mathcal{A}_{\psi(c \cdot)} u(\mathbf{x}) \overline{v(\mathbf{x})} dx, & \lim_n \frac{\omega_n}{\varepsilon_n} = c \in (0, \infty) \\ \langle \vartheta_\infty, \psi \rangle := \int_{\mathbb{R}^d} \mathcal{A}_{\psi_\infty \circ \pi} u(\mathbf{x}) \overline{v(\mathbf{x})} dx, & \lim_n \frac{\omega_n}{\varepsilon_n} = \infty, \end{cases}$$

where ψ_0 and ψ_∞ are given by (2.8). Note that ϑ_γ , $\gamma \in [0, +\infty]$ defined above belong (at least) to the space $\mathcal{D}'_{\lfloor \frac{d}{2} \rfloor + 1}(K_{0,\infty}(\mathbb{R}^d))$ (distributions on $K_{0,\infty}(\mathbb{R}^d)$ of order not more than $\lfloor \frac{d}{2} \rfloor + 1$).

Thus, if $\lim_n \frac{\omega_n}{\varepsilon_n} =: c \in \mathbb{R} \cup \{+\infty\}$, then $(\zeta_{p,\varepsilon_n} u)$ and $(\zeta_{p',\varepsilon_n} v)$ form an (ω_n) -pure pair of sequences and the corresponding one-scale H-distribution reads

$$\langle \nu_{K_{0,\infty}}, \Psi \rangle = \langle \vartheta_c, \Psi(\mathbf{z}, \cdot) \rangle, \quad \Psi \in C^{0, \lfloor \frac{d}{2} \rfloor + 1}(\Omega \times K_{0,\infty}(\mathbb{R}^d)).$$

Here we can see that the one-scale H-distribution is a distribution of order $(0, \lfloor \frac{d}{2} \rfloor + 1)$, which is slightly better than the estimate on order provided by Theorem 4.1 (cf. [8]). However, this example shows that one-scale H-distributions are not Radon measures in general (cf. [8, Section 5.2]).

The fact that $\nu_{K_{0,\infty}}$ is, with respect to \mathbf{x} , a constant multiple of the Dirac measure centered at \mathbf{z} is not surprising. Indeed, it is easy to see that after multiplying sequences $(\zeta_{p,\varepsilon_n} u)$ and $(\zeta_{p',\varepsilon_n} v)$ by a smooth cut-off function around an arbitrary neighbourhood of \mathbf{z} , the distribution remains unchanged. Thus, by Corollary 4.4 the distribution is supported with respect to \mathbf{x} in $\{\mathbf{z}\}$, implying that it is a finite sum of multiples of derivatives of the Dirac mass at that point. However, by Theorem 4.1 we know that $\nu_{K_{0,\infty}}$ is of order 0 with respect to \mathbf{x} , which leaves the only possibility that it is a constant multiple of the Dirac measure at \mathbf{z} .

Applying Corollary 4.5 we get that $(\zeta_{p,\varepsilon_n} u)$ and $(\zeta_{p',\varepsilon_n} v)$ form a pure pair and the corresponding H-distribution ν_H is given by

$$\langle \nu_H, \Psi \rangle = \langle \vartheta_1, \Psi(\mathbf{z}, \pi(\cdot)) \rangle = \int_{\mathbb{R}^d} \mathcal{A}_{\Psi(\mathbf{z}, \pi(\cdot))} u(\mathbf{x}) \overline{v(\mathbf{x})} dx, \quad \Psi \in C^{0, \lfloor \frac{d}{2} \rfloor + 1}(\Omega \times S^{d-1}),$$

which agrees with the result obtained in [8, Section 5.1]. We would get the same if we took $c \in \{0, \infty\}$ instead of $c = 1$, since $(\psi \circ \pi)_0 = (\psi \circ \pi)_\infty = \psi$, for $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(S^{d-1})$.

In this example we can see that an advantage of one-scale H-distributions over H-distributions is in the fact that the former contain the information on the characteristic length of sequences.

More precisely, by tuning the characteristic length of one-scale H-distribution (ω_n) we can detect the order of convergence of the characteristic length of the sequence (ε_n) . On the other hand, the H-distribution is the same for any choice of (ε_n) .

Furthermore, we can also see that the opposite implication of the one given in Corollary 4.5 does not hold. Indeed, here we have that sequences $(\zeta_{p,\varepsilon_n} u)$ and $(\zeta_{p',\varepsilon_n} v)$ always form a pure pair (i.e. for any choice of $\varepsilon_n \rightarrow 0^+$ associated H-distribution is unique). However, if $(\frac{\omega_n}{\varepsilon_n})$ does not converge in $\mathbb{R} \cup \{+\infty\}$ (i.e., if it has two or more accumulation points), those sequences are not (ω_n) -pure.

Lemma 4.10. *Let $p \in (1, \infty)$ and let (ψ_n) be a bounded sequence of L^p Fourier multipliers such that it converges almost everywhere to an L^p Fourier multiplier ψ .*

Then for any $u \in L^p(\mathbb{R}^d)$ the sequence $(\mathcal{A}_{\psi_n} u)$ converges weakly to $\mathcal{A}_\psi u$ in $L^p(\mathbb{R}^d)$.

Furthermore, if the assumptions above hold for any $p \in (1, \infty)$, then for any $u \in L^p(\mathbb{R}^d)$ the sequence $(\mathcal{A}_{\psi_n} u)$ converges strongly to $\mathcal{A}_\psi u$ in $L^p(\mathbb{R}^d)$, for any $p \in (1, \infty)$.

Proof. Let $u \in L^p(\mathbb{R}^d)$. By the assumption $(\mathcal{A}_{\psi_n - \psi})$ is a bounded sequence of operators on $L^p(\mathbb{R}^d)$, implying that $(\mathcal{A}_{\psi_n - \psi} u)$ is a bounded sequence in $L^p(\mathbb{R}^d)$. Thus, for the first claim it is sufficient to show that

$$(4.5) \quad (\forall \varphi \in C_c^\infty(\mathbb{R}^d)) \quad {}_{L^{p'}}\langle \varphi, \mathcal{A}_{\psi_n - \psi} u \rangle_{L^p} \longrightarrow 0.$$

For an arbitrary $\varepsilon > 0$, let us take $u_\varepsilon \in C_c^\infty(\mathbb{R}^d)$ such that $\|u - u_\varepsilon\|_{L^p(\mathbb{R}^d)} < \varepsilon$. Since $\|\mathcal{A}_{\psi_n - \psi}(u - u_\varepsilon)\|_{L^p} = O(\varepsilon)$ (the bound is independent of n), we are left to prove (4.5) when u is replaced by u_ε .

By the Plancherel formula it holds

$${}_{L^{p'}}\langle \varphi, \mathcal{A}_{\psi_n - \psi} u_\varepsilon \rangle_{L^p} = \int_{\mathbb{R}^d} \mathcal{A}_{\psi_n - \psi} u_\varepsilon(\mathbf{x}) \bar{\varphi}(\boldsymbol{\xi}) d\mathbf{x} = \int_{\mathbb{R}^d} (\psi_n(\boldsymbol{\xi}) - \psi(\boldsymbol{\xi})) \widehat{u}_\varepsilon(\boldsymbol{\xi}) \overline{\widehat{\varphi}(\boldsymbol{\xi})} d\boldsymbol{\xi}.$$

Therefore, for a fixed ε and φ , by the Lebesgue dominated convergence theorem we have that $\lim_n {}_{L^{p'}}\langle \varphi, \mathcal{A}_{\psi_n - \psi} u_\varepsilon \rangle_{L^p} = 0$.

Assume now that the stronger condition holds, i.e. that for any $p \in (1, \infty)$ the sequence (ψ_n) is a bounded sequence of L^p Fourier multipliers and its pointwise limit ψ is an L^p Fourier multiplier for any $p \in (1, \infty)$, as well. Let $\theta \in (0, 1)$ and $r \in (1, \infty)$ be such that $1/p = \theta/2 + (1 - \theta)/r$ and let u_ε be as above. By the classical interpolation inequality we have

$$\begin{aligned} \|\mathcal{A}_{\psi_n - \psi} u\|_{L^p} &\leq \|\mathcal{A}_{\psi_n - \psi}(u - u_\varepsilon)\|_{L^p} + \|\mathcal{A}_{\psi_n - \psi} u_\varepsilon\|_{L^p} \\ &\leq O(\varepsilon) + \|\mathcal{A}_{\psi_n - \psi} u_\varepsilon\|_{L^2}^\theta \|\mathcal{A}_{\psi_n - \psi} u_\varepsilon\|_{L^r}^{1-\theta}. \end{aligned}$$

Similarly as above, by the Plancherel formula and the Lebesgue dominated convergence theorem we have (for fixed ε) $\lim_n \|\mathcal{A}_{\psi_n - \psi} u_\varepsilon\|_{L^2} = 0$, while $(\|\mathcal{A}_{\psi_n - \psi} u_\varepsilon\|_{L^r})_n$ is bounded since $(\psi_n - \psi)$ is a bounded sequence of L^r Fourier multipliers, and this concludes the proof. \square

Remark 4.11. It can easily be seen from the above proof that the assumption of the second part of the previous lemma can be weakened, while still preserving the strong convergence in the starting $L^p(\mathbb{R}^d)$ space. Namely, if (ψ_n) is a bounded sequence of L^q Fourier multipliers, for $q \in \{p, r\}$, such that it converges almost everywhere to an L^q Fourier multiplier ψ and there exists $\theta \in (0, 1)$ such that $1/p = \theta/2 + (1 - \theta)/r$, then for any $u \in L^p(\mathbb{R}^d)$ the sequence $(\mathcal{A}_{\psi_n} u)$ converges strongly to $\mathcal{A}_\psi u$ in $L^p(\mathbb{R}^d)$.

4.3. Example II: Oscillation. Let $p \in (1, \infty)$, $\mathbf{k} \in \mathbb{R}_*^d$, $\varepsilon_n \rightarrow 0^+$, and $u \in L_{\text{loc}}^p(\mathbb{R}^d)$. We define two sequences

$$u_n(\mathbf{x}) = u(\mathbf{x})e^{2\pi i \frac{\mathbf{x}}{\varepsilon_n} \cdot \mathbf{k}} \quad \text{and} \quad v_n(\mathbf{x}) = |u(\mathbf{x})|^{p-2} u(\mathbf{x}) e^{2\pi i \frac{\mathbf{x}}{\varepsilon_n} \cdot \mathbf{k}},$$

which are weakly converging to 0 in $L_{\text{loc}}^p(\mathbb{R}^d)$ and $L_{\text{loc}}^{p'}(\mathbb{R}^d)$, respectively.

For an arbitrary $\omega_n \rightarrow 0^+$ let us derive the formula for the one-scale H-distribution with characteristic length (ω_n) associated to the pair of sequences $(u_n), (v_n)$.

Take $\varphi_1, \varphi_2 \in C_c(\mathbb{R}^d)$ and $\psi \in C^{\lfloor \frac{d}{2} \rfloor + 1}(\mathbb{K}_{0, \infty}(\mathbb{R}^d))$. Using the following property of Fourier multipliers

$$(4.6) \quad \mathcal{A}_\psi(e^{2\pi i \cdot \mathbf{k}} f) = e^{2\pi i \cdot \mathbf{k}} \mathcal{A}_{\psi(\cdot + \mathbf{k})} f$$

we get

$$\int_{\mathbb{R}^d} \mathcal{A}_{\psi(\omega_n \cdot)}(\varphi_1 u_n)(\mathbf{x}) \overline{\varphi_2(\mathbf{x}) v_n(\mathbf{x})} d\mathbf{x} = \int_{\mathbb{R}^d} \mathcal{A}_{\psi(\omega_n \cdot + \frac{\omega_n}{\varepsilon_n} \mathbf{k})}(\varphi_1 u)(\mathbf{x}) \overline{\varphi_2(\mathbf{x}) |u(\mathbf{x})|^{p-2} u(\mathbf{x})} d\mathbf{x}.$$

For the moment assume that the sequence of positive numbers $(\frac{\omega_n}{\varepsilon_n})$ converges in $\mathbb{R} \cup \{+\infty\}$. Then by lemmata 2.12 and 4.10 we can pass to the limit in the expression above. More precisely, by Corollary 2.4 for fixed $\boldsymbol{\xi} \in \mathbb{R}_*^d$ we have

$$\psi\left(\omega_n \boldsymbol{\xi} + \frac{\omega_n}{\varepsilon_n} \mathbf{k}\right) \longrightarrow \begin{cases} \psi_0\left(\frac{\mathbf{k}}{|\mathbf{k}|}\right), & \lim_n \frac{\omega_n}{\varepsilon_n} = 0 \\ \psi(c\mathbf{k}), & \lim_n \frac{\omega_n}{\varepsilon_n} = c \in (0, \infty) \\ \psi_\infty\left(\frac{\mathbf{k}}{|\mathbf{k}|}\right), & \lim_n \frac{\omega_n}{\varepsilon_n} = \infty \end{cases}.$$

Therefore, we can conclude that the unique one-scale H-distribution is given by

$$\nu_{\mathbb{K}_{0, \infty}}^{(\omega_n)} = |u|^p \lambda \otimes \begin{cases} \delta_{0 \frac{\mathbf{k}}{|\mathbf{k}|}}, & \lim_n \frac{\omega_n}{\varepsilon_n} = 0 \\ \delta_{c\mathbf{k}}, & \lim_n \frac{\omega_n}{\varepsilon_n} = c \in (0, \infty) \\ \delta_{\infty \frac{\mathbf{k}}{|\mathbf{k}|}}, & \lim_n \frac{\omega_n}{\varepsilon_n} = \infty, \end{cases}$$

where by λ we denoted the Lebesgue measure on \mathbb{R}^d . Thus, in this example the one-scale H-distributions are in fact Radon measures (distributions of order zero), which is *not* the case for all one-scale H-distributions (see the previous example). Moreover, their form is the same for any $p \in (1, \infty)$ (cf. [7, Example 4] for the case $p = 2$).

In general, the sequence $(\frac{\omega_n}{\varepsilon_n})$ can have more than one accumulation point (in $\mathbb{R} \cup \{+\infty\}$). Then the pair $(u_n), (v_n)$ is not (ω_n) -pure, and the corresponding one-scale H-distribution is of one of the above three forms.

However, by Corollary 4.5 we have that the pair $(u_n), (v_n)$ is pure, and the corresponding H-distribution ν_H reads

$$\nu_H = |u|^p \lambda \otimes \delta_{\frac{\mathbf{k}}{|\mathbf{k}|}},$$

so it is a Radon measure as well.

4.4. Semiclassical pseudodifferential operators and the Wigner transform. In the L^2 -setting ($p = 2$) one gets semiclassical measures when the space of test functions in the dual space $C^\kappa(\mathbb{K}_{0, \infty}(\mathbb{R}^d))$ is replaced by $\mathcal{S}(\mathbb{R}^d)$ [7, Corollary 6]. More precisely, semiclassical measures are restrictions of one-scale H-measures to $\Omega \times \mathbb{R}^d$. This motivates the introduction of the following generalisation of semiclassical measures (for simplicity, we take the second sequence only in L^p based spaces, and we do not consider a minor generalisation obtained by taking $q \geq p'$ here).

Definition 4.12. For $\Omega \subseteq \mathbb{R}^d$ open and $p \in (1, \infty)$ let (u_n) and (v_n) be sequences bounded in $L^p_{\text{loc}}(\Omega)$ and $L^{p'}_{\text{loc}}(\Omega)$, respectively, and let $\omega_n \rightarrow 0^+$.

A distribution $\nu_{sc} \in \mathcal{D}'_{0,\kappa}(\Omega \times \mathbb{R}^d)$, where $\kappa := d(\lfloor \frac{d}{2} \rfloor + 3)$, we call the *semiclassical distribution* (with characteristic length $(\omega_{n'})$) associated to (sub)sequences $(u_{n'})$ and $(v_{n'})$ if for any $\varphi_1, \varphi_2 \in C_c(\Omega)$ and $\psi \in \mathcal{S}(\mathbb{R}^d)$ we have

$$\lim_{n' \rightarrow \infty} \int_{\mathbb{R}^d} \mathcal{A}_{\psi_{n'}}(\varphi_1 u_{n'})(\mathbf{x}) \overline{(\varphi_2 v_{n'})(\mathbf{x})} d\mathbf{x} = \left\langle \nu_{sc}^{(\omega_{n'})}, \varphi_1 \bar{\varphi}_2 \otimes \psi \right\rangle,$$

where $\psi_n := \psi(\omega_n \cdot)$.

The existence of subsequences referred to above follows from Theorem 4.1 and Remark 4.2.

It should be mentioned that the semiclassical measures were first introduced by Gérard [33] using semiclassical pseudodifferential operators, while an alternative construction was obtained by Lions and Paul [50] in terms of the Wigner transform. Moreover, they are presumably better known nowadays as Wigner measures, since the Wigner transform is a very popular tool in mathematical physics. However, both these approaches were confined to the L^2 setting, hence here we present their generalisation to the $L^p - L^{p'}$ framework. Moreover, we shall see that the resulting object indeed coincides with the above introduced semiclassical distributions, thus justifying the name.

We start by recalling some well known results from the theory of (semiclassical) pseudodifferential operators for which we mainly follow [67] (see also [66]).

For $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, $\omega \in (0, 1]$ and $t \in [0, 1]$ we define the semiclassical pseudodifferential operator in t -quantisation to be the operator $\text{Op}_t^{(\omega)}(a)$ acting on $u \in \mathcal{S}(\mathbb{R}^d)$ by formula

$$\begin{aligned} \text{Op}_t^{(\omega)}(a)u(\mathbf{x}) &= \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} e^{2\pi i(\mathbf{x}-\mathbf{y}) \cdot \boldsymbol{\xi}} a(t\mathbf{x} + (1-t)\mathbf{y}, \omega\boldsymbol{\xi}) u(\mathbf{y}) d\mathbf{y} d\boldsymbol{\xi} \\ &= \omega^{-d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} e^{\frac{2\pi i}{\omega}(\mathbf{x}-\mathbf{y}) \cdot \boldsymbol{\eta}} a(t\mathbf{x} + (1-t)\mathbf{y}, \boldsymbol{\eta}) u(\mathbf{y}) d\mathbf{y} d\boldsymbol{\eta}, \end{aligned}$$

where the second equality is due to the change of variables $\boldsymbol{\eta} = \omega\boldsymbol{\xi}$. Let us note that in this paper we use a different definition of the Fourier transform than in [67], and consequentially the above definition slightly differs as well. For $t = \frac{1}{2}$ we get the Weyl quantisation and for $t = 1$ the standard (Kohn-Nirenberg) quantisation, while the common notation for these cases is

$$a^w(\mathbf{x}, \omega D) = \text{Op}_{\frac{1}{2}}^{(\omega)} \quad \text{and} \quad a(\mathbf{x}, \omega D) = \text{Op}_1^{(\omega)}.$$

If the symbol a does not depend on \mathbf{x} , i.e. $a = a(\boldsymbol{\xi})$, then the above operators are just Fourier multipliers. More precisely, for any $t \in [0, 1]$ we have $\text{Op}_t^{(\omega)}(a) = \mathcal{A}_{a(\omega \cdot)}$. On the other hand, if a does not depend on $\boldsymbol{\xi}$, i.e. $a = a(\mathbf{x})$, then the above operator for $t = 1$ simplifies to the operator of multiplication by a , i.e. $\text{Op}_1^{(\omega)}(a)u(\mathbf{x}) = a(\mathbf{x})u(\mathbf{x})$.

A very useful conversion formula between different quantisations holds: if

$$\text{Op}_t^{(\omega)}(a_t) = \text{Op}_s^{(\omega)}(a_s)$$

for $t, s \in [0, 1]$ and $a_t, a_s \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, then

$$a_t(\mathbf{x}, \boldsymbol{\xi}) = e^{\frac{2\pi i}{\omega}(t-s)(\omega D_{\mathbf{x}}) \cdot (\omega D_{\boldsymbol{\xi}})} a_s(\mathbf{x}, \boldsymbol{\xi}).$$

By [67, theorems 3.17(i) and 4.8(ii)], from the above one can deduce that there exists $b^{(\omega)} \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, which is bounded with respect to ω , such that

$$(4.7) \quad a_t = a_s + \omega b^{(\omega)} .$$

For any $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ and $t \in [0, 1]$, $\text{Op}_t^{(\omega)}(a)$ can be extended to a continuous linear operator from $\mathcal{S}'(\mathbb{R}^d)$ to $\mathcal{S}'(\mathbb{R}^d)$. Here we are particularly interested in their restrictions to L^p spaces, $p \in (1, \infty)$. More precisely, for any $p \in (1, \infty)$ there exists a $C > 0$ and multiindices $\alpha, \beta \in \mathbb{N}_0^{2d}$, depending only on p and d , such that for any $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, $t \in [0, 1]$ and $\omega \in (0, 1]$ it holds

$$(4.8) \quad \|\text{Op}_t^{(\omega)}(a)\|_{\mathcal{L}(L^p(\mathbb{R}^d))} \leq C|a|_{\alpha, \beta} + O(\omega) ,$$

as $\omega \rightarrow 0^+$, where $|a|_{\alpha, \beta} = \sup_{\mathbb{R}^{2n}} |\mathbf{x}^\alpha \partial^\beta a|$ are the standard seminorms used in the definition of the Schwartz space $\mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$.

A very simple proof of this statement can be found in [42, Lemma 2.2] for the standard quantisation, which can be used, together with the above conversion formula, to prove the result for general t . Moreover, by (4.7) we have

$$(4.9) \quad \lim_{\omega \rightarrow 0^+} \|\text{Op}_t^{(\omega)}(a) - \text{Op}_s^{(\omega)}(a)\|_{\mathcal{L}(L^p(\mathbb{R}^d))} = 0 .$$

The commutator of two semiclassical pseudodifferential operators (in the same quantisation) vanishes as ω approaches zero, i.e. for any $a, b \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ it holds

$$(4.10) \quad \lim_{\omega \rightarrow 0^+} \|[\text{Op}_t^{(\omega)}(a), \text{Op}_t^{(\omega)}(b)]\|_{\mathcal{L}(L^p(\mathbb{R}^d))} = 0 .$$

This is due to the fact that the symbol of composition $\text{Op}_t^{(\omega)}(a) \text{Op}_t^{(\omega)}(b)$ is equal to $ab + \omega c^{(\omega)}$, where $c^{(\omega)} \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ is bounded with respect to ω .

Now we use the approach of semiclassical pseudodifferential operators in the study of weakly converging sequences in the $L^p - L^{p'}$ setting, $1/p + 1/p' = 1$ (as it has already been done in Definition 4.12).

For simplicity of the exposition, in the remaining part of this subsection, we shall consider a more specific situation than in Definition 4.12: let (u_n) and (v_n) be bounded sequences in $L^p(\mathbb{R}^d)$ and $L^{p'}(\mathbb{R}^d)$, respectively, and let $\omega_n \rightarrow 0^+$.

Take any $t \in [0, 1]$. First we consider an arbitrary a from a countable dense subset \mathcal{G} of $\mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ (the separability of the Schwartz space is a well-known result). By (4.8) the sequence ${}_{L^p} \langle \text{Op}_t^{(\omega_n)}(a) u_n, \bar{v}_n \rangle_{L^{p'}}$ is bounded, thus admitting a converging subsequence, which by the diagonal argument we can take to be the same for any $a \in \mathcal{G}$. For simplicity, we do not relabel the subsequence. At this moment we have that $\lim_n {}_{L^p} \langle \text{Op}_t^{(\omega_n)}(\cdot) u_n, \bar{v}_n \rangle_{L^{p'}}$ is a linear functional on \mathcal{G} . Again, by using (4.8) we can see that it is in fact bounded on $\mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$. Thus, $\tilde{\nu}_{sc} := \lim_n {}_{L^p} \langle \text{Op}_t^{(\omega_n)}(\cdot) u_n, \bar{v}_n \rangle_{L^{p'}} \in \mathcal{S}'(\mathbb{R}^d \times \mathbb{R}^d)$. It is important to notice that by (4.9) the distribution $\tilde{\nu}_{sc}$ does not depend on t .

We shall prove that $\tilde{\nu}_{sc}$ coincides with the distribution given in Definition 4.12.

Let us assume that defining subsequences for distributions ν_{sc} and $\tilde{\nu}_{sc}$ are the same (otherwise we first pass to subsequences in order to define ν_{sc} and then we apply the above procedure for $\tilde{\nu}_{sc}$ on that pair of subsequences). Consider those subsequences and denote them by (u_n) , (v_n)

and (ω_n) . For any $\varphi_1, \varphi_2 \in C_c^\infty(\mathbb{R}^d)$ and $\psi \in \mathcal{S}(\mathbb{R}^d)$ we have

$$\begin{aligned} \langle \nu_{sc}, \varphi_1 \bar{\varphi}_2 \otimes \psi \rangle &= \lim_{n \rightarrow \infty} \int_{\mathbb{R}^d} \mathcal{A}_{\psi_n}(\varphi_1 u_n)(\mathbf{x}) \overline{(\varphi_2 v_n)(\mathbf{x})} d\mathbf{x} \\ &= \lim_{n \rightarrow \infty} \int \text{Op}_1^{(\omega_n)}(\bar{\varphi}_2) \text{Op}_1^{(\omega_n)}(\psi) \text{Op}_1^{(\omega_n)}(\varphi_1)(u_n)(\mathbf{x}) \overline{v_n(\mathbf{x})} d\mathbf{x} \\ &= \lim_{n \rightarrow \infty} \int \text{Op}_1^{(\omega_n)}(\varphi_1 \bar{\varphi}_2 \otimes \psi)(u_n)(\mathbf{x}) \overline{v_n(\mathbf{x})} d\mathbf{x} \\ &= \langle \tilde{\nu}_{sc}, \varphi_1 \bar{\varphi}_2 \otimes \psi \rangle, \end{aligned}$$

where in the third equality we have used (4.10). Hence, since tensor products are dense in $\mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, we get $\nu_{sc} = \tilde{\nu}_{sc}$.

Another approach in studying microlocal defect objects associated to weakly converging sequences is to consider the Wigner transform, which in t -quantisation we define by

$$W_t^{(\omega)}(u, v)(\mathbf{x}, \boldsymbol{\xi}) = \int_{\mathbb{R}^d} e^{-2\pi i \mathbf{y} \cdot \boldsymbol{\xi}} u(x + \omega t \mathbf{y}) \overline{v(\mathbf{x} - \omega(1-t)\mathbf{y})} d\mathbf{y},$$

where we take $u \in L^p(\mathbb{R}^d)$ and $v \in L^{p'}(\mathbb{R}^d)$, $p \in (1, \infty)$. The case $t = \frac{1}{2}$ is the most common, and often only that case is considered in the literature. For any $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ we have

$$\begin{aligned} \mathcal{S} \langle W_t^{(\omega)}(u, v), a \rangle_{\mathcal{S}} &= \iiint_{\mathbb{R}^{3d}} e^{-2\pi i \mathbf{y} \cdot \boldsymbol{\xi}} u(x + \omega t \mathbf{y}) \overline{v(\mathbf{x} - \omega(1-t)\mathbf{y})} a(\mathbf{x}, \boldsymbol{\xi}) d\mathbf{y} d\mathbf{x} d\boldsymbol{\xi} \\ &= \iiint_{\mathbb{R}^{3d}} e^{2\pi i (\mathbf{x}' - \mathbf{y}') \cdot \boldsymbol{\xi}'} u(\mathbf{y}') \overline{v(\mathbf{x}')} a(t\mathbf{x}' + (1-t)\mathbf{y}', \omega \boldsymbol{\xi}') d\mathbf{y}' d\mathbf{x}' d\boldsymbol{\xi}' \\ &= {}_{L^p} \langle \text{Op}_t^{(\omega)}(a)u, \bar{v} \rangle_{L^{p'}}, \end{aligned}$$

where in the second equality we have applied the change of variables: $\mathbf{x}' = \mathbf{x} - \omega(1-t)\mathbf{y}$, $\mathbf{y}' = \mathbf{x} + \omega t \mathbf{y}$, $\boldsymbol{\xi}' = \frac{1}{\omega} \boldsymbol{\xi}$, having the Jacobian equal to 1. Thus, the Wigner transform in t -quantisation is connected to the t -quantisation of semiclassical pseudodifferential operators.

Therefore, for the above choice of sequences (u_n) , (v_n) and (ω_n) , we have obtained

$$\begin{aligned} \langle \nu_{sc}, a \rangle &= \lim_n {}_{L^p} \langle \text{Op}_t^{(\omega_n)}(a)u_n, \bar{v}_n \rangle_{L^{p'}} \\ &= \lim_n \mathcal{S} \langle W_t^{(\omega_n)}(u_n, v_n), a \rangle_{\mathcal{S}}, \end{aligned}$$

for any $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$, showing that all the above described approaches lead to the same object, as it was the case in the L^2 setting.

A short note on the definition of semiclassical distributions in terms of the Wigner transform can be found in [9].

Remark 4.13. In this subsection the study of the limit of $W^{(\omega_n)}(u_n, v_n)$ was conducted using the relation between the Wigner transform and the semiclassical pseudodifferential operators. Historically [50], in the L^2 case the study was made directly by using the Husimi transform, which has some benefits of its own (see also [66]).

5. LOCALISATION PRINCIPLE FOR ONE-SCALE H-DISTRIBUTIONS

We have seen that one-scale H-distributions are a suitable tool for studying strong compactness of weakly converging sequences, where sequences determining zero one-scale H-distribution

have a desirable property (see Lemma 4.6). Our goal is to extract as much information as possible about one-scale H-distributions from the observed sequences.

In this section we study weakly converging sequences which satisfy some linear partial differential relations with variable coefficients. More precisely, we consider a sequence of systems of partial differential equations in divergence form of order $m \in \mathbb{N}$ with a characteristic length (ε_n)

$$(5.1) \quad \sum_{|\alpha| \leq m} \varepsilon_n^{|\alpha|} \partial_\alpha (\mathbf{A}_n^\alpha \mathbf{u}_n) = \mathbf{f}_n,$$

where \mathbf{A}_n^α are given matrices of (variable) coefficients. Since we assume that a sequence of solutions (\mathbf{u}_n) to (5.1) is given, the relation above could serve as a definition of the right hand side \mathbf{f}_n . Moreover, as it will be seen below, for the sequence (\mathbf{f}_n) it is only important that it satisfies certain compactness properties.

Equations of the form (5.1) often appear when modelling highly oscillating problems (e.g. the passage from micro- to meso- or macro-scale, the semiclassical limit or some scaling suitable for a particular physical model). A more precise list of related problems with selected references can be found in the Introduction.

In [7, Section 4] this problem was treated in the L^2 framework, while here we present a generalisation to the L^p setting, for $p \in (1, \infty)$.

5.1. Right hand side. Let $s \in \mathbb{R}$, $p \in (1, \infty)$ and $d, r \in \mathbb{N}$ be given. The Sobolev space $W^{s,p}(\mathbb{R}^d; \mathbb{C}^r)$ we define by

$$W^{s,p}(\mathbb{R}^d; \mathbb{C}^r) := \left\{ \mathbf{f} \in \mathcal{S}'(\mathbb{R}^d; \mathbb{C}^r) : \mathcal{A}_{(1+|\xi|^2)^{\frac{s}{2}}} \mathbf{f} \in L^p(\mathbb{R}^d; \mathbb{C}^r) \right\}.$$

It is a vector space, and equipped with the norm $\|\mathbf{f}\|_{W^{s,p}(\mathbb{R}^d; \mathbb{C}^r)} := \|\mathcal{A}_{(1+|\xi|^2)^{\frac{s}{2}}} \mathbf{f}\|_{L^p(\mathbb{R}^d; \mathbb{C}^r)}$ it becomes a Banach space. This definition via Fourier multipliers coincides with the standard one in terms of weak derivatives (cf. [37, Section 6.2]).

Moreover, in both definitions, of the space and of the norm, the symbol $\xi \mapsto (1 + |\xi|^2)^{\frac{s}{2}}$ can be replaced by $\xi \mapsto (1 + |\xi|^{2s})^{\frac{1}{2}}$, which is the form we shall use in the rest of the paper. One just has to be aware that the latter symbol is not smooth around the origin (cf. [40, Section 10.1]). Another way to see this equivalence is by applying Corollary 2.6(iv) and Theorem 2.9.

The local Sobolev spaces are naturally defined in the following manner:

$$W_{\text{loc}}^{s,p}(\Omega; \mathbb{C}^r) := \left\{ \mathbf{f} \in \mathcal{D}'(\Omega; \mathbb{C}^r) : (\forall \varphi \in C_c^\infty(\Omega)) \varphi \mathbf{f} \in W^{s,p}(\mathbb{R}^d; \mathbb{C}^r) \right\},$$

where we assume identification of functions on Ω with their extension by zero to the whole \mathbb{R}^d . When equipped with the weakest topology in which every mapping $\mathbf{f} \mapsto \varphi \mathbf{f}$ from $W_{\text{loc}}^{s,p}(\Omega; \mathbb{C}^r)$ to $W^{s,p}(\mathbb{R}^d; \mathbb{C}^r)$ is continuous, $W_{\text{loc}}^{s,p}(\Omega; \mathbb{C}^r)$ becomes a Fréchet space (cf. [64, Chapter 31]). In fact, the seminorms are of the form $\|\varphi \mathbf{f}\|_{W^{s,p}(\mathbb{R}^d; \mathbb{C}^r)}$, and one can take φ only from a suitable countable family [5].

Let us return to (5.1). Since on the left hand side we have a differential operator of order m , for $u \in L^p$ the best we can expect in general for the right hand side is that it belongs to $W^{-m,p}$. However, instead of the standard strong topology, it is natural to include the characteristic length (ε_n) in the compactness condition for (\mathbf{f}_n) . Namely, for a sequence of positive numbers (ε_n) we say that a sequence (\mathbf{f}_n) in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$ satisfies the (ε_n) -compactness condition if the following strong convergence holds:

$$(5.2) \quad \mathcal{A}_{\frac{1}{1+\varepsilon_n \xi^{2m}}} \mathbf{f}_n \longrightarrow 0 \quad \text{in } L^p(\mathbb{R}^d; \mathbb{C}^r).$$

If all f_n belong only to $W_{\text{loc}}^{-m,p}(\Omega; \mathbb{C}^r)$, then the condition above is naturally replaced by its local version:

$$(5.3) \quad (\forall \varphi \in C_c^\infty(\Omega)) \quad \mathcal{A}_{\frac{1}{1+|\varepsilon_n \boldsymbol{\xi}|^m}}(\varphi f_n) \longrightarrow 0 \quad \text{in} \quad L^p(\mathbb{R}^d; \mathbb{C}^r),$$

which we baptise the (ε_n) -local compactness condition. In both conditions (5.2) and (5.3) we can replace the symbol $\boldsymbol{\xi} \mapsto (1 + |\varepsilon_n \boldsymbol{\xi}|^m)^{-1}$ by $\boldsymbol{\xi} \mapsto (1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{-m/2}$, similarly as we did in the already discussed situation regarding the Sobolev norms. This can be justified by means of Corollary 2.6(iv), Theorem 2.9 and Lemma 2.12.

Remark 5.1. In the case $p = 2$ Plancherel's theorem holds, so the conditions (5.2) and (5.3) can be expressed merely in terms of the Fourier transform. This was precisely the approach used in [62, Chapter 32] and [7] (see conditions (32.25) and (4.3) in the aforementioned references, respectively).

It is evident that for a stationary sequence $\varepsilon_n = \varepsilon > 0$ the conditions (5.2) and (5.3) are equivalent to the strong convergences to zero of (f_n) in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$ and $W_{\text{loc}}^{-m,p}(\Omega; \mathbb{C}^r)$, respectively. A more precise description of these conditions is given in the following lemma.

Lemma 5.2. *Let $m \in \mathbb{N}$ and $p \in (1, \infty)$, and let (ε_n) and (ω_n) be sequences of positive real numbers.*

- i) *If $\liminf_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n} > 0$, then the (ε_n) -compactness implies (ω_n) -compactness.*
- ii) *If $\limsup_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n} < \infty$, then the (ω_n) -compactness implies (ε_n) -compactness.*

Proof. Let us notice first that it is sufficient to prove only one statement (say (i)), since by interchanging the roles of (ε_n) and (ω_n) we infer the second statement from it.

Let $\liminf_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n} > 0$ and assume that for a sequence (f_n) in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$ the (ε_n) -compactness holds. We set $c_0 = \liminf_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n}$ if $\liminf_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n} < \infty$, and $c_0 = 1$ in the case $\liminf_{n \rightarrow \infty} \frac{\omega_n}{\varepsilon_n} = \infty$. Then there exists $n_0 \in \mathbb{N}$ such that for any $n \geq n_0$ one has $\omega_n \geq \frac{c_0}{2} \varepsilon_n$.

By using

$$\frac{1}{1 + |\omega_n \boldsymbol{\xi}|^m} = \frac{1 + |\varepsilon_n \boldsymbol{\xi}|^m}{1 + |\omega_n \boldsymbol{\xi}|^m} \frac{1}{1 + |\varepsilon_n \boldsymbol{\xi}|^m},$$

and the composition rule for Fourier multipliers $\mathcal{A}_{\psi_1 \psi_2} = \mathcal{A}_{\psi_1} \mathcal{A}_{\psi_2}$, it is sufficient to prove that $\left(\frac{1 + |\varepsilon_n \boldsymbol{\xi}|^m}{1 + |\omega_n \boldsymbol{\xi}|^m} \right)_n$ is a bounded sequence of L^p Fourier multipliers. Indeed, we have

$$\frac{1 + |\varepsilon_n \boldsymbol{\xi}|^m}{1 + |\omega_n \boldsymbol{\xi}|^m} = \left(\frac{\varepsilon_n}{\omega_n} \right)^m + \frac{1 - \left(\frac{\varepsilon_n}{\omega_n} \right)^m}{1 + |\omega_n \boldsymbol{\xi}|^m}.$$

Now the claim is obvious since $\frac{\varepsilon_n}{\omega_n} \leq \frac{2}{c_0}$, $|1 - \left(\frac{\varepsilon_n}{\omega_n} \right)^m| \leq \max\{1, \left(\frac{2}{c_0} \right)^m - 1\}$, and by Corollary 2.6(iii), Theorem 2.9 and Lemma 2.12 we have that $\left(\frac{1}{1 + |\omega_n \boldsymbol{\xi}|^m} \right)_n$ is a bounded sequence of L^p Fourier multipliers. \square

For the stationary sequence $\omega_n = 1$ we have that (ω_n) -compactness is equivalent to the strong convergence to zero in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$, from the previous lemma we immediately get the following corollary.

Corollary 5.3. *Let $m \in \mathbb{N}$ and $p \in (1, \infty)$, and let (ε_n) be a sequence of positive real numbers.*

- i) *If $\limsup_{n \rightarrow \infty} \varepsilon_n = \varepsilon_\infty < \infty$, then (ε_n) -compactness implies the strong convergence to zero in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$.*

- ii) If $\liminf_{n \rightarrow \infty} \varepsilon_n = c_\infty < \infty$, then the strong convergence to zero in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$ implies (ε_n) -compactness.

We are particularly interested in the case when $\varepsilon_n \rightarrow 0^+$. By Corollary 5.3, in this case (5.2) is a stronger condition than the strong convergence to zero in $W^{-m,p}(\mathbb{R}^d; \mathbb{C}^r)$.

On the other hand, since $(\frac{1}{1+|\varepsilon_n \boldsymbol{\xi}|^m})_n$ is a bounded sequence of L^p Fourier multipliers, the strong convergence to zero in L^p always implies (5.2). Here we present a procedure how to modify a strongly convergent sequence in a Sobolev space to satisfy (5.2) in the regime of a bounded characteristic length (ε_n) .

Lemma 5.4. *Let (ε_n) be a sequence of positive real numbers bounded from above, let $k \in \{0, 1, \dots, m\}$ and let (f_n) be a sequence of vector valued functions in $W^{-k,p}(\mathbb{R}^d; \mathbb{C}^r)$ which converges strongly to zero. Then $(\varepsilon_n^k f_n)$ satisfies (5.2).*

Proof. Let us first note that by an application of Corollary 2.6(iii,iv) and Lemma 2.12, we can replace the symbol in (5.2) by $\boldsymbol{\xi} \mapsto (1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{-m/2}$.

Now we have

$$\begin{aligned} \frac{\varepsilon_n^k}{(1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{\frac{m}{2}}} &= \left(\frac{\varepsilon_n^2 + |\varepsilon_n \boldsymbol{\xi}|^2}{1 + |\varepsilon_n \boldsymbol{\xi}|^2} \right)^{\frac{k}{2}} \frac{1}{(1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{\frac{m-k}{2}}} \frac{1}{(1 + |\boldsymbol{\xi}|^2)^{\frac{k}{2}}} \\ &=: \psi_1(\varepsilon_n \boldsymbol{\xi}) \psi_2(\varepsilon_n \boldsymbol{\xi}) \psi_3(\boldsymbol{\xi}). \end{aligned}$$

By the assumption we have that $\mathcal{A}_{\psi_3} f_n$ converges strongly to zero in L^p , while $\psi_2(\varepsilon_n \cdot)$ is a bounded sequence of L^p Fourier multipliers (see Corollary 2.6(iii,iv), Theorem 2.9 and Lemma 2.12). Since $\mathcal{A}_{\psi_1(\varepsilon_n \cdot) \psi_2(\varepsilon_n \cdot) \psi_3} = \mathcal{A}_{\psi_1(\varepsilon_n \cdot)} \mathcal{A}_{\psi_2(\varepsilon_n \cdot)} \mathcal{A}_{\psi_3}$, it is only left to see that $\psi_1(\varepsilon_n \cdot)$ is a bounded sequence of L^p Fourier multipliers as well.

After expanding ψ_1 into factors

$$\begin{aligned} \psi_1(\varepsilon_n \boldsymbol{\xi}) &= \frac{(1 + |\boldsymbol{\xi}|^2)^{\frac{k}{2}}}{1 + |\boldsymbol{\xi}|^k} \frac{1 + |\varepsilon_n \boldsymbol{\xi}|^k}{(1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{\frac{k}{2}}} \frac{\varepsilon_n^k + |\varepsilon_n \boldsymbol{\xi}|^k}{1 + |\varepsilon_n \boldsymbol{\xi}|^k} \\ &= \frac{(1 + |\boldsymbol{\xi}|^2)^{\frac{k}{2}}}{1 + |\boldsymbol{\xi}|^k} \frac{1 + |\varepsilon_n \boldsymbol{\xi}|^k}{(1 + |\varepsilon_n \boldsymbol{\xi}|^2)^{\frac{k}{2}}} \left(1 + \frac{\varepsilon_n^k - 1}{1 + |\varepsilon_n \boldsymbol{\xi}|^k} \right), \end{aligned}$$

the claim follows by Corollary 2.6(iii, iv), Theorem 2.9, Lemma 2.12, and the boundedness of (ε_n) . \square

Let us close this subsection by two examples of weakly (but not strongly) converging sequences in L^p space, satisfying the (ε_n) -local compactness condition.

Example 5.5. Let (ε_n) be a sequence of positive real numbers, $p \in (1, \infty)$, $m \in \mathbb{N}$ and $r = 1$.

- i) For $\mathbf{z} \in \mathbb{R}^d$ let $\zeta_{p,\varepsilon}$ be defined as in Subsection 4.2 (recall that it depends on \mathbf{z} , even though it is not explicitly included in the notation).

For an arbitrary $u \in L^p(\mathbb{R}^d)$, $u \neq 0$ and $\omega_n \rightarrow 0^+$, let us see under which conditions on (ω_n) the sequence $(\zeta_{p,\omega_n} u)$ satisfies the (ε_n) -local compactness condition.

By Lemma 4.8 our task is equivalent to examining the (ε_n) -compactness condition, while by Lemma 4.9 we have

$$\left\| \mathcal{A}_{\frac{1}{1+|\varepsilon_n \boldsymbol{\xi}|^m}} \zeta_{p,\omega_n} u \right\|_{L^p} = \left\| \mathcal{A}_{\frac{1}{1+\frac{\varepsilon_n}{\omega_n} |\boldsymbol{\xi}|^m}} u \right\|_{L^p}.$$

If $c := \lim_n \frac{\varepsilon_n}{\omega_n}$ exists in $[0, \infty]$, then for a fixed $\xi \in \mathbb{R}_*^d$ we have

$$\lim_n \frac{1}{1 + \left| \frac{\varepsilon_n}{\omega_n} \xi \right|^m} = \begin{cases} \frac{1}{1 + |c\xi|^m}, & c \in [0, \infty) \\ 0, & c = \infty \end{cases}.$$

Therefore, by Corollary 2.6(iii), Theorem 2.9 and Lemma 2.12, the assumptions of Lemma 4.10 are fulfilled, implying

$$\lim_n \left\| \mathcal{A}_{\frac{1}{1 + \left| \frac{\varepsilon_n}{\omega_n} \xi \right|^m}} u \right\|_{L^p} = \begin{cases} \left\| \mathcal{A}_{\frac{1}{1 + |c\xi|^m}} u \right\|_{L^p}, & c \in [0, \infty) \\ 0, & c = \infty \end{cases}.$$

Hence, the sequence $(\zeta_{p, \omega_n} u)$ satisfies (ε_n) -(local) compactness condition if and only if $\lim_n \frac{\varepsilon_n}{\omega_n} = \infty$.

In a special case when $0 < \liminf_n \varepsilon_n \leq \limsup_n \varepsilon_n < \infty$, this result implies that $(\zeta_{p, \omega_n} u)$ converges strongly to zero in $W^{-m, p}(\mathbb{R}^d)$ (see Corollary 5.3), which is a well known fact (under the assumption of uniformly bounded support, or if one uses the local spaces), since the sequence converges weakly to zero in $L^p(\mathbb{R}^d)$.

ii) Let $\mathbf{k} \in \mathbb{R}_*^d$, $\omega_n \rightarrow 0^+$ and $u \in L_{\text{loc}}^p(\mathbb{R}^d)$, $u \neq 0$, and consider

$$u_n(\mathbf{x}) = u(\mathbf{x}) e^{2\pi i \frac{\mathbf{x} \cdot \mathbf{k}}{\omega_n}}.$$

By (4.6) we have

$$\left\| \mathcal{A}_{\frac{1}{1 + |\varepsilon_n \xi|^m}} (\varphi u_n) \right\|_{L^p} = \left\| \mathcal{A}_{\frac{1}{1 + |\varepsilon_n \xi + \frac{\varepsilon_n}{\omega_n} \mathbf{k}|^m}} (\varphi u) \right\|_{L^p},$$

where $\varphi \in C_c^\infty(\mathbb{R}^d)$ is arbitrary. As in the first example, our aim is to apply Lemma 4.10.

Firstly, let us notice that for any $r \in (1, \infty)$ the sequence of functions $\frac{1}{1 + |\varepsilon_n \xi + \frac{\varepsilon_n}{\omega_n} \mathbf{k}|^m}$ defines a bounded sequence of L^r Fourier multipliers. Indeed, the claim follows by Corollary 2.6(iii), Theorem 2.9, Lemma 2.12, and the fact that Fourier multipliers are invariant under translations (see [36, Proposition 2.5.14]).

It remains to study the pointwise limit of the sequence of symbols. To this end, let us assume that $c := \lim_n \frac{\varepsilon_n}{\omega_n}$ exists in $[0, \infty]$. Thus, for a fixed $\xi \in \mathbb{R}^d$ we have

$$\lim_n \frac{1}{1 + \left| \varepsilon_n \xi + \frac{\varepsilon_n}{\omega_n} \mathbf{k} \right|^m} = \begin{cases} \frac{1}{1 + |c\xi + \mathbf{k}|^m}, & c \in [0, \infty) \\ 0, & c = \infty \end{cases}.$$

Therefore, by Lemma 4.10 we get

$$\lim_n \left\| \mathcal{A}_{\frac{1}{1 + \left| \varepsilon_n \xi + \frac{\varepsilon_n}{\omega_n} \mathbf{k} \right|^m}} (\varphi u) \right\|_{L^p} = \begin{cases} \frac{\|u\|_{L^p}}{1 + |c\xi + \mathbf{k}|^m}, & c \in [0, \infty) \\ 0, & c = \infty \end{cases},$$

implying that the sequence (u_n) satisfies (ε_n) -local compactness condition if and only if $\lim_n \frac{\varepsilon_n}{\omega_n} = \infty$.

Remark 5.6. In both previous examples we can see that the crucial relation between the characteristic length of the sequence (ω_n) and the characteristic length of the condition (ε_n) is $\lim_n \frac{\varepsilon_n}{\omega_n} = \infty$. Thus, in terms of [24], the characteristic lengths of sequences should be *faster* than the characteristic lengths of the condition. One can notice that this is a stronger requirement than what is needed for the (ε_n) -oscillatory property (see [24, examples 1 and 2]).

5.2. Localisation principle. After completing all these preliminaries, we are ready to present the localisation principle for one-scale H-distributions.

Theorem 5.7. *Take $\Omega \subseteq \mathbb{R}^d$ open and $p \in (1, \infty)$. Let $\mathbf{u}_n \rightharpoonup 0$ in $L_{\text{loc}}^p(\Omega; \mathbb{C}^r)$ satisfy (5.1), where (ε_n) is a sequence of positive real numbers, $\mathbf{A}_n^\alpha \in C(\Omega; M_{q \times r}(\mathbb{C}))$, such that for any $\alpha \in \mathbb{N}_0^d$ the sequence $\mathbf{A}_n^\alpha \rightarrow \mathbf{A}^\alpha$ in the space $C(\Omega; M_{q \times r}(\mathbb{C}))$ (in other words, \mathbf{A}_n^α converges locally uniformly to \mathbf{A}^α), while (f_n) is a sequence of functions in $W_{\text{loc}}^{-m,p}(\Omega; \mathbb{C}^r)$ satisfying (ε_n) -local compactness condition (5.3). Moreover, let (v_n) be a bounded sequence in $L_{\text{loc}}^{p'}(\Omega; \mathbb{C}^r)$ and let $\omega_n \rightarrow 0^+$ be a sequence of positive reals such that $c := \lim_n \frac{\omega_n}{\varepsilon_n}$ exists (in $[0, \infty]$).*

Then any one-scale H-distribution $\nu_{K_{0,\infty}}^{(\omega_n)}$ associated to (sub)sequences (of) (\mathbf{u}_n) and (v_n) with characteristic length (ω_n) satisfies:

$$(5.4) \quad \mathbf{p}_c(\mathbf{x}, \boldsymbol{\xi}) \nu_{K_{0,\infty}} = \mathbf{0},$$

where, with respect to the value of c , we have

i) $c = 0$:

$$\mathbf{p}_0(\mathbf{x}, \boldsymbol{\xi}) = \sum_{|\alpha|=m} (2\pi i)^m \frac{\boldsymbol{\xi}^\alpha}{1 + |\boldsymbol{\xi}|^m} \mathbf{A}^\alpha(\mathbf{x}),$$

ii) $c \in (0, \infty)$:

$$\mathbf{p}_c(\mathbf{x}, \boldsymbol{\xi}) = \sum_{|\alpha| \leq m} \left(\frac{2\pi i}{c} \right)^{|\alpha|} \frac{\boldsymbol{\xi}^\alpha}{1 + |\boldsymbol{\xi}|^m} \mathbf{A}^\alpha(\mathbf{x}),$$

iii) $c = \infty$:

$$\mathbf{p}_\infty(\mathbf{x}, \boldsymbol{\xi}) = \frac{1}{1 + |\boldsymbol{\xi}|^m} \mathbf{A}^0(\mathbf{x}).$$

Proof. I. Let us first show that we can replace \mathbf{A}_n^α by \mathbf{A}^α in (5.1). It is sufficient to show that

$$\sum_{|\alpha| \leq m} \varepsilon_n^{|\alpha|} \partial_\alpha \left((\mathbf{A}_n^\alpha - \mathbf{A}^\alpha) \mathbf{u}_n \right)$$

satisfies the (ε_n) -local compactness condition (5.3), as then the new right hand side

$$\tilde{f}_n := f_n - \sum_{|\alpha| \leq m} \varepsilon_n^{|\alpha|} \partial_\alpha \left((\mathbf{A}_n^\alpha - \mathbf{A}^\alpha) \mathbf{u}_n \right)$$

still satisfies the same (ε_n) -local compactness condition.

Since $(\mathbf{A}_n^\alpha - \mathbf{A}^\alpha) \mathbf{u}_n$ strongly converges to 0 in $L_{\text{loc}}^p(\Omega; \mathbb{C}^r)$, the sequence of functions $\partial_\alpha((\mathbf{A}_n^\alpha - \mathbf{A}^\alpha) \mathbf{u}_n)$ strongly converges to 0 in $W_{\text{loc}}^{-|\alpha|,p}(\Omega; \mathbb{C}^r)$. Thus, the claim follows by Lemma 5.4.

For simplicity of notation, we shall continue to use f_n instead of \tilde{f}_n for denoting the right hand side.

II. In the next step we localise (5.1) by multiplying it by a test function $\varphi \in C_c^\infty(\Omega)$, and after applying the Leibniz rule (cf. [7, Lemma 8] and [27, Lemma 9] for details) we have

$$\sum_{|\alpha| \leq m} \sum_{0 \leq \beta \leq \alpha} (-1)^{|\beta|} \binom{\alpha}{\beta} \varepsilon_n^{|\alpha|} \partial_{\alpha-\beta} \left((\partial_\beta \varphi) \mathbf{A}^\alpha \mathbf{u}_n \right) = \varphi f_n.$$

Our aim is to show that the terms with $\beta \neq 0$ on the left hand side of this equality satisfy the (ε_n) -compactness condition (5.2), i.e. that we can insert them into the right hand side.

For given α and β the sequence $\partial_{\alpha-\beta}\left((\partial_\beta\varphi)\mathbf{A}^\alpha\mathbf{u}_n\right)$ is supported in a fixed compact ($\text{supp } \varphi$), hence by the Rellich compactness theorem for $\beta \neq 0$ it is strongly precompact in $W^{-|\alpha|,p}(\mathbb{R}^d; \mathbb{C}^r)$. Therefore, by Lemma 5.4 we get that $\varepsilon_n^{|\alpha|}\partial_{\alpha-\beta}\left((\partial_\beta\varphi)\mathbf{A}^\alpha\mathbf{u}_n\right)$ satisfies (5.2).

By the arbitrariness of α and β we get the claim, so the equality above can be rewritten in the form

$$(5.5) \quad \sum_{|\alpha| \leq m} \varepsilon_n^{|\alpha|} \partial_\alpha (\mathbf{A}^\alpha \varphi \mathbf{u}_n) = \tilde{f}_n,$$

where the sequence (\tilde{f}_n) satisfies (5.2).

III. Let us first assume that $\omega_n = \varepsilon_n$, i.e. $c = 1$, while the proof of the general case we postpone to the last step.

By applying $\mathcal{A}_{\frac{1}{1+\varepsilon_n|\xi|^m}}$ to (5.5) we get

$$\sum_{|\alpha| \leq m} \mathcal{A}_{(2\pi i)^{|\alpha|} \psi_n^{m,\alpha}} (\varphi \mathbf{A}^\alpha \mathbf{u}_n) \longrightarrow 0 \quad \text{in } L^p(\mathbb{R}^d; \mathbb{C}^r),$$

where $\psi^{m,\alpha}(\xi) = \frac{\xi^\alpha}{1+|\xi|^m}$ (this function is in $C^\infty(K_{0,\infty}(\mathbb{R}^d))$; see Corollary 2.6(iii)) and we denote $\psi_n^{m,\alpha} = \psi^{m,\alpha}(\varepsilon_n \cdot)$. Further on, for an arbitrary $\psi \in C^{d(\lfloor \frac{d}{2} \rfloor + 3)}(K_{0,\infty}(\mathbb{R}^d))$, we apply \mathcal{A}_{ψ_n} (here $\psi_n = \psi(\varepsilon_n \cdot)$) to the above sum and form a complex tensor product with $\varphi_1 v_n$, for an arbitrary $\varphi_1 \in C_c^\infty(\Omega)$. After using u_n^s, v_n^l and A_{ks}^α to denote components of $\mathbf{u}_n, \mathbf{v}_n$ and \mathbf{A}^α respectively, for the (k, l) component of the above sum on the limit we get

$$\begin{aligned} 0 &= \sum_{|\alpha| \leq m} \sum_{s=1}^d \lim_n \int_{\mathbb{R}^d} \mathcal{A}_{(2\pi i)^{|\alpha|} \psi_n^{m,\alpha}} (\varphi A_{ks}^\alpha u_n^s) \overline{\varphi_1 v_n^l} dx \\ &= \sum_{|\alpha| \leq m} \sum_{s=1}^d \left\langle \nu_{K_{0,\infty}}^{sl}, \varphi \bar{\varphi}_1 A_{ks}^\alpha \otimes (2\pi i)^{|\alpha|} \psi \psi^{m,\alpha} \right\rangle \\ &= \sum_{|\alpha| \leq m} \sum_{s=1}^d \left\langle (2\pi i)^{|\alpha|} \psi^{m,\alpha} A_{ks}^\alpha \nu_{K_{0,\infty}}^{sl}, \varphi \bar{\varphi}_1 \otimes \psi \right\rangle \\ &= \left\langle \sum_{|\alpha| \leq m} \frac{(2\pi i \xi)^\alpha}{1+|\xi|^m} [\mathbf{A}^\alpha \nu_{K_{0,\infty}}]_{kl}, \varphi \bar{\varphi}_1 \otimes \psi \right\rangle, \end{aligned}$$

where $\nu_{K_{0,\infty}}$ is the one-scale H-distribution with characteristic scale (ε_n) associated to the chosen subsequences of (\mathbf{u}_n) and (\mathbf{v}_n) .

As test functions φ, φ_1 and ψ are arbitrary, and tensor products are dense in the space $C_c^{0,d(\lfloor \frac{d}{2} \rfloor + 3)}(\Omega \times K_{0,\infty}(\mathbb{R}^d))$, we get the claim.

IV. Let us consider now the case of a general sequence $\omega_n \rightarrow 0^+$. The aim is to transform the equation to the form in which the characteristic length ε_n is replaced by ω_n and in which the right hand side satisfies the (ω_n) -local compactness condition. Then we can apply steps I–III in order to get the result.

If $c \in (0, \infty]$, we rewrite (5.1) in the form

$$\sum_{|\alpha| \leq m} \omega_n^{|\alpha|} \partial_\alpha (\mathbf{B}_n^\alpha \mathbf{u}_n) = f_n,$$

where $\mathbf{B}_n^\alpha := \left(\frac{\varepsilon_n}{\omega_n}\right)^{|\alpha|} \mathbf{A}_n^\alpha$. Since \mathbf{B}_n^α converges to $c^{-|\alpha|} \mathbf{A}^\alpha$ in $C(\Omega; M_{q \times r}(\mathbb{C}))$ and by Lemma 5.2(i) the sequence (\mathbf{f}_n) satisfies the (ω_n) -local compactness condition, we are in a position to apply steps I–III. Let us note that for $c = \infty$ non-trivial terms are only present for $\alpha = 0$.

For $c = 0$ we first multiply (5.1) by $\left(\frac{\omega_n}{\varepsilon_n}\right)^m$ and then rewrite it in the form

$$\sum_{|\alpha| \leq m} \omega_n^{|\alpha|} \partial_\alpha (\mathbf{C}_n^\alpha u_n) = \mathbf{g}_n,$$

where $\mathbf{C}_n^\alpha := \left(\frac{\omega_n}{\varepsilon_n}\right)^{m-|\alpha|} \mathbf{A}_n^\alpha$ and $\mathbf{g}_n := \left(\frac{\omega_n}{\varepsilon_n}\right)^m \mathbf{f}_n$. It is obvious that sequence \mathbf{C}_n^α converges in $C(\Omega; M_{q \times r}(\mathbb{C}))$ and the limit is $\mathbf{0}$ for $|\alpha| \leq m - 1$ and \mathbf{A}^α for $|\alpha| = m$. It remains to be shown that (\mathbf{g}_n) satisfies the (ω_n) -local compactness condition. Indeed, we have

$$\begin{aligned} \left(\frac{\omega_n}{\varepsilon_n}\right)^m \frac{1}{1 + |\omega_n \boldsymbol{\xi}|^m} &= \frac{\left(\frac{\omega_n}{\varepsilon_n}\right)^m + |\omega_n \boldsymbol{\xi}|^m}{1 + |\omega_n \boldsymbol{\xi}|^m} \frac{1}{1 + |\varepsilon_n \boldsymbol{\xi}|^m} \\ &= \left(1 + \frac{\left(\frac{\omega_n}{\varepsilon_n}\right)^m - 1}{1 + |\omega_n \boldsymbol{\xi}|^m}\right) \frac{1}{1 + |\varepsilon_n \boldsymbol{\xi}|^m}. \end{aligned}$$

Now we take into account the fact that (\mathbf{f}_n) satisfies the (ε_n) -local compactness condition (for which we use the second factor), while the first factor defines a bounded sequence of L^p Fourier multipliers, which can be shown following the same argument as it was done in the proof of Lemma 5.2. \square

- Remark 5.8.*
- i) The application of Theorem 5.7, together with Lemma 4.6, could be seen as an L^p variant of *compactness by compensation* (in literature also referred to as *compensated compactness*) suitable for problems with a characteristic length. In this context it is important to notice that we allow for variable coefficients of the corresponding partial differential equations, which need to be merely continuous.
 - ii) In this paper we chose to work with bilinear dual products, while in [7] sesquilinear dual products were used. Because of that there is a small difference in formulae (5.4) and [7, (4.10)] (when compared for $p = 2$): here we do not have the transpose of the one-scale H-distribution.
 - iii) The case $\varepsilon_n \rightarrow 0^+$ is of the utmost importance in the problems with characteristic scales, but let us briefly address some remarks concerning the case $0 < \varepsilon_0 \leq \varepsilon_n \leq \varepsilon_\infty < \infty$, which is the case $c = 0$ of Theorem 5.7. Since \mathbf{p}_0 is equal to zero on Σ_0 , our result (5.4) does not provide information about the distribution on the whole domain.

This problem can be solved by showing that the localisation principle (5.4) still holds if we replace symbol \mathbf{p}_0 by

$$\tilde{\mathbf{p}}_0(\mathbf{x}, \boldsymbol{\xi}) = \sum_{|\alpha|=m} (2\pi i)^m \frac{\boldsymbol{\xi}^\alpha}{|\boldsymbol{\xi}|^m} \mathbf{A}^\alpha(\mathbf{x}),$$

i.e. one needs to remove '1' in the denominator. In [7] that was done in the L^2 setting by applying a technical lemma (see Lemma 9 in the aforementioned reference). In the L^p framework this is a bit more demanding since one needs to work with the Fourier multiplier. The standard approach is to use Riesz potentials in this case, as it was done in [13, Theorem 4.1] for the first order differential equations. However, this approach requires to have a better integrability property of the sequence (v_n) .

Of course, this adjustment, i.e. the removal of '1', cannot be done (in general) when $c = 0$, but $\liminf_n \varepsilon_n = 0$.

- iv) The previous theorem shows that (ε_n) -local compactness of the right hand side is sufficient to ensure (5.4). For the case $p = 2$ it was proven in [7, Theorem 9] that it is also a necessary condition.

5.3. Applications. In this subsection we present a possible application of Theorem 5.7 in a simple example.

Let $\Omega \subseteq \mathbb{R}^2$ be open and let $p \in (1, \infty)$. Assume that $u_n \rightharpoonup 0$ in $L^p_{\text{loc}}(\Omega)$ and $v_n \rightharpoonup 0$ in $L^{p'}_{\text{loc}}(\Omega)$ satisfy

$$(5.6) \quad \begin{cases} u_n + \varepsilon_n \partial_{x_1}(a_1 u_n) = f_n \\ v_n + \varepsilon_n^\alpha \partial_{x_2}(a_2 v_n) = g_n, \end{cases}$$

where $\varepsilon_n \rightarrow 0^+$, $\alpha \in (0, 1]$, $f_n \in W_{\text{loc}}^{-1,p}(\Omega)$ and $g_n \in W_{\text{loc}}^{-1,p'}(\Omega)$ satisfy the (ε_n) -local compactness condition for $m = 1$ (f_n in L^p and g_n in $L^{p'}$), and $a_1, a_2 \in C(\Omega; \mathbb{R})$ such that $a_1, a_2 \neq 0$ everywhere.

Let μ be a one-scale H-distribution associated to (sub)sequences (of) (u_n) and (v_n) with characteristic length (ε_n) . For simplicity, here we do not relabel the subsequences, but one needs to be aware that all conclusions extracted from one-scale H-distributions are at the level of the chosen subsequences (unless the sequences are (ε_n) -pure). This is a common situation when studying weakly converging sequences.

After applying Theorem 5.7 to the first equality in (5.6) we get

$$\left(\frac{1}{1 + |\boldsymbol{\xi}|} + \frac{2\pi i a_1(\mathbf{x}) \xi_1}{1 + |\boldsymbol{\xi}|} \right) \mu = 0.$$

The symbol

$$p(\mathbf{x}, \boldsymbol{\xi}) := \frac{1}{1 + |\boldsymbol{\xi}|} + \frac{2\pi i a_1(\mathbf{x}) \xi_1}{1 + |\boldsymbol{\xi}|}$$

is equal to zero only when both functions $\boldsymbol{\xi} \mapsto \frac{1}{1 + |\boldsymbol{\xi}|}$ and $\boldsymbol{\xi} \mapsto \frac{a_1(\mathbf{x}) \xi_1}{1 + |\boldsymbol{\xi}|}$ are equal to zero, which occurs only for $(\mathbf{x}, \boldsymbol{\xi}) \in \Omega \times \{\infty^{(0,-1)}, \infty^{(0,1)}\}$. Since for any $\Phi \in C^{0,d}(\lfloor \frac{d}{2} \rfloor + 3)(\Omega \times K_{0,\infty}(\mathbb{R}^d))$ equal to zero on a neighbourhood of both points $\infty^{(0,-1)}$ and $\infty^{(0,1)}$ in $K_{0,\infty}(\mathbb{R}^d)$ we have $\frac{1}{p} \Phi \in C^{0,d}(\lfloor \frac{d}{2} \rfloor + 3)(\Omega \times K_{0,\infty}(\mathbb{R}^d))$, the above localisation principle implies

$$\langle \mu, \Phi \rangle = \langle \mu, p(\Phi/p) \rangle = \langle p\mu, \Phi/p \rangle = 0.$$

Therefore, the support of μ is localised within the set $\Omega \times \{\infty^{(0,-1)}, \infty^{(0,1)}\}$.

Let us now use the second equality in (5.6). A direct application of Theorem 5.7 requires from us to work with the one-scale H-distribution associated to (sub)sequences (of) (v_n) and (u_n) (the opposite order of sequences than it was above) with characteristic length (ε_n) . However, by Lemma 4.3 this one-scale H-distribution is equal to $\bar{\mu}$. Furthermore, depending on the value of α , we have two possible cases. Let us consider only the case $\alpha \in (0, 1)$ (the analysis for the remaining case $\alpha = 1$ is completely analogous). Thus, we have $\frac{2\pi i a_2(\mathbf{x}) \xi_2}{1 + |\boldsymbol{\xi}|} \bar{\mu} = 0$, implying

$$\frac{a_2(\mathbf{x}) \xi_2}{1 + |\boldsymbol{\xi}|} \mu = 0.$$

Since the function $(\mathbf{x}, \boldsymbol{\xi}) \mapsto \frac{a_2(\mathbf{x}) \xi_2}{1 + |\boldsymbol{\xi}|} \in C^{0,\infty}(\Omega \times K_{0,\infty}(\mathbb{R}^d))$ has no zeros in a neighbourhood of the set $\Omega \times \{\infty^{(0,-1)}, \infty^{(0,1)}\}$, as in the above argument we can conclude that $\text{supp } \mu \cap (\Omega \times \{\infty^{(0,-1)}, \infty^{(0,1)}\}) = \emptyset$. Therefore, the overall conclusion is $\mu = 0$.

By the definition of the one-scale H -distribution (see Remark 4.7) this means that there exist subsequences $(u_{n'})$ and $(v_{n'})$ such that $u_{n'}\bar{v}_{n'} \xrightarrow{*} 0$ in the sense of (unbounded) Radon measures.

Let us close this subsection by presenting a concrete choice for data in (5.6).

Example 5.9. Let $\Omega = \mathbb{R}^2$ and let $p \in (1, \infty)$. For $u_1, u_2 \in L^p(\Omega)$ and $v_1, v_2 \in L^{p'}(\Omega)$ we define

$$\begin{aligned} u_n(x_1, x_2) &:= u_1(x_1)e^{2\pi i n x_1} + n^{2/p}u_2(n^2x_2), \\ v_n(x_1, x_2) &:= n^{2/p'}v_1(n^2x_1) + v_2(x_2)e^{2\pi i n x_2}. \end{aligned}$$

The sequence of functions

$$\begin{aligned} f_n(x_1, x_2) &:= u_n(x_1, x_2) - \frac{1}{n}\partial_{x_1}u_n(x_1, x_2) \\ &= u_1(x_1)e^{2\pi i n x_1} + n^{2/p}u_2(n^2x_2) - \frac{1}{n}u_1'(x_1)e^{2\pi i n x_1} - u_1(x_1)e^{2\pi i n x_1} \\ &= n^{2/p}u_2(n^2x_2) - \frac{1}{n}u_1'(x_1)e^{2\pi i n x_1} \end{aligned}$$

satisfies the $(1/n)$ -local compactness condition in $L^p(\mathbb{R}^d)$ (with $m = 1$). Indeed, for the first term in the last equality we apply Example 5.5(i), while for the second we use Lemma 5.4, since $(\frac{1}{n}u_1'(x_1)e^{2\pi i n x_1})$ converges strongly to zero in $W^{-1,p}(\mathbb{R})$.

Analogously,

$$\begin{aligned} g_n(x_1, x_2) &:= v_n(x_1, x_2) - \frac{1}{n}\partial_{x_2}v_n(x_1, x_2) \\ &= n^{2/p'}v_1(n^2x_1) - \frac{1}{n}v_2'(x_2)e^{2\pi i n x_2} \end{aligned}$$

satisfies the $(1/n)$ -local compactness condition in $L^{p'}(\mathbb{R}^d)$ (again with $m = 1$).

Thus, sequences (u_n) and (v_n) satisfy (5.6) with $\varepsilon_n = \frac{1}{n}$, $\alpha = 1$ and $a_1 = a_2 = -1$, so that $u_n\bar{v}_n \xrightarrow{*} 0$. This can easily be checked by a direct inspection of sequences.

In this example the whole sequence converges since sequences (u_n) and (v_n) are $(1/n)$ -pure (see subsections 4.2 and 4.3).

6. ACKNOWLEDGEMENTS

The authors wish to thank Eduard Nigsch for numerous helpful discussions.

This work is supported in part by the Croatian Science Foundation under the project IP-2018-01-2449 (MiTPDE) and by the Croatian-Austrian bilateral project *Anisotropic distributions and H -distributions*.
