Abstract

We initiate a study of supervised learning from many independent sequences ("trajectories") of non-independent covariates, reflecting tasks in sequence modeling, control, and reinforcement learning. Conceptually, our multi-trajectory setup sits between two traditional settings in statistical learning theory: learning from independent examples and learning from a single auto-correlated sequence. Our conditions for efficient learning generalize the former setting—trajectories must be non-degenerate in ways that extend standard requirements for independent examples. They do not require that trajectories be ergodic, long, nor strictly stable.

For linear least-squares regression, given $n$-dimensional examples produced by $m$ trajectories, each of length $T$, we observe a notable change in statistical efficiency as the number of trajectories increases from a few (namely $m \lesssim n$) to many (namely $m \gtrsim n$). Specifically, we establish that the worst-case error rate this problem is $\Theta(n/mT)$ whenever $m \gtrsim n$. Meanwhile, when $m \lesssim n$, we establish a (sharp) lower bound of $\Omega(n^2/m^2T)$ on the worst-case error rate, realized by a simple, marginally unstable linear dynamical system. A key upshot is that, in domains where trajectories regularly reset, the error rate eventually behaves as if all of the examples were independent altogether, drawn from their marginals. As a corollary of our analysis, we also improve guarantees for the linear system identification problem.

1 Introduction

Statistical learning theory aims to characterize the worst-case efficiency of learning from example data. Its most common setup assumes that examples are independently and identically distributed ($iid$) draws from an underlying data distribution, but various branches of theory—not to mention deployed applications of machine learning—consume non-independent data as well. An especially fruitful setting, and the focus of this paper, is in learning from sequential data, where examples are generated by some ordered stochastic process that renders them possibly correlated. Naturally, sequential processes describe application domains spanning engineering and the sciences, such as robotics (Nguyen-Tuong and Peters, 2011), data center cooling (e.g. Lazic et al. (2018)), language (e.g. Sutskever et al. (2014); Belanger and Kakade (2015)), neuroscience (e.g. Linderman et al. (2017); Glaser et al. (2020)), and economic forecasting (McDonald et al., 2017). Learning over sequential data can also capture some formulations of imitation learning (Osa et al., 2018) and reinforcement learning (Chen et al., 2021; Janner et al., 2021).
In supervised learning, one learns to predict output *labels* from input *covariates*, given example pairings of the two. Formal treatments of learning from sequential data typically concern a single inter-dependent chain of covariates. Where these treatments vary is in their assumptions about the underlying process that generates the covariate chain. For instance, some assume that the process is auto-regressive (e.g. Lai and Wei (1983); Goldenshluger and Zeevi (2001); González and Rojas (2020)) or ergodic (e.g. Yu (1994); Duchi et al. (2012)). Others assume that it is a linear dynamical system (e.g. Simchowitz et al. (2018); Faradonbeh et al. (2018); Sarkar and Rakhlin (2019)).

In this paper, we examine what happens when we learn from many independent chains rather than one, as one does anyway in many applications (e.g. Pomerleau (1989); Khansari-Zadeh and Billard (2011); Brants et al. (2007); Józefowicz et al. (2016)). Figure 1 depicts the data dependence structure of our setup in comparison with its two natural counterparts. Learning from a dataset of many short (constant length) chains ought to be similar to independent learning, even if each chain is highly intra-dependent. On the other hand, for any non-trivial chain length, intuition suggests that the error can degrade relative to the total sample size in the worst case, since a greater proportion of the data may contain correlations. Lower bounds even show that, when one sees only a single chain, this degradation is outright necessary in the worst case (Bresler et al., 2020). Do we see any such effect with many chains?

We study this question by sharply characterizing worst-case error rates of a fundamental task—linear regression—imposed over a general sequential data model. Our findings reveal a remarkable phenomenon: after seeing sufficiently many chains ($m$) relative to the example dimension $n$, no matter the chain length $T$, the error rate matches that of learning from the same total number $mT$ of independent examples, drawn from their respective marginal distributions.
In our data model, each chain, called a trajectory, comprises a sequence of covariates \( \{x_t\} \) generated from a stochastic process. Each covariate is accompanied by a noisy linear response \( y_t \) as its label. A training set generated from a stochastic process. Each covariate is accompanied by a noisy linear response \( y \) dynamical system (LDS). Specifically, fixing matrices \( A \) of our risk upper bounds are guarantees for the ordinary least-squares estimator in particular. Fixing matrices \( A \), \( B \), and \( W \) such a training set, an estimator produces a hypothesis that predicts the label of any covariate. It is a target of length \( T \), possibly unequal to \( T \)—a notion of risk defined naturally over a trajectory. All of our risk upper bounds are guarantees for the ordinary least-squares estimator in particular.

A concrete, recurring example in this paper takes the covariate-generating process to be a linear dynamical system (LDS). Specifically, fixing matrices \( A \in \mathbb{R}^{n \times n} \), \( B \in \mathbb{R}^{n \times d} \), and \( W \in \mathbb{R}^{p \times n} \), a single trajectory \( \{(x_t, y_t)\}_{t \geq 1} \) is generated as follows. Let \( x_0 = 0 \), and for \( t \geq 1 \):

\[
\begin{align*}
    x_t &= Ax_{t-1} + Bw_t, & \text{(linear dynamics)} \\
    y_t &= W^* x_t + \xi_t, & \text{(linear regression)}
\end{align*}
\]

where the \( \{w_t\}_{t \geq 1} \) are iid centered isotropic Gaussian draws and \( \{\xi_t\}_{t \geq 1} \) is a sub-Gaussian martingale difference sequence (with respect to past covariates \( \{x_k\}_{k=1}^t \) and noise variables \( \{\xi_k\}_{k=1}^{t-1} \)). Incidentally, combining linear dynamical systems with linear regression captures the basic problem of linear system identification (as in Simchowitz et al. (2018)) as a special case.

In other instantiations of learning from trajectories, the covariates \( \{x_t\} \) may be generated by a different process; what remains common is the superimposed regression task set up by the ground truth \( W^* \) and the noise \( \{\xi_t\} \). The key condition that we will introduce, which renders a covariate process amenable to regression, is that it satisfies a trajectory small-ball condition (Definition 4.1). Section 4.1 shows that LDS-generated data conforms to the trajectory small-ball condition in particular, as do many other distributions.

Our main results (Sections 4 and 5) sharply characterize worst-case rates of learning from trajectory data as a function of the training trajectory count \( m \), the training trajectory length \( T \), the evaluation length \( T' \), the covariate and response dimensions \( n \) and \( p \), and scale parameters of noise in the data model (such as the variance of the noise \( \{\xi_t\} \)). Restricting only to terms of covariate dimension \( n \), training set size \( m \) and \( T \), and evaluation length \( T' \), our bounds imply the following summary statement:

**Theorem 1.1** (informal; error rate with many small-ball trajectories, \( T' \leq T \)). If \( m \geq n \), \( T' \leq T \), and covariate trajectories are drawn from a trajectory small-ball distribution, then the worst-case excess prediction risk (over evaluation horizon \( T' \)) for linear regression from \( m \) many trajectories of \( n \)-dimensional covariates, each of length \( T \), is \( \Theta(n/(mT)) \).

In drawing comparisons to learning from independent examples, it makes sense to consider training and evaluations lengths \( T \) and \( T' \) equal (cf. Section 3), rendering Theorem 1.1 applicable. The theorem thus echoes our main point above: the same rate of \( \Theta(n/(mT)) \) describes regression on \( mT \) independent examples (details on this point are expanded in Section 3.3).

Further structural assumptions are needed (cf. Section 3.3) in order to cover the remaining range of problem dimensions, namely few trajectories \( m \lesssim n \) or extended evaluations \( (T' > T) \), and to that end we return to linear dynamical systems as a focus. Our remaining risk upper bounds, targeting learning under linear dynamics, require that the dynamics matrix \( A \) be marginally unstable (meaning that its spectral radius \( \rho(A) \) is at most one) and diagonalizable. When trajectories are longer at test time than during training (i.e., \( T' > T \)), marginal instability is practically necessary, otherwise the risk can scale exponentially in \( T' - T \). The assumption otherwise still allows for
unstable—and therefore non-ergodic—systems at \( \rho(A) = 1 \). For simplicity, we also require that the control matrix \( B \) have full row rank. Our bounds then imply the following summary statement about regression when the number of trajectories is limited:

**Theorem 1.2** (informal; error rate with few LDS trajectories). If \( m \lesssim n \), \( mT \gtrsim n \), and covariate trajectories are drawn from a linear dynamical system whose dynamics \( A \) are marginally unstable and diagonalizable, then the worst-case excess prediction risk (over evaluation horizon \( T' \)) for linear regression from \( m \) many trajectories of \( n \)-dimensional covariates, each of length \( T \), is \( \tilde{\Theta}(n/(mT) \cdot \max\{nT'/(mT), 1\}) \).

If the evaluation horizon \( T' \) is a constant, the rate in Theorem 1.2 recovers that of Theorem 1.1, up to log factors and extra assumptions. To draw further comparison, suppose that the training and evaluation horizons are equal, i.e., that \( T' = T \). On the face of it, the rate in Theorem 1.2 is evidently weaker than that of Theorem 1.1, by up to a factor of the covariate dimension \( n \). But the varying premises—of many vs. few trajectories—necessarily constrain the risk definitions to differ. Under a fixed data budget \( N := mT = mT' \), fewer trajectories \( m \) imply a longer horizon \( T' \) over which the risk is evaluated. Intuitively, a longer evaluation horizon makes for a different problem, and renders the rate comparison invalid.

A more sound comparison across regimes is possible by first normalizing the notion of performance within a problem instance. To this end, we can consider the worst-case risk of learning from trajectories relative to that of learning from independent examples in the same regime. Constructing the latter baseline is somewhat subtle (cf. Section 3.2). To decorrelate the problem of learning from trajectories while maintaining its temporal structure otherwise, we can imagine drawing from its marginal distributions independently at each time step. The resulting dataset is independent, but not identically distributed. Although the rates for the sequential and decorrelated regression problems are—as already highlighted—remarkably the same under many trajectories, the few-trajectory rate in Theorem 1.2 is indeed weaker than the \( \Theta(n/(mT)) \) rate that we prove for its decorrelated baseline (cf. Theorem 4.8).

Since the more general Theorem 1.1 already describes what happens under many trajectories \( (m \gtrsim n) \) and a strict evaluation horizon \( (T' \leq T) \), what remains is a somewhat niche regime: many trajectories and an extended evaluation horizon \( T' > T \). For completeness, our bounds supply the following summary statement:

**Theorem 1.3** (informal; error rate with many LDS trajectories). If \( m \gtrsim n \) and covariate trajectories are drawn from a linear dynamical system whose dynamics \( A \) are marginally unstable and diagonalizable, then the worst-case excess prediction risk (over evaluation horizon \( T' \)) for linear regression from \( m \) many trajectories of \( n \)-dimensional covariates, each of length \( T \), is \( \Theta(n/(mT) \cdot \max\{T'/T, 1\}) \).

Using the tools of our analysis, we also develop upper bounds for parameter error instead of prediction risk, which inform recovery of the ground truth \( W_\star \) and (by reduction) of the dynamics matrix \( A \) in LDS. The latter captures the linear system identification problem. Our upper bounds improve on its worst-case guarantees by a factor of \( 1/T \) where applicable, and extend the parameter ranges in which guarantees hold at all.
2 Related work

Linear regression is a basic and well-studied problem. The two treatments most closely related to our work are Hsu et al. (2014) and Mourtada (2019), who develop sharp finite-sample characterizations of the risk of random design linear regression (i.e., from iid examples). Discussion and references therein cover the broader problem over its long history.

A common approach to studying dependent covariates is to assume that the data-generating process is ergodic (see e.g. Yu (1994); Meir (2000); Mohri and Rostamizadeh (2008); Steinwart and Christmann (2009); Mohri and Rostamizadeh (2010); Duchi et al. (2012); Kuznetsov and Mohri (2017); McDonald et al. (2017); Shalizi (2021) and references therein). The key phenomenon at play is that $N$ correlated examples are statistically similar to $N/\tau_{\text{mix}}$ independent examples, where $\tau_{\text{mix}}$ is the process mixing-time. Relying on this idea, generalization bounds informing independent data can typically be ported to the ergodic setting, where the effective sample size is simply “deflated” by a factor of $\tau_{\text{mix}}$. Since mixing-based bounds become vacuous as $\tau_{\text{mix}} \to \infty$, they do not present an effective strategy for studying dynamics that do not mix. A critical instance of this arises in linear dynamical systems: in LDS, the ergodicity condition amounts to stability of the dynamics matrix $A$ (i.e., $\rho(A) < 1$), where $\tau_{\text{mix}} \to \infty$ as $\rho(A) \to 1$ (e.g. Meyn and Tweedie, 1993, Thm. 17.6.2). Marginally unstable systems, in which $\rho(A) = 1$, are thus not captured.

Recently, Bresler et al. (2020) showed that for least-squares regression on Markovian data, risk bounds that are deflated by a factor of the mixing time $\tau_{\text{mix}}$ are actually unavoidable in an information-theoretic sense, under an agnostic data model. They also show that an initial burn-in time proportional to $\tau_{\text{mix}}$ is necessary, under any data model. Their work hence motivates studying more specific sequential learning configurations.

**System identification.** A special case of our LDS-specific data model captures linear system identification with full state observation: the task of recovering the dynamical system parameters $A$ from observations of trajectories. While classic results are asymptotic in nature (see e.g. Lai and Wei (1982, 1983); Ljung (1998)), recent work gives finite-sample guarantees for recovery of linear systems with fully observed states (Simchowitz et al., 2018; Dean et al., 2020; Jedra and Proutiere, 2020; Faradonbeh et al., 2018; Sarkar and Rakhlin, 2019; Jedra and Proutiere, 2019; Tsiamis and Pappas, 2021), and also partially observed states (Oymak and Ozay, 2019; Simchowitz et al., 2019; Tsiamis and Pappas, 2019; Sarkar et al., 2021; Zheng and Li, 2021). The proof of our upper bounds builds on the “small-ball” arguments from Simchowitz et al. (2018) (that, in turn, extend Mendelson (2015); Koltchinskii and Mendelson (2015)), which do not require ergodicity.

To the best of our knowledge, our results are the first to quantify the trade-offs between few long trajectories and many short trajectories. Nearly all finite-sample guarantees for linear system identification consider a single trajectory, with a few notable exceptions. Dean et al. (2020) allow for $m \geq 1$ trajectories with fully observed states and make no assumptions on the dynamics matrix $A$. However, their analysis discards all but the last state transition within a trajectory, reducing to iid learning over only $m$ examples. Zheng and Li (2021); Xin et al. (2022) study the recovery of Markov parameters from partially observed states over many trajectories. However, their error bounds do not decrease with longer training horizons $T$, since the number of Markov parameters one must recover scales with the trajectory length.

Furthermore, our LDS setup (Section 3.4) decouples the covariate dynamics model $A$ from the observation model $W_*$, and our risk definition additionally allows for an arbitrary evaluation horizon.
The real eigenvalues of a Hermitian matrix $M \in \mathbb{C}^{k \times k}$ are $\lambda_{\text{max}}(M) = \lambda_1(M) \geq \ldots \geq \lambda_k(M) = \lambda_{\text{min}}(M)$. For a square matrix $M \in \mathbb{C}^{k \times k}$, $M^*$ denotes its conjugate transpose, and $\rho(M)$ denotes its spectral radius: $\rho(M) = \max\{||\lambda|| \mid \lambda \text{ is an eigenvalue of } M\}$. The space of $n \times n$ real-valued symmetric positive semidefinite (resp. positive definite) matrices is denoted $\text{Sym}_n$ (resp. $\text{Sym}_n^+$). The non-negative (resp. positive) orthant in $\mathbb{R}^n$ is denoted as $\mathbb{R}^n_+$ (resp. $\mathbb{R}^n_+$), and $\mathbb{S}^{n-1}$ denotes the unit sphere in $\mathbb{R}^n$. Finally, the set of positive integers is denoted by $\mathbb{N}_+$. 

3 Problem formulation

**Notation.** The real eigenvalues of a Hermitian matrix $M \in \mathbb{C}^{k \times k}$ are $\lambda_{\text{max}}(M) = \lambda_1(M) \geq \ldots \geq \lambda_k(M) = \lambda_{\text{min}}(M)$. For a square matrix $M \in \mathbb{C}^{k \times k}$, $M^*$ denotes its conjugate transpose, and $\rho(M)$ denotes its spectral radius: $\rho(M) = \max\{||\lambda|| \mid \lambda \text{ is an eigenvalue of } M\}$. The space of $n \times n$ real-valued symmetric positive semidefinite (resp. positive definite) matrices is denoted $\text{Sym}_n$ (resp. $\text{Sym}_n^+$). The non-negative (resp. positive) orthant in $\mathbb{R}^n$ is denoted as $\mathbb{R}^n_+$ (resp. $\mathbb{R}^n_+$), and $\mathbb{S}^{n-1}$ denotes the unit sphere in $\mathbb{R}^n$. Finally, the set of positive integers is denoted by $\mathbb{N}_+$.

3.1 Linear regression from sequences

**Regression model.** A covariate sequence is an indexed set $\{x_t\}_{t \geq 1} \subset \mathbb{R}^n$. Any distribution $P_x$ over covariate sequences is assumed to have bounded second moments, i.e., that $E[x_t x_t^T]$ exists and is finite for all $t \geq 1$. Also for such a distribution $P_x$, let $P_x[P_x]$ be a distribution over observation noise sequences $\{\xi_t\}_{t \geq 1} \subset \mathbb{R}^p$. Denoting by $\{F_t\}_{t \geq 0}$ the filtration with $F_t = \sigma(\{x_k\}_{k=1}^{t-1}, \{\xi_k\}_{k=1}^{t-1})$, we assume that $\{\xi_t\}_{t \geq 1}$ is a $\sigma$-sub-Gaussian martingale difference sequence (MDS), i.e., for $t \geq 1$: 

$$E[\langle v, \xi_t \rangle \mid F_{t-1}] = 0, \ E[\exp(\lambda \langle v, \xi_t \rangle) \mid F_{t-1}] \leq \exp(\lambda^2 ||v||^2_2 \sigma_\xi^2 / 2) \text{ a.s.} \forall \lambda \in \mathbb{R}, v \in \mathbb{R}^p.$$ 

Given a ground truth model $W_* \in \mathbb{R}^{p \times n}$, define the observations (a.k.a. “responses” or “labels”):

$$y_t = W_* x_t + \xi_t, \quad t \geq 1. \quad (3.1)$$

Denote by $P_{x,y}^{W_*}[P_x, P_\xi]$ the joint distribution over covariates and their observations $\{(x_t, y_t)\}_{t \geq 1}$.

**Regression task.** Fix a ground truth model $W_* \in \mathbb{R}^{p \times n}$, a covariate distribution $P_x$, an observation noise model $P_\xi$, a training horizon $T$, and a test horizon $T'$. Draw $m$ independent sequences $\{(x_t^{(i)}, y_t^{(i)})\}_{i \in [m], t \geq 1}$ from $P_{x,y}^{W_*}[P_x, P_\xi]$, and call their length-$T$ prefixes $\{(x_t^{(i)}, y_t^{(i)})\}_{i = 1, t = 1}^{m, T}$ the training examples. From these examples, the regression task is to find a hypothesis $f_{m,T} : \mathbb{R}^n \to \mathbb{R}^p$ that matches ground truth predictions $f_{W_*}(x) := W_* x$ in expectation over unseen trajectories of length $T'$. The risk over an arbitrary evaluation horizon is harder to control than parameter error, which corresponds to an evaluation length of one. This is because the larger signal-to-noise ratio accrued by a less stable system magnifies the prediction error over the entire evaluation horizon. Although the observation model that we consider is mentioned in Simchowitz et al. (2018), the general setup with matching upper and lower bounds are all, to the best of our knowledge, new contributions.

A complementary line of work studies the problem of online sequence prediction in a no-regret framework, where the baseline expert class comprises of trajectories generated by a linear dynamical system (Hazan et al., 2017, 2018; Ghai et al., 2020). These results also allow for marginally unstable systems but are otherwise not directly comparable. Other efforts look beyond linear systems to identifying various non-linear classes, such as exponentially stable non-linear systems (Sattar and Oymak, 2020; Foster et al., 2020) and marginally unstable non-linear systems (Jain et al., 2021). These results again learn from a single trajectory. We believe that elements of our analysis can be ported over to offer many-trajectory bounds for these particular classes of non-linear systems.
\(\begin{align*} &\text{Specifically, the excess risk of a hypothesis } \hat{f} \text{ is:} \\
&L(\hat{f}; T', P_x) := \mathbb{E}_{P_x} \left[ \frac{1}{T'} \sum_{t=1}^{T'} \| \hat{f}(x_t) - f_{W_\ast}(x_t) \|_2^2 \right]. \quad (3.2) \\
\end{align*}\)

We say that the evaluation horizon \(T'\) is strict if \(T' \leq T\) and extended if \(T' > T\). When the hypothesis class is linear, meaning the hypotheses \(\hat{f}\) are of the form \(\hat{f}(x) = \hat{W}x\) with \(\hat{W} \in \mathbb{R}^{p \times n}\), the risk expression (3.2) simplifies as follows. For a positive definite matrix \(\Sigma \in \mathbb{P}\), distribution over labeled trajectories \(\Sigma\) in other words, provided the scale of the covariances \(\Sigma_t\) that measures the performance of a hypothesis at \(T'\) and other problem parameters such as \(m, T\) and other problem parameters such as \(n, p, \sigma_{\xi}\), and \(T'\). Recall that \(P_{x, y}\) denotes the distribution over labeled trajectories \(\{(x_t, y_t)\}_{t \geq 1}\). For a collection of covariate sequence distributions \(P_x\), the minimax risk over instance consistent with \(P_x\) is:

\(\begin{align*} &\text{Minimax risk. To compare the hardness of learning across problem classes (i.e., families of covariate distributions } P_x), \text{ we measure the minimax rate of the risk } L\text{—i.e., the behavior of the best estimator’s worst-case risk over valid problem instances—} \text{as a function of the amount of training data } m, T \text{ and other problem parameters such as } n, p, \sigma_{\xi}, \text{ and } T'. \text{ Recall that } P_{x, y}\text{ denotes the distribution over labeled trajectories } \{(x_t, y_t)\}_{t \geq 1}. \text{ For a collection of covariate sequence distributions } P_x, \text{ the minimax risk over instance consistent with } P_x \text{ is:} \\
&\mathbb{R}(m, T, T'; P_x) := \inf_{\text{Alg}} \sup_{P_{x, y}} \sup_{P_{x, y}} \mathbb{E}_{(x_{t,i}, y_{t,i})_{i=1}^{m,T}} \left[ L \left( \text{Alg}((x_{t,i}, y_{t,i})_{i=1}^{m,T}); T', P_x) \right) \right], \quad (3.5) \\
\end{align*}\)

where the infimum ranges over estimators \(\text{Alg} : (\mathbb{R}^n \times \mathbb{R}^p)^{mT} \to (\mathbb{R}^n \to \mathbb{R}^p)\) that map training samples to hypotheses, the supremum over \(W_\ast\) is over all \(p \times n\) ground truth models, and the supremum over \(P_{\xi}\) is over all \(\sigma_{\xi}\)-sub-Gaussian MDS processes determining the observation noise.
The ordinary least-squares estimator. Much like its classical role in iid learning, the ordinary least-squares (OLS) estimator will be key to bounding the minimax risk (3.5) from above. We define the OLS estimator to be the linear hypothesis $\hat{W}_{m,T} \in \mathbb{R}^{p \times n}$ that satisfies:

$$\hat{W}_{m,T} = \arg\min_{W \in \mathbb{R}^{p \times n}} \sum_{i=1}^{m} \sum_{t=1}^{T} \|W x_{t}^{(i)} - y_{t}^{(i)}\|_2^2. \quad (3.6)$$

For $i = 1, \ldots, m$, let $X_{m,T}^{(i)} \in \mathbb{R}^{T \times n}$ be the data matrix for the $i$-th trajectory (i.e., the $t$-th row of $X_{m,T}^{(i)}$ is $x_{t}^{(i)}$ for $t = 1, \ldots, T$). Define $Y_{m,T}^{(i)} \in \mathbb{R}^{T \times p}$ and $\Xi_{m,T}^{(i)} \in \mathbb{R}^{T \times p}$ analogously. Put $X_{m,T} \in \mathbb{R}^{mT \times n}$ as the vertical concatenation of $X_{m,T}^{(1)}, \ldots, X_{m,T}^{(m)}$, and similarly for $Y_{m,T} \in \mathbb{R}^{mT \times p}$ and $\Xi_{m,T} \in \mathbb{R}^{mT \times p}$. Whenever $X_{m,T}$ has full column rank, then we can write $\hat{W}_{m,T}$ as:

$$\hat{W}_{m,T} = Y_{m,T}^T X_{m,T}(X_{m,T}^T X_{m,T})^{-1}. \quad (3.7)$$

### 3.2 Problem classes

We formalize linear regression from sequential data generally as follows:

**Problem 3.1 (Seq-LS).** Assume a covariate sequence distribution $P_x$ in the linear regression model (3.1). Fix an evaluation horizon $T'$. On input $m$ labeled trajectories of length $T$ drawn from this model, in the form of examples $\{(x_{t}^{(i)}, y_{t}^{(i)})^{m,T}_{i=1,t=1}\}$, output a hypothesis $\hat{f}_{m,T}$ that minimizes excess risk $L(\hat{f}_{m,T}; T', P_x)$.

Our topmost goal is to study the effect of learning from sequentially dependent covariates in comparison with learning in the classical iid setup. Linear regression is well understood in the latter setting. Focusing on well-specified linear regression further simplifies our presentation, allowing us to isolate the effects of what interests us most—dependent covariates. Generalizing the supervision aspect of Seq-LS (say, to unrealizable and non-parametric regression, or to classification) is left to future work. We return to discuss this in Section 7.

To study how dependent data affects learning, we need to establish an “independent data” baseline. The natural comparison point for Seq-LS is to remove all correlations across time. Namely, instead of drawing covariates sequentially from the distribution $P_x$, consider learning separately from the marginals of $P_x$ at each time step. The resulting decorrelated distribution generates independent examples, but typically not iid ones. We formalize linear regression from independent data generally as follows:

**Problem 3.2 (Ind-Seq-LS).** Fix a sequence of distributions $\{P_{x,t}\}_{t \geq 1}$. Consider their product over time $\otimes_{t \geq 1} P_{x,t}$ as the covariate sequence distribution in the linear regression model (3.1). Fix an evaluation horizon $T'$. On input $m$ labeled trajectories of length $T$ drawn from this model, in the form of examples $\{(x_{t}^{(i)}, y_{t}^{(i)})^{m,T}_{i=1,t=1}\}$, output a hypothesis $\hat{f}_{m,T}$ that minimizes $L(\hat{f}_{m,T}; T', \otimes_{t \geq 1} P_{x,t})$.

This Ind-Seq-LS problem generalizes the canonical iid learning setup slightly. Existing theory can still characterize its minimax risk, provided the covariances of the distributions $\{P_{x,t}\}$ are roughly equal in scale across time $t$. However, this equal-scale requirement rules out the marginals of interesting applications, such as dynamical systems that are not stable or ergodic. We therefore extend, in later sections, characterizations of the regression risk to handle covariances that can scale polynomially across time instead.
3.3 Problem separations

To set up a baseline for a Seq-LS problem, we will specifically instantiate Ind-Seq-LS over its marginals. Namely, for a sequence distribution \( P_x \) over \( \{x_t\}_{t \geq 1} \), let \( \mu_t[P_x] \) be the marginal distribution of \( x_t \) at time \( t \geq 1 \), and consider Ind-Seq-LS with covariates drawn from the sequence \( \{\mu_t[P_x]\}_{t \geq 1} \). This decorrelated baseline is a hypothetical benchmark: in a practical context, collecting independent marginal data, when nature only supplies its dependent form, can be expensive or infeasible. However, we can expect that having such data on hand would make learning easier, with risk rates that resemble iid learning. In what follows, we outline scenarios where a sequential learning problem and its decorrelated baseline coincide in difficulty, and others in which they diverge. We then outline the possible assumptions that would allow us to always relate the two.

**The iid special case.** When \( T = T' = 1 \), the example trajectories \( \{x_1^{(i)}\}_{i=1}^m \) are trivially a set of iid covariates. The problems Seq-LS and Ind-Seq-LS thus coincide, and reduce to the well-specified random design linear regression problem over \( m \) iid covariates. It is well-known that under iid data, and mild regularity conditions, the minimax risk scales as \( \sigma^2 \xi pn/m \), and is achieved by the OLS estimator (Hsu et al., 2014; Mourtada, 2019; Wainwright, 2019).

**Extending the horizon.** Considering nontrivial horizons \( T = T' > 1 \), both Seq-LS and its corresponding Ind-Seq-LS baseline become more involved, but for different reasons.

The Ind-Seq-LS problem, as we show in Section 5, is not generally learnable with polynomially many examples. Specifically, the minimax rate scales exponentially in the dimension \( n \) provided the trajectory count \( m \) is constant. To address this, we will require that the covariances of its constituent distributions \( \{P_{x,t}\} \) grow at most polynomially with time \( t \). Under this constraint, the problem’s minimax risk again scales as the iid-like rate \( \sigma^2 pn/(mT) \) times, at most, a factor determined exponentially by the covariance growth.

The Seq-LS problem inherits the same growth limitation. Even then, it is still not generally learnable without further assumptions on the dependence structure of covariates: the minimax risk is otherwise bounded away from zero as the horizon \( T \) tends to infinity, provided the trajectory count \( m \) is constant. To realize this, consider \( x_1 \sim N(0, I_n) \) and \( x_t = x_{t-1} \) for \( t \geq 2 \), a sequence of identical covariates whose marginals are all independent Gaussians. The resulting dataset presents an underdetermined regression problem if \( m < n \). In essence, its covariates lack sufficient “excitation” across time. To rein Seq-LS back in to the realm of learnability, one must:

(a) make further modeling assumptions about covariates, or

(b) introduce excitation via independent resets.

For (a), as detailed in Section 2, the most common modeling assumption considers sequences that mix rapidly to a stationary distribution. Another avenue—recently active in the literature, and sometimes overlapping with the mixing approach—considers sequences generated by linear dynamical systems. Among these two, mixing implies risk bounds that tend to zero with \( T \), but only hold in the worst case after a burn-in time that scales proportionally to the mixing time (Bresler et al., 2020). This prevents a characterization of minimax risk uniformly across the full range of problem instances \( P_x \) that mix, unless one caps the mixing time to a fixed constant. Narrowing instead to LDS models in the sequel, we manage to succinctly carve out a basic problem family, with unbounded mixing time, and to characterize its minimax risk uniformly. One still pays
a price for sequential dependency, as this minimax risk turns out to be larger than its \text{Ind-Seq-LS} counterpart by a factor of the dimension \(n\).

Turning in addition to (b), by introducing (sufficiently many) resets, we can expand our data model substantially: we manage to lift most of our LDS assumptions and extend to other dynamical systems. Remarkably, we even show that for any controllable LDS—including ones that are unstable and hence grow exponentially in time—having sufficiently many resets guarantees that the risk exhibits, once again, the iid-like behavior of \(\sigma^2_{\xi}/(mT)\), up to mere constants.

### 3.4 Linear dynamical trajectories

Fix a \textit{dynamics matrix} \(A \in \mathbb{R}^{n \times n}\) and a \textit{control matrix} \(B \in \mathbb{R}^{n \times d}\). Consider the \(n\)-dimensional trajectory \(\{x_t\}_{t \geq 1}\) defined by the linear dynamical system:

\[
x_t = Ax_{t-1} + Bw_t, \quad \text{where } w_t \sim N(0, I_d), \quad \text{for } t \geq 1,
\]

(3.8)

taking \(x_0 = 0\) by convention. We assume that the noise process \(\{w_t\}_{t \geq 1}\) is independent across time, i.e., that \(w_t \perp w_{t'}\) whenever \(t \neq t'\). Overloading notation, let the matrix \(\Sigma_t(A, B) := \sum_{k=0}^{t-1} A^k BB^T(A^k)^T\) denote the covariance of \(x_t\), and let the matrix \(\Gamma_t(A, B) := \frac{1}{t} \sum_{k=1}^{t} \Sigma_k(A, B)\) denote the average covariance. Denote by \(P^{A, B}_x\) the distribution over the trajectory \(\{x_t\}_{t \geq 1}\), and let \(\{x_t^{(i)}\}_{i \geq 1}\) for \(i \geq 1\) denote independent draws from \(P^{A, B}_x\). When \(B = I_n\), we use the respective shorthand notation \(\Sigma_t(A), \Gamma_t(A), \text{ and } P^A_x\).

Modeling regression covariates as linear dynamical trajectories gives us the LDS-LS problem, a specialization of Seq-LS (Problem 3.1):

\textbf{Problem 3.3 (LDS-LS).} Assume a dynamics matrix \(A \in \mathbb{R}^{n \times n}\), a control matrix \(B \in \mathbb{R}^{n \times d}\), and a corresponding linear dynamical covariate distribution \(P^{A, B}_x\) in the linear regression model (3.1). Fix an evaluation horizon \(T'\). On input \(m\) labeled trajectories of length \(T\), drawn from this model, in the form of examples \(\{(x_t^{(i)}, y_t^{(i)})\}_{i=1,t=1}^{m,T}\), output a hypothesis \(\hat{f}_{m,T}\) that minimizes \(L(f_{m,T}; T', P^{A, B}_x)\).

Let \(P^{A, B}_{x,t}\) be the marginal distribution of \(x_t\) under \(P^{A, B}_x\) at each \(t \geq 1\). The natural decorrelated baseline for LDS-LS is a corresponding specialization of \text{Ind-Seq-LS} (Problem 3.2) to LDS trajectories:

\textbf{Problem 3.4 (Ind-LDS-LS).} Assume a dynamics matrix \(A \in \mathbb{R}^{n \times n}\), a control matrix \(B \in \mathbb{R}^{n \times d}\), and a corresponding trajectory distribution \(P^{A, B}_x\). Consider covariates drawn independently from its marginals, i.e., assume the linear regression model (3.1) under the covariate sequence distribution \(\otimes_{t \geq 1} P^{A, B}_{x,t}\). Fix an evaluation horizon \(T'\). On input \(m\) labeled trajectories of length \(T\), drawn from this model, in the form of examples \(\{(x_t^{(i)}, y_t^{(i)})\}_{i=1,t=1}^{m,T}\), output a hypothesis \(\hat{f}_{m,T}\) that minimizes \(L(f_{m,T}; T', \otimes_{t \geq 1} P^{A, B}_{x,t})\).

\textbf{Learning dynamical systems.} LDS-LS generalizes linear system identification, the problem of recovering the dynamics \(A\) from data. The reduction follows by setting \(W_* = A\) and \(\xi_t^{(i)} = Bw_t^{(i)}\), so that \(y_t^{(i)} = x_{t+1}^{(i)}\). Note that when \(B\) has full row rank, the squared parameter error in the weighted \(BB^T\) norm \(\|\cdot\|_BB^T\) is simply the risk \(L(A; T', P^{A, B}_x)\) when \(T' = 1\). Recent related work typically assumes that \(B\) indeed has full row rank, but in later sections we touch on the more general case where this is not required, so long as the pair \((A, B)\) is controllable. Bounds in operator norm
are also easily obtainable from our proof techniques. However, our lower bounds will not inform the system identification problem specifically; our hardness results rely on decoupling $W_*$ from $A$ and $\xi_t^{(i)}$ from $u_{t+1}^{(i)}$, whereas this reduction naturally ties them.

4 Risk upper bounds

We establish risk upper bounds by studying the behavior of the ordinary least-squares estimator. The key technical definition that drives the analysis is a “small-ball” condition on covariate sequences:

**Definition 4.1** (Trajectory small-ball (TrajSB)). Fix a trajectory length $T \in \mathbb{N}_+$, a parameter $k \in \{1, \ldots, T\}$, positive definite matrices $\{\Psi_j\}_{j=1}^{T/k} \subset \text{Sym}^n_{>0}$, and constants $c_{sb} > 0$, $\alpha \in (0, 1]$. The distribution $P_x$ satisfies the $(T, k, \{\Psi_j\}_{j=1}^{T/k}, c_{sb}, \alpha)$-trajectory-small-ball (TrajSB) condition if:

1. $\frac{1}{(T/k)} \sum_{j=1}^{[T/k]} \Psi_j \preceq \Gamma_T(P_x)$,

2. $\{x_t\}_{t \geq 1}$ is adapted to a filtration $\{\mathcal{F}_t\}_{t \geq 1}$, and

3. for all $v \in \mathbb{R}^n \setminus \{0\}$, $j \in \{1, \ldots, T/k\}$ and $\varepsilon > 0$:

$$
\mathbb{P}_{x \sim P_x} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{j} \langle v, x_t \rangle^2 \leq \varepsilon \cdot v^T \Psi_j v \mid \mathcal{F}_{(j-1)k} \right\} \leq (c_{sb} \varepsilon)^\alpha \text{ a.s.} \quad (4.1)
$$

Above, $\mathcal{F}_0$ is understood to be the minimal $\sigma$-algebra. Additionally, the distribution $P_x$ satisfies the $(T, k, \Psi, c_{sb}, \alpha)$-TrajSB condition if it satisfies $(T, k, \{\Psi_j\}_{j=1}^{T/k}, c_{sb}, \alpha)$-TrajSB with $\Psi_j = \Psi$. Finally, we call the parameter $k$ the excitation window.

In Definition 4.1, we typically consider the matrices $\Psi_j$ to be the sharpest almost-sure lower bound that we can specify (in the Loewner order) on the quantity $\mathbb{E}[\frac{1}{k} \sum_{t=(j-1)k+1}^{j} v^T x_t x_t^T \mid \mathcal{F}_{(j-1)k}]$. Section 4.1 lists examples of covariate sequence distributions $P_x$ that satisfy the TrajSB condition.

Definition 4.1 draws inspiration from the block martingale small-ball condition from Simchowitz et al. (2018). There are two main differences: (a) we consider the small-ball probability of the entire block $\frac{1}{k} \sum_{t=(j-1)k+1}^{j} \langle v, x_t \rangle^2$ at once, instead of the average of the small-ball probabilities $\frac{1}{k} \sum_{t=(j-1)k+1}^{j} \mathbb{P}\{\langle v, x_t \rangle^2 \leq \varepsilon \cdot v^T \Psi_j v \mid \mathcal{F}_{(j-1)k}\}$, and (b) equation (4.1) is required to hold at all scales $\varepsilon > 0$, instead of at a single resolution. We need the first modification (a) to prove optimal rates under many trajectories without assuming stability or ergodicity. Furthermore, condition (4.1) is implied by a bound on the average of small-ball probabilities (Proposition 4.4).\footnote{The block martingale small-ball condition from Simchowitz et al. (2018) is actually used only to establish a condition analogous to (4.1), suggesting that the latter is the natural quantity to consider.}

We need the second modification (b) in order to bound the expected value of the OLS risk; if the premise were only that (4.1) holds at a particular value of $\varepsilon$, then our results would weaken to give risk bounds only in high probability.\footnote{Such a high probability bound would not, in turn, imply a bound on the expected risk via integration over the tail. The reason is that the high probability bound would require that the number of data points $mT$ grow as $\log(1/\delta)$, where $\delta$ is the failure probability.}
The trajectory small-ball definition allows us to carve out conditions for learnability. A key quantity for what follows is the minimum eigenvalue of the ratio of two positive definite matrices:

$$\lambda(A, B) := \lambda_{\min}(B^{-1/2}AB^{-1/2}), \ A, B \in \text{Sym}_{>0}^n.$$  \hfill (4.2)

Our various upper bounds statements build on the following general lemma:

**Lemma 4.1** (General OLS upper bound). There are universal positive constants $c_0$ and $c_1$ such that the following holds. Suppose that $P_x$ satisfies the $(T, k, \{\Psi_j\}_{j=1}^{T/k}, c_{sb}, \alpha)$-TrajSB condition (Definition 4.1). Put $S := \lfloor T/k \rfloor$ and $\Gamma_t := \Gamma_t(P_x)$ for $t \in \mathbb{N}$. Fix any $\Gamma \in \text{Sym}_{>0}^n$ satisfying $\sum_{j=1}^S \Psi_j \lesssim \Gamma \lesssim \Gamma_T$, and let $\mu(\{\Psi_j\}_{j=1}^S, \Gamma)$ denote the geometric mean of the minimum eigenvalues $\{\lambda(\Psi_j, \Gamma)\}_{j=1}^S$, i.e.,

$$\mu(\{\Psi_j\}_{j=1}^S, \Gamma) := \left[ \prod_{j=1}^S \lambda(\Psi_j, \Gamma) \right]^{1/S}.$$ \hfill (4.3)

Suppose that:

$$n \geq 2, \quad mT/kn \geq c_0 \max \left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta(\Gamma, \Gamma_T)\mu(\{\Psi_j\}_{j=1}^S, \Gamma)} \right) \right\}. \hfill (4.4)$$

Then, for any $\Gamma' \in \text{Sym}_{>0}^n$:

$$\mathbb{E}[\|\hat{W}_{m,T} - W_*\|^2_{\Gamma'}] \leq c_1 c_{sb} \sigma_x^2 \cdot \frac{pm}{mT \alpha \Delta(\Gamma, \Gamma')} \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta(\Gamma, \Gamma_T)\mu(\{\Psi_j\}_{j=1}^S, \Gamma)} \right). \hfill (4.5)$$

The proof of Lemma 4.1 blends ideas from the analysis of random design linear regression (Hsu et al., 2014; Oliveira, 2016; Mourtada, 2019) with techniques from linear system identification (Simchowitz et al., 2018; Sarkar and Rakhlin, 2019; Faradonbeh et al., 2018; Dean et al., 2020). Note that Lemma 4.1 makes no explicit assumptions on the ergodicity of the process $P_x$. The role of $P_x$ is instead succinctly captured by the trajectory small-ball condition, together with the minimum eigenvalue quantities that appear in the bound. The proof of Lemma 4.1 also yields bounds on the risk that hold with high probability; we only present bounds in expectation for simplicity. Finally, if the square norm $\|X\|_{\Gamma_T}^2$ is defined to be $\lambda_{\max}(XMX^T)$ instead of $\text{tr}(XMX^T)$, then (4.5) holds with the expression $p + n$ replacing $pn$ in the numerator.

As long as the process $P_x$ satisfies the trajectory small-ball condition with excitation window $k = T$, Lemma 4.1 (with $\Psi_1 = \Gamma = \Gamma_T(P_x)$) immediately yields the following result for learning from many trajectories in the Seq-LS problem:

**Theorem 4.2** (Upper bound for Seq-LS, many trajectories). There are universal positive constants $c_0$ and $c_1$ such that the following holds. Suppose that $P_x$ satisfies the trajectory small-ball condition (Definition 4.1) with parameters $(T, T, \Gamma_T(P_x), c_{sb}, \alpha)$. If:

$$n \geq 2, \ m \geq c_0 n \max \left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \log \left( \frac{\max\{e, c_{sb}\}}{\alpha} \right) \right\},$$

then, for any $\Gamma' \in \text{Sym}_{>0}^n$:

$$\mathbb{E}[\|\hat{W}_{m,T} - W_*\|^2_{\Gamma'}] \leq c_1 c_{sb} \sigma_x^2 \cdot \frac{pm}{mT \alpha \Delta(\Gamma_T(P_x), \Gamma')} \log \left( \frac{\max\{e, c_{sb}\}}{\alpha} \right). \hfill (4.6)$$
This result provides the upper bound for the summary statement Theorem 1.1. To interpret the bound (4.6), suppose that \( c_{sb} \) and \( \alpha \) are universal constants. Then, the requirement on \( m \) simplifies to \( m \gtrsim n \). Under any strict evaluation horizon \( T' \leq T \), taking \( \Gamma' = \Gamma_{T'}(P_x) \), the risk \( \mathbb{E}[L(\hat{W}_{m,T}; T', \mathcal{P}_x)] \) scales as \( \sigma_x^2 \sigma_{\mathcal{P}}n/\max(mT, \lambda_{\min}(\Gamma_{T}(P_x))) \). The lower bound for Theorem 1.1 follows from the fact that iid linear regression is a special case of Seq-LS.

Meanwhile, to obtain guarantees for parameter recovery, consider taking \( \Gamma' = I_n \). Then Theorem 4.2 implies that the parameter error \( \mathbb{E}[[\hat{W}_{m,T} - W_*]^2] \) scales as \( \sigma_x^2 pm/(mT) \). Note that operator norm bounds on parameters also hold, with the expression \( p + n \) replacing \( pn \) in the bound.

Lemma 4.1 also yields a bound for Ind-Seq-LS, assuming polynomial growth of the time-\( t \) covariances \( \Sigma_t \) (3.3). To state the result, let \( \phi : [1, \infty) \times [0, \infty) \to [1, \infty) \) be defined as:

\[
\phi(a, x) := \begin{cases} 1 & \text{if } x \leq 1, \\ ax & \text{a.e.} \end{cases}
\]

Note that \( 1 \leq \phi(a, x) \leq \max\{ax, 1\} \).

**Theorem 4.3 (Upper bound for Ind-Seq-LS).** There are universal positive constants \( c_0 \) and \( c_1 \) such that the following holds. Fix any sequence of distributions \( \{P_{x,t}\}_{t \geq 1} \), and let \( \Sigma_t := \mathbb{E}_{x,t \sim P_{x,t}}[x_t x_t^T] \) for \( t \in \mathbb{N}_+ \). Suppose there exists \( c_{sb} > 0 \) and \( \alpha \in (0, 1] \) such that for all \( v \in \mathbb{R}^n \setminus \{0\} \), \( \varepsilon > 0 \) and \( t \in \mathbb{N}_+ \):

\[
\mathbb{P}_{x_1 \sim P_{x,1}} \left\{ (v, x_t)^2 \leq \varepsilon \cdot v^T \Sigma_t v \right\} \leq (c_{sb} \varepsilon)^\alpha.
\]

(4.8)

Furthermore, suppose there exists a \( c_\beta \geq 1 \) and \( \beta \geq 0 \) such that for all \( s, t \in \mathbb{N}_+ \) satisfying \( s \leq t \):

\[
\frac{1}{\Lambda(\Sigma_s, \Sigma_t)} \leq c_\beta (t/s)^\beta.
\]

(4.9)

If:

\[
n \geq 2, \quad mT \geq c_0 n \max\left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \left( \beta + \log\left( \frac{\max\{e, c_{sb}^\beta c_\beta\}}{\alpha} \right) \right) \right\},
\]

then, for \( P_x = \otimes_{t \geq 1} P_{x,t} \):

\[
\mathbb{E}[L(\hat{W}_{m,T}; T', P_x)] \leq c_1 c_{sb} \sigma_x^2 c_\beta e^\beta \cdot \frac{pm}{mT} \alpha \cdot \phi\left(c_\beta (\beta + 1), (T'/T)^\beta\right) \left[ \beta + \log\left( \frac{\max\{e, c_{sb}^\beta c_\beta\}}{\alpha} \right) \right].
\]

(4.10)

Consider specializing Theorem 4.3 to the case when \( \Sigma_t = \Sigma \) for all \( t \in \mathbb{N}_+ \). Doing so yields random design linear regression from \( mT \) covariates drawn iid from \( P_{x,1} \). The growth condition (4.9) is trivially satisfied with \( c_\beta = 1 \) and \( \beta = 0 \). The small-ball assumption (4.8) simplifies to \( \mathbb{P}_{x_1 \sim P_{x,1}}[|v, x_1|] \leq \varepsilon |v| \leq (\sqrt{\sigma_x} e^\alpha/2)^2 \) for all \( v \neq 0 \) and \( \varepsilon > 0 \), which matches Mourtada (2019, Assumption 1) up to a minor redefinition of the constants \( c_{sb}, \alpha \). Treating \( c_{sb} \) and \( \alpha \) as constants, the conclusion of Theorem 4.8 in this setting is that \( \mathbb{E}[||\hat{W}_{m,T} - W_*||^2] \leq \sigma_x^2 pm/(mT) \) as long as \( n \geq 2 \) and \( mT \gtrsim n \), which recovers Mourtada (2019, Proposition 2).

On the other hand, Theorem 4.8 does not require that the covariates are drawn iid from the same distribution, allowing the time-\( t \) covariances \( \Sigma_t \) to grow polynomially. As an example, suppose that
\[ \Sigma_t = t^\beta \cdot I_n \text{ for some } \beta > 0. \text{ In this case, } 1/\Lambda(\Sigma_x, \Sigma_t) = (t/s)^\beta, \text{ so we can take } c_\beta = 1 \text{ in (4.9). Again treating } c_{sb} \text{ and } \alpha \text{ as constants and taking } T' \leq T, \text{ we have } \mathbb{E}[L(\hat{W}_{m,T}; T', P_x)] \leq \sigma^2 \beta e^{\beta} \cdot pn/(mT) \text{ as long as } mT \gtrsim \beta n. \text{ If } \beta \text{ is also considered a constant, then we further have the risk bound } \mathbb{E}[L(W_{m,T}; T', P_x)] \leq \sigma^2 \beta e^{\beta} \cdot pn/(mT). \text{ This matches the minimax rate for iid linear regression.}

It is natural to ask if the covariance growth condition (4.9) is needed under strict evaluation horizons \( T' \leq T. \) In Section 5, we show that if the covariances are set to \( \Sigma_t = 2^t \cdot I_n \) and \( P_{x,t} = N(0, \Sigma_t) \) (satisfying (4.8)), then the minimax risk \( R(m, T, T; \{ \otimes_{t \geq 1} P_{x,t} \}) \) must scale at least \( 2^{cn/m}/T \) whenever \( m \lesssim n \), for some positive constant \( c \). Sub-exponential growth rates are therefore necessary for polynomial sample complexity. Determining the optimal dependence of \( \beta \) in (4.10) is left to future work.

Note that Theorem 4.3 is most interesting either when trajectories are few \( (m \lesssim n) \) or evaluations are extended \( (T' > T) \). When \( m \gtrsim n \) and \( T' \leq T \), one can usually apply Theorem 4.2 with \( \Gamma' = \Gamma_{T}(P_x) \) instead, and avoid placing any requirements on the growth of covariances.

### 4.1 Examples of trajectory small-ball distributions

We now turn to specific examples of distributions \( P_x \) which satisfy the trajectory small-ball condition. First is the example introduced in Section 3.3, where \( x_1 \) is drawn from a multivariate Gaussian and subsequently copied as \( x_t = x_{t-1} \) for all \( t \geq 2 \):

**Example 4.1 (Copies of a Gaussian draw).** Let \( \Sigma \in \text{Sym}^n_{>0} \), and let \( P_x \) denote the process \( x_1 \sim N(0, \Sigma) \) and \( x_t = x_{t-1} \) for \( t \geq 2 \). Fix any \( T \in \mathbb{N}_+ \). Then \( P_x \) satisfies the \((T, T, \Sigma, e, \frac{1}{2})\)-TrajSB condition.

Note that this process only satisfies the trajectory small-ball condition with excitation window \( k = T \). In other words, the conditional distribution \( x_{t+k} \mid x_t \) for \( k \geq 1 \) (a Dirac distribution on \( x_t \)) contains no excitation as needed for learning. This example can actually be generalized to arbitrary Gaussian processes indexed by time:

**Example 4.2 (Gaussian processes).** Let \( P_x \) be a Gaussian process indexed by time, i.e., for every finite index set \( I \subset \mathbb{N}_+ \), the collection of random variables \( (x_t)_{t \in I} \) is jointly Gaussian. Let \( T_{nd} := \inf \{ t \in \mathbb{N}_+ \mid \det(\mathbb{E}[x_t x_t^T]) \neq 0 \} \), and suppose \( T_{nd} \) is finite. There exists a positive universal constant \( c \) such that the following is true. Fix a \( T \in \mathbb{N}_+ \) satisfying \( T \geq T_{nd} \). Then \( P_x \) satisfies the \((T, T, \Gamma_T(P_x), c, \frac{1}{2})\)-TrajSB condition.

Our next example involves independent, but not identically distributed, covariates:

**Example 4.3 (Independent Gaussians).** Let \( \{\Sigma_t\}_{t \geq 1} \subset \text{Sym}^n_{>0} \), and let \( P_x = \otimes_{t \geq 1} N(0, \Sigma_t) \). Fix a \( T \in \mathbb{N}_+ \). Then \( P_x \) satisfies the \((T, 1, \{\Sigma_t\}_{t=1}^T, e, \frac{1}{2})\)-TrajSB condition.

Example 4.3 allows us to select \( k = 1 \), reflecting the independence of the covariates across time.

We can also craft an example around a process that does not mix, but that still exhibits an excitation window of \( k = 2 \):

**Example 4.4 (Alternating halfspaces).** Suppose that \( n \geq 4 \) is even, and let \( u_1, \ldots, u_n \) be a fixed orthonormal basis of \( \mathbb{R}^n \). Put \( U_0 = \text{span}(u_1, \ldots, u_n/2) \) and \( U_1 = \text{span}(u_n/2+1, \ldots, u_n) \). Let

\[
\xi_t \sim \text{Bern}(\frac{1}{2}), \quad i_{t+1} = i_t \mod 2 \text{ for } t \in \mathbb{N}_+, \text{ and let } P_x \text{ denote the process with conditional distribution } x_t | i_t \text{ uniform over the spherical measure on } U_{i_t} \cap S^{n-1}. \text{ For any } T \geq 2, \text{ the process } P_x \text{ satisfies the } (T, 2, I_n/(2n), e, \frac{1}{2})\)-TrajSB condition.

\(^3\)Some regularity is needed when under extended evaluations \( T' > T \), otherwise the risk could be arbitrarily large.
To see that the covariate distribution \( \{x_t\} \) does not mix, observe that the marginal distribution for all \( t \) is uniform on \( S^{n-1} \), whereas the conditional distribution \( x_{t+k} | x_t \) for any \( k \in \mathbb{N}_+ \) is either uniform on \( U_0 \cap S^{n-1} \) or uniform on \( U_1 \cap S^{n-1} \). Although it does not mix at all, the trajectory supplies ample excitation for learning in any mere two steps.

Even for a process that does mix, it may exhibit an excitation window far smaller than its mixing time. The following sets up such an example, where again where sufficient excitation is provided with \( k = 2 \) steps:

**Example 4.5** (Normal subspaces). Suppose that \( n \geq 3 \). Let \( u_1, ..., u_n \) be a fixed orthonormal basis in \( \mathbb{R}^n \), and let \( U_{-i} := \text{span}\{\{u_j\}_{j \neq i}\} \) for \( i \in \{1, ..., n\} \). Consider the Markov chain \( \{i_t\}_{t \geq 1} \) defined by \( i_1 \sim \text{Unif}\{\{1, ..., n\}\} \), and \( i_{t+1} | i_t \sim \text{Unif}\{\{1, ..., n\} \setminus \{i_t\}\} \). Let \( P_x \) denote the process with conditional distribution \( x_t | i_t \) uniform over the spherical measure on \( U_{-i_t} \cap S^{n-1} \). For any \( T \geq 2 \), the process \( P_x \) satisfies the \((T, 2, I_n/(4n - 4), e, \frac{1}{2})\)-TrajSB condition.

In this example, a straightforward computation (detailed in Proposition B.14) shows that the mixing time \( \tau_{\text{mix}}(\varepsilon) \) of the Markov chain \( \{i_t\}_{t \geq 1} \) scales as \( \log_n(1/\varepsilon) \). In most analyses which rely on mixing time arguments, one requires that the mixing time resolution \( \varepsilon \) tends to zero as either the amount of data and/or probability of success increases; as a concrete example, Duchi et al. (2012, Eq. 3.2) suggests to set \( \varepsilon = 1/\sqrt{T} \), where \( T \) is the number of samples drawn from the underlying distribution. On the other hand, the trajectory small-ball condition in Example 4.5 holds with a short excitation window of length \( k = 2 \), independently of \( T \).

Next we consider linear dynamical systems. As setup, we first define the notion of controllability for a pair of dynamics matrices \((A, B)\):

**Definition 4.2** (Controllability). Let \((A, B)\) be a pair of matrices with \( A \in \mathbb{R}^{n \times n} \) and \( B \in \mathbb{R}^{n \times d} \). For \( k \in \{1, ..., n\} \), we say that \((A, B)\) is \( k\)-step controllable if the matrix:

\[
\begin{bmatrix}
B & AB & A^2B & \cdots & A^{k-1}B
\end{bmatrix} \in \mathbb{R}^{n \times kd}
\]

has full row rank.

The classical definition of controllability in linear systems (cf. Rugh, 1996, Chapter 25) is equivalent to \( n\)-step controllability. Definition 4.2 allows the system to be controllable in fewer than \( n \) steps. Also note that \( k \) is restricted to \( \{1, ..., n\} \), since if a system is not \( n\)-step controllable, it will not be \( n'\)-step controllable for any \( n' > n \) (by the Cayley-Hamilton theorem). A few special cases of interest to note are as follows. If \( B \) has rank \( n \), then \((A, B)\) is trivially one-step controllable for any \( A \). On the other hand, if \((A, B)\) are in canonical controllable form (i.e., \( A \) is the companion matrix associated with the polynomial \( p(z) = a_0 + a_1z + \ldots + a_{n-1}z^{n-1} + z^n \) and \( B \) is the \( n \)-th standard basis vector), then \((A, B)\) is \( n\)-step controllable. The latter corresponds directly to the state-space representation of autoregressive processes of order \( n \), e.g. AR(\( n \)).

**Example 4.6** (Linear dynamical systems). Let \((A, B)\) with \( A \in \mathbb{R}^{n \times n} \) and \( B \in \mathbb{R}^{n \times d} \) be \( k_c\)-step-controllable (Definition 4.2). Let \( P_x^{A, B} \) be the linear dynamical system defined in (3.8). Fix any \( T, k \in \mathbb{N}_+ \) satisfying \( T \geq k \geq k_c \). Then, \( P_x^{A, B} \) satisfies the \((T, k, \Gamma_k(A, B), e, \frac{1}{2})\)-TrajSB condition.

---

4For concreteness, given a discrete-time Markov chain over a finite state-space \( S \) with transition matrix \( P \) and stationary distribution \( \pi \), we define the mixing time as:

\[
\tau_{\text{mix}}(\varepsilon) := \inf\{k \in \mathbb{N} | \sup_{\mu \in \mathcal{P}(S)} \|\mu P^k - \pi\|_\text{tv} \leq \varepsilon\}.
\]

Here, \( \mathcal{P}(S) \) denotes the set of all probability distributions over \( S \), and \( \|\cdot\|_\text{tv} \) denotes the total variation norm over distributions.
In all of the examples so far, the time-\( t \) marginal distribution of covariates \( x_t \) has either been a multivariate Gaussian or a spherical measure. To underscore the generality of the small-ball method, we can create additional examples where this is not the case. In what follows, we consider Volterra series (Mathews and Sicuranza, 2000), which generalize the classical Taylor series to causal sequences. Analogous to how polynomials can approximate continuous functions arbitrarily well on a compact set, Volterra series can approximate signals that depend continuously (and solely) on their history over a bounded set of inputs (cf. Rugh, 1981, Section 1.5).

Example 4.7 (Degree-\( D \) Volterra series). Fix a \( D \in \mathbb{N}_+ \). Let \( \{c^{(d,\ell)}_{i_1,\ldots,i_d}\}_{i_1,\ldots,i_d,\ell \in \mathbb{N}} \) for \( d \in \{1,\ldots,D\} \) and \( \ell \in \{1,\ldots,n\} \) denote arbitrary rank-\( d \) arrays. Let \( \{w^{(\ell)}_t\}_{t \geq 0} \) be iid \( \mathcal{N}(0,1) \) random variables for \( \ell \in \{1,\ldots,n\} \). Consider the process \( P_x \), where for \( t \geq 1 \), the \( \ell \)-th coordinate of \( x_t \), denoted \( (x_t)_\ell \), is:

\[
(x_t)_\ell = \sum_{d=1}^D \sum_{i_1,\ldots,i_d=0}^{t-1} c^{(d,\ell)}_{i_1,\ldots,i_d} \prod_{d'=1}^d w^{(\ell)}_t w^{(\ell)}_{t-i_d-1} \tag{4.11}
\]

Let \( T_{nd} := \inf \{ t \in \mathbb{N}_+ \mid \det(\Gamma_{t}(P_x)) \neq 0 \} \), and suppose \( T_{nd} \) is finite. There is a constant \( c_D > 0 \), depending only on \( D \), such that for any \( T \geq T_{nd} \), \( P_x \) satisfies the \((T,T,\Gamma_T(P_x),c_D,1/(2D))\)-TrajSB condition.

The main idea behind Example 4.7 is that, while \( x_t \) is certainly not Gaussian, the quadratic form \( \sum_{t=1}^T \langle v, x_t \rangle^2 \) is a degree at most 2\( D \) polynomial in \( \{w^{(\ell)}_t\}_{t=0}^{T-1} \). It will hence exhibit anti-concentration, according to a landmark result from Carbery and Wright (2001). The same result actually provides an immediate extension of this example—as well as the previous examples—to noise distributions with log-concave densities, such as Laplace or uniform noise.

We next present a special case of the Volterra series, where we can choose the excitation window \( k \) in the small-ball definition strictly between the endpoints 1 and \( T \). To set up, a few more definitions are needed:

Definition 4.3. Fix an integer \( d \in \mathbb{N}_+ \). A rank-\( d \) array of coefficients \( \{c_{i_1,\ldots,i_d}\}_{i_1,\ldots,i_d,\ell \in \mathbb{N}} \) is called:

(a) symmetric if \( c_{i_1,\ldots,i_d} = c_{\pi(i_1,\ldots,i_d)} \) for any permutation \( \pi \) of indices \( i_1,\ldots,i_d \in \mathbb{N} \),
(b) traceless if \( c_{i_1,\ldots,i_i} = 0 \) for all \( i \in \mathbb{N} \), and
(c) non-degenerate if there exists an \( k_{nd} \in \mathbb{N}_+ \) such that the following set is non-empty:

\[
\{ (i_1,\ldots,i_d) \mid c_{i_1,\ldots,i_d} \neq 0, i_1,\ldots,i_d \in \{0,\ldots,k_{nd}-1\} \}.
\]

The smallest \( k_{nd} \) such that \( \{c_{i_1,\ldots,i_d}\} \) is the non-degeneracy index.

Example 4.8 (Degree-2 Volterra series). Consider the following process \( P_x \). Let \( \{c^{(\ell)}_{ij}\}_{i,j \geq 0} \) for \( \ell \in \{1,\ldots,n\} \) be symmetric, traceless, non-degenerate arrays (Definition 4.3). Let \( \{w^{(\ell)}_t\}_{t \geq 0} \) be iid \( \mathcal{N}(0,1) \) random variables for \( \ell \in \{1,\ldots,n\} \). For \( t \geq 1 \), the \( \ell \)-th coordinate of \( x_t \), denoted \( (x_t)_\ell \), is:

\[
(x_t)_\ell = \sum_{i=0}^{t-1} \sum_{j=0}^{t-1} c^{(\ell)}_{ij} w^{(\ell)}_{t-i-1} w^{(\ell)}_{t-j-1} \tag{4.12}
\]

Let \( k_{nd} \in \mathbb{N}_+ \) denote the smallest non-degeneracy index for all \( n \) arrays. There is a universal positive constant \( c \) such that for any \( T \) and \( k \) satisfying \( T \geq k \geq k_{nd} \), \( P_x \) satisfies the \((T,k,\Gamma_k(P_x),c,1/4)\)-TrajSB condition.
The assumptions pulled in from Definition 4.3 help simplify the construction of an almost sure lower bound for conditional covariances \( \mathbb{E}[\frac{1}{k} \sum_{t=(j-1)k+1}^{jk} x_t x'_T | \mathcal{F}_{(j-1)k}] \), to establish that Example 4.8 satisfies the trajectory small-ball condition. We believe that generalizations to higher degree Volterra series with \( k \) strictly between 1 and \( T \) are possible by more involved calculations.

Of course, many other examples are possible. To help in recognizing them, the following statement shows that condition (4.1) in the trajectory small-ball definition can be verified by separately establishing small-ball probabilities for the conditional distributions:

**Proposition 4.4** (Average small-ball implies trajectory small-ball). Fix \( T \in \mathbb{N}_+ \), \( k \in \{1, \ldots, T\} \), \( \{\Psi_j\}_{j=1}^{\lceil T/k \rceil} \subset \text{Sym}^n_{>0} \), \( c_{sb} > 1 \), and \( \alpha \in (0, 1] \). Let \( P_x \) be a covariate distribution, with \( \{x_t\}_{t \geq 1} \) adapted to a filtration \( \{\mathcal{F}_t\}_{t \geq 1} \). Suppose for all \( v \in \mathbb{R}^n \setminus \{0\} \), \( j \in \{1, \ldots, \lceil T/k \rceil \} \), and \( \varepsilon > 0 \):

\[
\frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \mathbb{P}_{x_t \sim P_x} \left\{ (v, x_t)^2 \leq \varepsilon \cdot v^T \Psi_j v \left| \mathcal{F}_{(j-1)k} \right. \right\} \leq (c_{sb} \varepsilon)^\alpha \text{ a.s.,} \tag{4.13}
\]

where \( \mathcal{F}_0 \) is the minimal \( \sigma \)-algebra. Then, for all \( v \in \mathbb{R}^n \setminus \{0\} \), \( j \in \{1, \ldots, \lceil T/k \rceil \} \), and \( \varepsilon > 0 \):

\[
\mathbb{P}_{\{x_t\} \sim P_x} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} (v, x_t)^2 \leq \varepsilon \cdot v^T \Psi_j v \left| \mathcal{F}_{(j-1)k} \right. \right\} \leq (c_{sb}' \varepsilon)^\alpha \text{ a.s.,} \tag{4.14}
\]

where \( c_{sb}' := c_{sb}/(1 - 1/c_{sb})^{1/\alpha} \).

Equation (4.13) can be easier to verify than (4.1), since the former allows one to reason about each conditional distribution individually, whereas the latter requires reasoning about the entire excitation window altogether.

Considering any of the small-ball examples in this section, recall that when the excitation window \( k \) and the horizon \( T \) are equal, Theorem 4.2 provides an upper bound on the risk of OLS estimation for the corresponding Seq-LS problem. Specifically, for Example 4.1 and Example 4.6 with \( k = T \), if \( T' = T \) and trajectories are abundant \( (m \gtrsim n) \), then the OLS estimator’s rate \( \sigma^2_{\xi} pm/(mT) \) matches its behavior in iid linear regression. Meanwhile, for the degree-\( D \) Volterra series (Example 4.7), we require that \( m \gtrsim c_D \cdot n \), and the OLS risk bound scales as \( \sigma^2_{\xi} c_D' \cdot pm/(mT) \), for constants \( c_D \) and \( c_D' \) that only depend on \( D \).

In order to cover scenarios in which trajectories may be relatively scarce, namely \( m \lesssim n \), we need additional structure. More technically, when the small-ball condition is satisfied with \( k < T \), one needs to further control the various eigenvalues that appear in Lemma 4.1 in order to bound the risk of OLS. Specifically for Ind-Seq-LS, a covariate growth assumption suffices: Example 4.3 combined with Theorem 4.3 yields an OLS risk bound. Furthermore, both Example 4.4 and Example 4.5 can be immediately combined with Lemma 4.1, since the matrices \( \Psi_j \) in these examples are bounded above and below by \( \Gamma(T)(P_x) \) up to universal constant factors. But arbitrarily large risk can still be realized in the general Seq-LS problem, even when the trajectory small-ball condition is satisfied. To study the behavior of OLS across all regimes of trajectory count \( m \), example dimensions \( p \) and \( n \), and trajectory lengths \( T \) and \( T' \), we focus specifically on linear dynamical systems and the LDS-LS problem for our remaining upper bounds.
4.2 Upper bounds for linear dynamical systems

In this section, we focus exclusively on dynamics \( P^{A,B} \) described by a linear dynamical system (3.8). As discussed previously, in order to apply Lemma 4.1 in the few trajectories regime when \( m < n \), we must (a) show that the process \( P^{A,B} \) satisfies the trajectory small-ball condition, and (b) bound the various eigenvalues which appear in Lemma 4.1. Example 4.6 establishes that \( P^{A,B} \) satisfies the \((T, k, \Gamma_k(A, B), e, 1/2)\)-TrajSB condition, as long as \((A, B)\) is \( k_c \)-step controllable and \( k \geq k_c \), thus taking care of (a). To handle (b), we introduce additional assumptions on the dynamics matrices \((A, B)\):

**Assumption 4.1** (Marginal instability). The dynamics matrix \( A \) in LDS-LS is marginally unstable. That is, \( \rho(A) \leq 1 \), where \( \rho(A) \) denotes the spectral radius of \( A \).

**Assumption 4.2** (Diagonalizability). The dynamics matrix \( A \) in LDS-LS is complex diagonalizable as \( A = SDS^{-1} \), where \( S \in \mathbb{C}^{n \times n} \) is invertible and \( D \in \mathbb{C}^{n \times n} \) is a diagonal matrix comprising the eigenvalues of \( A \).

**Assumption 4.3** (One-step controllability). The control matrix \( B \) in LDS-LS has full row rank, i.e., \( \text{rank}(B) = n \). Equivalently, the pair \((A, B)\) is one-step controllable (Definition 4.2).

Assumption 4.1 is fairly standard in the literature. Going beyond the regime \( \rho(A) = 1 + \varepsilon \), where \( \varepsilon \lesssim 1/T \), requires additional technical assumptions on the dynamics matrix \( A \) that we choose to avoid in the interest of simplicity; the OLS estimator is in general not a consistent estimator when \( \rho(A) > 1 \) and \( m = 1 \) (cf. Phillips and Magdalinos (2013); Sarkar and Rakhlin (2019)). The condition \( \rho(A) \lesssim 1 \) is often referred to as marginal stability in other work. We choose to call it marginally unstable instead, to emphasize the fact that such systems, namely at \( \rho(A) = 1 \), may not be ergodic and that the state can grow unbounded (e.g. have magnitude roughly \( t^n \) at time \( t \)).

Diagonalizability (Assumption 4.2) is less standard in the literature. We use it together with Assumption 4.1 and Assumption 4.3 to establish that \( \Delta(k, t; A, B) := \Delta(\Gamma_k(A, B), \Gamma_t(A, B)) \gtrsim c \cdot k/t \) whenever \( k \leq t \), where \( c \) is a constant that depends only on \( A \) and \( B \) (and not \( k \) and \( t \)). In previous work on linear system identification, the term \( \Delta(k, t; A, B) \) only appears under a logarithm, and so coarser analyses in the general case can still establish polynomial rates (cf. Simchowitz et al. (2018, Proposition A.1), Sarkar and Rakhlin (2019, Proposition 7.6)).

However, by allowing for evaluation lengths \( T' > 1 \), the dependence on \( \Delta(k, t; A, B) \) is no longer entirely confined under a logarithm (cf. Lemma 4.1). A sharp characterization is hence critical for deriving optimal rates. In Appendix A, we conjecture the correct scaling of \( \Delta(k, t; A, B) \) as a function of the ratio \( k/t \) and the largest Jordan block size of \( A \), based on numerical simulation.

One-step controllability (Assumption 4.3) is also an assumption commonly made in linear system identification. It is clear that some form of controllability is needed, otherwise learning may be impossible (e.g. consider the extreme case of \( B = 0 \)). General multi-step controllability does not suffice either: Tsiamis and Pappas (2021, Theorem 2) show that under a single trajectory \((m = 1)\), \( n \)-step controllability (where \( n \) remains the state dimension) does not ensure finite risk, and even a more robust controllability definition (Tsiamis and Pappas, 2021, Definition 3) cannot ensure risk bounds better than exponential in the dimension \( n \). Considering these barriers, we simply choose to rely on one-step controllability in the few-trajectory setting \((m \lesssim n)\).

Finally, we introduce a condition number quantity that will feature commonly in our bounds:

\[ \|A\| \leq n^{d/2}/T \]

for the operator norm of the parameter error in general, and this is likely not optimal.
**Definition 4.4.** For dynamics matrices \((A,B)\) in LDS-LS satisfying Assumption 4.2 and Assumption 4.3, the condition number \(\gamma(A,B)\) is defined as: \(\gamma(A,B) := \frac{\lambda_{\text{max}}(S^{-1}BB^TS^{-1})}{\lambda_{\text{min}}(S^{-1}BB^TS^{-1})}\).

### 4.2.1 Many trajectories

Our first result instantiates Theorem 4.2 in the special case of \(\Gamma' = I_n\), which yields a sharp bound for parameter recovery without requiring stability of the dynamics matrix \(A\):

**Theorem 4.5** (Parameter recovery upper bound for LDS-LS, many trajectories). There are universal positive constants \(c_0\) and \(c_1\) such that the following holds for any instance of LDS-LS. Suppose that \((A,B)\) is \(k_c\)-step controllable, If \(n \geq 2\), \(m \geq c_0 n\), and \(T \geq k_c\), then:

\[
E[\|\hat{W}_{m,T} - W_*\|_F^2] \leq c_1 \sigma_x^2 \cdot \frac{pm}{mT \cdot \lambda_{\text{min}}(\Gamma_T(A,B))}.
\]

Theorem 4.5 improves on existing linear system identification results in the following way: it replaces stability assumptions on the dynamics matrix \(A\) with a simpler assumption of relatively many trajectories \((m \gtrsim n)\), and it guarantees a rate that is inversely proportional to the total number of examples \(mT\) instead of only one example per trajectory. In other words, our analysis does not need to “discard” the data within a trajectory, which is the case in Dean et al. (2020, Proposition 1.1). Additionally, although OLS is generally not a consistent estimator from one trajectory \((m = 1)\) if the dynamics \(A\) are unstable, the results of Dean et al. (2020) imply consistency as \(m \to \infty\), i.e., that \(\hat{W}_{m,T}\) converges in probability to \(W_*\) as \(m \to \infty\). Theorem 4.5 adds that, provided \(m \gtrsim n\), OLS is consistent under unstable systems as \(T \to \infty\) as well, even if the trajectory count \(m\) remains finite. We will return to parameter recovery from relatively few trajectories \((m \lesssim n)\) by this section’s end.

We now look beyond an evaluation horizon of length one, and consider the setting with many trajectories \((m \gtrsim n)\). As noted previously, in order to handle an arbitrary evaluation horizon \(T'\) (in particular those that extend past the training horizon \(T\)), some constraint on the admissible dynamics matrices is needed to ensure that the minimax risk remains finite. Without assumptions, the quantity \(\Lambda(\Gamma_T(A,B), \Gamma_{T'}(A,B))\), whose inverse inevitably bounds the risk (3.2) from below, can be arbitrarily small whenever \(T' > T\), resulting in arbitrarily large risk. We will use our stated assumptions from the beginning of this section. The following specializes Theorem 4.2 to LDS-LS:

**Theorem 4.6** (Risk upper bound for LDS-LS, many trajectories). There are universal positive constants \(c_0\) and \(c_1\) such that the following holds for any instance of LDS-LS. Suppose that \((A,B)\) is \(k_c\)-step controllable. If \(n \geq 2\), \(m \geq c_0 n\), \(T \geq k_c\), and the evaluation horizon is strict \((T' \leq T)\), then:

\[
E[L(\hat{W}_{m,T}; T', p_{x}^{A,B})] \leq c_1 \sigma_x^2 \cdot \frac{pm}{mT}.
\]

On the other hand, suppose that \((A,B)\) satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with \(\gamma := \gamma(A,B)\) (Definition 4.4). If \(n \geq 2\), \(m \geq c_0 n\), and the evaluation horizon is extended \((T' > T)\), then:

\[
E[L(\hat{W}_{m,T}; T', p_{x}^{A,B})] \leq c_1 \sigma_x^2 \cdot \frac{pm}{mT} \cdot \frac{T'}{T}.
\]
Setting $T' = T$, Theorem 4.6 states that the risk of LDS-LS in the many trajectories regime satisfies $\mathbb{E}[L(\hat{W}_{m,T}; T, P^A_x)] \leq \sigma_x^2 \frac{pn \log(m \{\gamma n/m,e\})}{mT}$. This rate matches the corresponding independent baseline Ind-LDS-LS in the many trajectories regime. To see this, first observe that the marginal distribution $P_x$ at time $t \in \mathbb{N}_+$ is $N(0, \Sigma_t(A, B))$. Hence, the covariate distribution for Ind-LDS-LS corresponds to the product distribution $\otimes_{t \geq 1} N(0, \Sigma_t(A, B))$, which is an instance of a Gaussian process. Therefore, Example 4.2 combined with Theorem 4.2 yields that the Ind-LDS-LS problem also has a risk bound that scales as $\sigma_x^2 \frac{pn \log(m \{\gamma n/m,e\})}{mT}$ whenever $m \gtrsim n$. Put differently, the dependent structure of the covariate distribution $P_x$ in LDS-LS does not add any statistical overhead to the learning problem (compared to the independent learning problem Ind-LDS-LS), as long as $m \gtrsim n$.

### 4.2.2 Few trajectories

We now cover the regime in which relatively few training trajectories are available ($m \lesssim n$). Our first result bounds the OLS risk for the LDS-LS problem:

**Theorem 4.7** (Risk upper bound for LDS-LS, few trajectories). There are universal positive constants $c_0, c_1,$ and $c_2$ such that the following holds for any instance of LDS-LS. Suppose that $(A, B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma = \gamma(A, B)$ (Definition 4.4). If $n \geq 2$, $m \leq c_0 n$, and $mT \geq c_1 n \log(\max\{\gamma n/m,e\})$, then:

$$\mathbb{E}[L(\hat{W}_{m,T}; T', P^A_x)] \leq c_2 \sigma_x^2 \cdot \frac{pn \log(\max\{\gamma n/m,e\})}{mT} \cdot \phi\left(\gamma, \frac{c_1 n \log(\max\{\gamma n/m,e\})}{m} \cdot \frac{T'}{T}\right).$$

To interpret Theorem 4.7, consider $\gamma$ a constant and suppose that $T' = T$. Then Theorem 4.7 states that $\mathbb{E}[L(\hat{W}_{m,T}; T, P^A_x)] \leq c_2 \sigma_x^2 \cdot \frac{pn \log(\max\{\gamma n/m,e\})}{mT}$.

We now see that this LDS-LS risk is an extra $n \log^2(n/m)/m$ factor larger than the risk of the baseline problem Ind-LDS-LS:

**Theorem 4.8** (Risk upper bound for Ind-LDS-LS). There are universal positive constants $c_0, c_1,$ and $c_2$ such that the following holds for any instance of Ind-LDS-LS. Suppose that $(A, B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma = \gamma(A, B)$ (Definition 4.4). If $n \geq 2$ and $mT \geq c_1 n \log(\max\{\gamma, e\})$, then:

$$\mathbb{E}[L(\hat{W}_{m,T}; T', \otimes_{t \geq 1} P^A_x)] \leq c_2 \sigma_x^2 \cdot \frac{pn \gamma \log(\max\{\gamma, e\})}{mT} \cdot \phi\left(\gamma, \frac{T'}{T}\right).$$

Treating $\gamma$ as a constant and setting $T' = T$, Theorem 4.8 states that $\mathbb{E}[L(\hat{W}_{m,T}; T, \otimes_{t \geq 1} P^A_x)]$ scales as $\sigma_x^2 \frac{pn \gamma \log(\max\{\gamma, e\})}{mT}$, matching the risk of iid linear regression up to constant factors. In Section 5, we will see that the result of Theorem 4.7 is sharp up to constants, and therefore the LDS-LS problem is fundamentally more difficult than its corresponding baseline problem Ind-LDS-LS when trajectories are relatively scarce.

We conclude with our final upper bound, using our assumptions to generalize Simchowitz et al. (2018, Theorem 2.1) to the few-trajectory setting:

**Theorem 4.9** (Parameter recovery upper bound for LDS-LS, few trajectories). There are universal positive constants $c_0, c_1, c_2,$ and $c_3$ such that the following holds for any instance of LDS-LS. Suppose that $(A, B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma = \gamma(A, B)$ (Definition 4.4). If $n \geq 2$, and $mT \geq c_1 n \log(\max\{\gamma n/m,e\})$, then:

$$\mathbb{E}[\|\hat{W}_{m,T} - W_x\|^2_P] \leq c_2 \sigma_x^2 \cdot \frac{pn \log(\max\{\gamma n/m,e\})}{mT \cdot \lambda_{\min}(F_k(A, B))}, \quad k_* := \left\lfloor \frac{c_3 T}{n/m \cdot \log(\max\{\gamma n/m,e\})} \right\rfloor.$$
Theorem 4.9 complements Theorem 4.5; together they cover parameter recovery across all problem regimes. Again, operator norm bounds also hold with \( p + n \) in place of \( pn \).

5 Risk lower bounds

Our lower bounds rely on the following statement, that the expected trace inverse covariance—a classic quantity in asymptotic statistics—bounds the minimax risk from below:

**Lemma 5.1** (Expected trace of inverse covariance bounds risk from below). Fix \( m, T \in \mathbb{N}_+ \) and a set of covariate distributions \( \mathcal{P}_x \). Suppose that for every \( \mathcal{P}_x \in \mathcal{P}_x \), the data matrix \( X_{m,T} \in \mathbb{R}^{mT \times n} \) drawn from \( \otimes_{i=1}^m \mathcal{P}_x \) has full column rank almost surely. The minimax risk \( R(m, T, T'; \mathcal{P}_x) \) satisfies:

\[
R(m, T, T'; \mathcal{P}_x) \geq \sigma_x^2 p \cdot \sup_{\mathcal{P}_x \in \mathcal{P}_x} \mathbb{E}_{\otimes_{i=1}^m \mathcal{P}_x} \left[ \text{tr} \left( \Gamma^{1/2}_{T'}(\mathcal{P}_x)(X_{m,T}^T X_{m,T})^{-1} \Gamma^{1/2}_{T'}(\mathcal{P}_x) \right) \right].
\]

Lemma 5.1 is well known, possibly considered folklore; we state and prove it for completeness. Our proof is inspired by a recent argument from Mourtada (2019). It smooths over problem instances according to a Gaussian prior, and analytically characterizes the posterior distribution of the parameter \( W_x \) under a simple Gaussian observation model detailed in Section 6.2.

Our first lower bound underscores the need to make variance growth assumptions (4.9), in Theorem 4.3, for \( \text{Ind-Seq-LS} \) in the few trajectories \( (m \lesssim n) \) regime:

**Theorem 5.2** (Need for growth assumptions in \( \text{Ind-Seq-LS} \) when \( m \lesssim n \)). There exists universal constant \( c_0, c_1 \), and \( c_2 \) such that the following holds. Suppose that \( \mathcal{P}_x = \otimes_{t=1}^{\gamma} N(0, 2^t \cdot I_n) \), \( n \geq 6 \), \( mT \geq n \), and \( m \leq c_0 n \). Then:

\[
R(m, T, T'; \mathcal{P}_x) \geq c_1 \sigma_x^2 \cdot \frac{2c_2 n/m}{T}.
\]

Theorem 5.2 states that if the variances \( \Sigma_t \) are allowed to grow exponentially in \( t \), then the minimax risk of \( \text{Ind-Seq-LS} \) scales exponentially in \( n/m \) when \( m \lesssim n \). Thus, some sub-exponential growth assumption is necessary in order to have the risk scale polynomially in \( n/m \).

We now turn to a lower bound for \( \text{LDS-LS} \). We consider two particular hard instances for \( \text{LDS-LS} \) dynamics matrices \( (A, B) \), where we set \( B = I_n \) and vary \( A \). The first instance corresponds to iid covariates, i.e., \( A = 0_{n \times n} \). The second instance corresponds to an isotropic Gaussian random walk, i.e., \( A = I_n \). These two hard instances satisfy Assumption 4.1, Assumption 4.2, and Assumption 4.3. Together they show that our upper bounds are sharp up to logarithmic factors, treating the condition number \( \gamma(A, B) \) from Definition 4.4 as a constant:

**Theorem 5.3** (Risk lower bound). There are universal positive constants \( c_0, c_1 \), and \( c_2 \) such that the following holds. Recall that \( P_x^{I_n} \) (resp. \( P_x^{0_{n \times n}} \)) denotes the covariate distribution for a linear dynamical system with \( A = I_n \) and \( B = I_n \) (resp. \( A = 0_{n \times n} \) and \( B = I_n \)). If \( T \geq c_0, n \geq c_1 \), and \( mT \geq n \), then:

\[
R(m, T, T'; \{P_x^{0_{n \times n}}, P_x^{I_n}\}) \geq c_2 \sigma_x^2 \cdot \frac{p n}{mT} \cdot \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.
\]

We can interpret this lower bound by a breakdown of the quantity \( \phi := \max\{nT'/(mT), T'/T, 1\} \) across various regimes. When trajectories are limited \( (m \lesssim n) \), \( \phi \asymp \max\{nT'/(mT), 1\} \), and
therefore the minimax risk is bounded below by $\sigma^2 \cdot pn/(mT) \cdot \max\{nT'/(mT), 1\}$. This is the same rate prescribed by the OLS upper bound of Theorem 4.7, up to the condition number $\gamma(A, B)$ and logarithmic factors in $n/m$. We have thus justified the summary statement Theorem 1.2. On the other hand, under many trajectories ($m \gtrsim n$), $\phi \propto \max\{T'/T, 1\}$ and the minimax risk is bounded below by $\sigma^2 \cdot pn/(mT) \cdot \max\{T'/T, 1\}$. By Theorem 4.6, the OLS risk is bounded above by the same quantity times $\gamma(A, B)$, justifying the summary statement Theorem 1.3.

6 Key proof ideas

In this section, we highlight some of the key ideas behind our results. Proofs of the upper bounds are in Appendix B, and proofs of the lower bounds are in Appendix C.

Additional notation. For $r \in \mathbb{N}_+$ and $M \in \mathbb{R}^{n \times n}$, let $J_r \in \mathbb{R}^{r \times r}$ denote the Jordan block of size $r$ with ones along its diagonal, let $\text{BDiag}(M, r) \in \mathbb{R}^{nr \times nr}$ denote the block diagonal matrix with diagonal blocks $M$, and let $\text{BToep}(M, r) \in \mathbb{R}^{nr \times nr}$ denote the block Toeplitz matrix with first column $(I_n, M^T, \ldots, (M^{r-1})^T)^T$.

6.1 Upper bounds

The proof of Lemma 4.1 decomposes the risk using a standard basic inequality, which we now describe. While Lemma 4.1 is stated quite generally, for simplicity of exposition we restrict ourselves in this section to the case when the matrix parameters $\{\Psi_j\}_{j=1}^S$ in Definition 4.1 are all set to $\Gamma$. Under this simplification, we have that $\mu(\{\Psi_j\}_{j=1}^S, \Gamma) = 1$.

Equation (3.1) yields the identity $Y_{m,T} = X_{m,T}W_T + \Xi_{m,T}$. Plugging this relationship into the formula (3.6) for $\hat{W}_{m,T}$ gives $\hat{W}_{m,T} - W_s = \Xi_{m,T} \sum_{t=1}^T X_{m,T}(X_{m,T}^TX_{m,T})^{-1}$. Define the whitened version of $X_{m,T}$ as $\hat{X}_{m,T} := X_{m,T} \Gamma^{-1/2}$. From these definitions and after some basic manipulations, for any $\Gamma' \in \text{Sym}_{>0}^n$:

$$
||\hat{W}_{m,T} - W_s||_F^2 \leq \min\{n, p\} \frac{\xi_{m,T}}{\lambda_{\min}(\hat{X}_{m,T}^TX_{m,T}) \cdot \Lambda(\Gamma, \Gamma')}.
$$

(6.1)

This decomposes the analysis into two parts: (a) upper-bounding $||\hat{X}_{m,T}^T\hat{X}_{m,T}||_F^{-1} ||\hat{X}_{m,T}^T\Xi_{m,T}||_F^2$, which is a self-normalized martingale term, and (b) lower-bounding the term $\lambda_{\min}(\hat{X}_{m,T}^T\hat{X}_{m,T})$. The analysis for the martingale term is fairly standard (cf. Abbasi-Yadkori et al., 2011, Corollary 1), so for the remainder of this section we focus on the minimum eigenvalue bound, which contains much of what is novel in our analysis.

We first demonstrate how the trajectory small-ball definition (Definition 4.1) can be used to establish pointwise convergence of the quadratic form $\chi(v) := \sum_{i=1}^m \sum_{t=1}^T (v, \tilde{x}_t^{(i)})^2$ for $v \in \mathbb{S}^{n-1}$, where $\tilde{x}_t^{(i)} := \Gamma_{-1/2} \alpha_t^{(i)}$ is a whitened state vector. Specifically, we show that for a fixed $v \in \mathbb{S}^{n-1}$, the probability of the event $\{\chi(v) \leq \psi \cdot k\varepsilon\}$ is small, for positive constants $\psi, \varepsilon$ to be specified. Define the random indicator variables:

$$
B_{ij}^{(i)} := 1 \left\{ \sum_{t=(j-1)k+1}^{jk} (v, \tilde{x}_t^{(i)})^2 \geq k\varepsilon \right\}, \quad i = 1, \ldots, m, \quad j = 1, \ldots, S.
$$

22
Markov’s inequality yields the following lower bound:

\[
\sum_{i=1}^{m} \sum_{t=1}^{T} \langle v, \tilde{x}_t^{(i)} \rangle^2 \geq \sum_{i=1}^{m} \sum_{j=1}^{S} \sum_{t=(j-1)k+1}^{jk} \langle v, \tilde{x}_t^{(i)} \rangle^2 \geq k \varepsilon \sum_{i=1}^{m} \sum_{j=1}^{S} B_j^{(i)}.
\]

By a Chernoff bound and the independence of the trajectories \(\{\tilde{x}_t^{(i)}\}_{t \geq 1}\) and \(\{\tilde{x}_t^{(i')}\}_{t \geq 1}\) when \(i \neq i'\):

\[
P \left( \sum_{i=1}^{m} \sum_{t=1}^{T} \langle v, \tilde{x}_t^{(i)} \rangle^2 \leq \psi \cdot k \varepsilon \right) \leq P \left( \sum_{i=1}^{m} \sum_{j=1}^{S} B_j^{(i)} \leq \psi \right) \leq \inf_{\lambda \leq 0} e^{-\lambda \psi} \left[ \mathbb{E} \exp \left( \lambda \sum_{j=1}^{S} B_j^{(1)} \right) \right]^m.
\]

On the other hand, the trajectory small-ball condition (Definition 4.1) yields the lower bound:

\[
P(B_j^{(1)} = 1 \mid \mathcal{F}_{(j-1)k}) = \mathbb{P} \left( \sum_{t=(j-1)k+1}^{jk} \langle v, \tilde{x}_t^{(i)} \rangle^2 \geq k \varepsilon \mid \mathcal{F}_{(j-1)k} \right) \geq 1 - (c_{sb} \varepsilon)^\alpha \text{ a.s.}
\]

Now constrain \(\varepsilon \in (0, 1/c_{sb})\) so that \(c_1(\varepsilon) := 1 - (c_{sb} \varepsilon)^\alpha > 0\). This implies that, for \(\lambda \leq 0\):

\[
\mathbb{E} \left[ \exp \left( \lambda B_j^{(1)} \right) \mid \mathcal{F}_{(j-1)k} \right] = e^{\lambda \mathbb{P}(B_j^{(1)} = 1 \mid \mathcal{F}_{(j-1)k}) + \mathbb{P}(B_j^{(1)} = 0 \mid \mathcal{F}_{(j-1)k})}
\]

\[
= (e^{\lambda} - 1) \mathbb{P}(B_j^{(1)} = 1 \mid \mathcal{F}_{(j-1)k}) + 1
\]

\[
\leq c_1(\varepsilon)(e^{\lambda} - 1) + 1.
\]

The above inequality holds almost surely. By the tower property, we can inductively bound:

\[
\mathbb{E} \exp \left( \lambda \sum_{j=1}^{S-1} B_j^{(1)} \right) \leq \left( c_1(\varepsilon)(e^{\lambda} - 1) + 1 \right)^S.
\]

Choosing \(\psi = c_1(\varepsilon)mS/2\) and using the inequality \(1 + x \leq e^x\) valid for all \(x \in \mathbb{R}\),

\[
P \left( \sum_{i=1}^{m} \sum_{t=1}^{T} \langle v, \tilde{x}_t^{(i)} \rangle^2 \leq c_1(\varepsilon)mS/2 \cdot k \varepsilon \right) \leq \inf_{\lambda \leq 0} \exp \left( c_1(\varepsilon)mS \left[ -\frac{\lambda}{2} + e^\lambda - 1 \right] \right)
\]

\[
= \exp(-c_1(\varepsilon)(1 - \log 2)/2 \cdot mS).
\]

To upgrade (6.2) from pointwise to uniform over \(\mathbb{S}^{n-1}\), a natural approach is to use standard covering and union bound arguments. This, however, fails to yield the requisite upper bound on \(\mathbb{P}(\lambda_{\min}(\tilde{X}_{m,T}^T \tilde{X}_{m,T}) \leq t)\) that decays to zero as \(t \to 0\). Having control of the tail probability at all scales is needed in order to bound the expected value of (6.1) by integration. In order to circumvent this issue, in Lemma 4.1 we use the PAC-Bayes argument from Mourtada (2019) (which itself is an extension of Oliveira (2016)) to establish uniform concentration. While this argument itself is quite non-trivial, our adaptation of it is relatively straightforward. The details are given in Appendix B.4.
6.2 Lower bounds

6.2.1 Observation noise behind Lemma 5.1

Our definition of minimax risk $R(m, T, T'; P_x)$ in (3.5) involves a supremum over the worst case $\sigma_\xi$-sub-Gaussian MDS distribution that models the observation noise. The proof of Lemma 5.1 bounds this supremum from below by considering a noise model that decouples the observation noise $\{\xi_t\}_{t\geq 1}$ from the randomness that drives the trajectory $\{x_t\}_{t\geq 1}$:

**Definition 6.1** (Gaussian observation noise). The Gaussian observation noise model holds when $\xi_t \sim N(0, \sigma_\xi^2 I_p)$, $\xi_t \perp \xi_t$ if $t \neq t'$, and the process $\{\xi_t\}_{t\geq 1}$ is independent from the process $\{x_t\}_{t\geq 1}$.

Decoupling the noise processes orthogonalizes the two problems simultaneously present in Seq-LS: learning the dynamics of covariates and learning the responses from covariates. Definition 6.1 draws attention to the latter. It will unfortunately exclude us from addressing linear system identification specifically with our lower bound, but it allows a sharp and simple characterization of the minimax risk in general. The proof of Lemma 5.1 is given in Appendix C.2.

6.2.2 An analysis of non-isotropic gramian matrices

A key technical challenge for our analysis lies in constructing a sharp lower bound on the expected trace inverse of a gramian matrix formed by random non-isotropic Gaussian random vectors. Specifically, for integers $q, n \in \mathbb{N}_+$ with $q \geq n$, and for a fixed positive definite matrix $\Sigma \in \text{Sym}^q_{>0}$, we are interested in a lower bound on the quantity $\mathbb{E} \text{tr}((W^T \Sigma W)^{-1})$, where $W \in \mathbb{R}^{q \times n}$ has iid $N(0, 1)$ entries. The matrix $W^T \Sigma W$ is equal in distribution to the gramian matrix $Y \in \mathbb{R}^{n \times n}$ of the vectors $g_1, \ldots, g_n \in \mathbb{R}^q$, which are drawn iid from $N(0, \Sigma)$, i.e., $Y_{ij} = \langle g_i, g_j \rangle$.

The main tool we use to analyze $\mathbb{E} \text{tr}((W^T \Sigma W)^{-1})$ is the convex Gaussian min-max theorem (CGMT) from Thrampoulidis et al. (2014), which allows us to bound from below the expected trace inverse by studying a two-dimensional min-max game that is more amenable to analysis. The key idea is to cast the expected trace inverse as a least-norm optimization problem, and apply CGMT to the value of the optimization problem. We believe this result to be of independent interest.

**Lemma 6.1.** Let $q, n$ be positive integers with $q \geq n$ and $n \geq 2$. Let $W \in \mathbb{R}^{q \times n}$ have iid $N(0, 1)$ entries, and let $\Sigma \in \mathbb{R}^{q \times q}$ be positive definite. Let $g \sim N(0, I_q)$ and $h \sim N(0, I_{n-1})$, with $g$ and $h$ independent. Also, let $\{e_i\}_{i=1}^q$ be the standard basis vectors in $\mathbb{R}^q$. We have:

$$
\mathbb{E} \text{tr}((W^T \Sigma W)^{-1}) \geq \sum_{i=1}^q \mathbb{E} \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \|h\|^2}{\tau} + \|\beta g - e_i\|^2_{(\Sigma^{-1} + \beta \|h\|^2\tau I_q)^{-1}} \right]. 
$$

(6.3)

The proof of Lemma 6.1 appears in Appendix C.4. We now discuss how to analyze the two-dimensional min-max game appearing in Lemma 6.1. We first start by heuristically replacing it with a stylized problem, where the random quantities which appear in (6.3) are replaced by their expected scaling:

$$
\text{SP}(\Sigma, n) := \sum_{i=1}^q \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \sqrt{n}}{\tau} + \beta^2 \text{tr}((\Sigma^{-1} + \beta \sqrt{n} \tau I_q)^{-1}) + (\Sigma^{-1} + \beta \sqrt{n} \tau I_q)^{-1}_{ii} \right].
$$

(6.4)

\[= t_i(\beta, \tau)\]
While (6.4) is not a valid upper bound on the min-max game appearing in (6.3), analyzing (6.4) is simpler and gives the correct intuition; we give a rigorous upper bound in Lemma C.9.

We start by observing that if $\beta = 0$, then regardless of the choice of $\tau$, $\ell_i(0, \tau) = \Sigma_{ii}$, and therefore $\sum_{i=1}^q \ell_i(0, \tau) = \text{tr}(\Sigma)$ for any $\{\tau_i\}_{i=1}^q \subset \mathbb{R}_{>0}$. On the other hand, if $\beta > 0$, then $\ell_i(\beta, \tau)$ tends to $-\infty$ as $\tau \to 0^+$ and to $0$ as $\tau \to \infty$. Therefore, if we can show that there exists a $v \in (0, \text{tr}(\Sigma))$, such that every set of points $\{((\beta_i, \tau_i))\}_{i=1}^q \subset \mathbb{R}_{>0}^2$ satisfying:

$$\frac{\partial \ell_i}{\partial \beta}(\beta, \tau) = \frac{\partial \ell_i}{\partial \tau}(\beta, \tau) = 0, \quad i = 1, \ldots, q,$$

also satisfies $v = \sum_{i=1}^q \ell_i(\beta_i, \tau_i)$, then $\text{SP}(\Sigma, n) = v$.

To uncover the critical points, we define the functions $f$ and $q_i$, for $i = 1, \ldots, q$, as:

$$f(x) := -x\sqrt{n} + x^2 \text{tr}((\Sigma^{-1} + x\sqrt{n}I_q)^{-1}), \quad q_i(x) := (\Sigma^{-1} + x\sqrt{n}I_q)^{-1}_{ii}.$$

With these definitions, we can write:

$$\ell_i(\beta, \tau) = \frac{1}{\tau^2}f(\beta \tau) + q_i(\beta \tau).$$

Calculating $\frac{\partial f}{\partial \beta}(\beta, \tau) = \frac{\partial f}{\partial \tau}(\beta, \tau) = 0$ yields, for $\tau \neq 0$:

$$0 = \frac{\partial \ell_i}{\partial \tau}(\beta, \tau) = \tau^{-2}f'(\beta \tau)\beta - 2\tau^{-3}f(\beta \tau) + q_i'(\beta \tau)\beta,$$

$$0 = \frac{\partial \ell_i}{\partial \beta}(\beta, \tau) = \tau^{-2}f'(\beta \tau)\tau + q_i'(\beta \tau). \quad (6.5)$$

The second condition $6.6$ implies that $q_i'(\beta \tau) = -\tau^{-2}f'(\beta \tau)$. Plugging this condition into (6.5) implies that $f(\beta \tau) = 0$, and hence $\ell_i(\beta, \tau) = q_i(\beta \tau)$ for the critical point $(\beta, \tau)$. We now study the positive roots of the equation $f(x) = 0$, or equivalently:

$$x\sqrt{n} = x^2 \text{tr}((\Sigma^{-1} + x\sqrt{n}I_q)^{-1}).$$

Using the variable substitution $y := x\sqrt{n}$, we have, when $y > 0$, the equivalent problem:

$$\psi(y; \Sigma) := y \text{tr}((\Sigma^{-1} + yI_q)^{-1}) = n.$$

Observe that $\psi(0; \Sigma) = 0$ and $\lim_{y \to \infty} \psi(y; \Sigma) = q$. Furthermore, $\psi(y; \Sigma)$ is continuous and monotonically increasing with $y$. Therefore, as long as $q > n$, there is exactly one $y \in (0, \infty)$ such that $\psi(y; \Sigma) = n$, or equivalently there is exactly one $\bar{x} \in (0, \infty)$ such that $\psi(\bar{x}\sqrt{n}; \Sigma) = n$. Such a quantity $\bar{x}$ supplies the curve of critical points $\text{Crit}(\bar{x}) := \{((\beta, \tau) \in \mathbb{R}_{>0}^2 \mid \beta \tau = \bar{x}\}$. Note that $\text{Crit}(\bar{x})$ is the set of critical points for every $\ell_i(\beta, \tau)$, $i = 1, \ldots, q$. Furthermore, for any $(\beta_i, \tau_i) \in \text{Crit}(\bar{x})$ and $i \in \{1, \ldots, q\}$, we have that $\ell_i(\beta_i, \tau_i) = q_i(\beta_i, \tau_i) = (\Sigma^{-1} + \bar{x}\sqrt{n}I_q)^{-1}_{ii}$. Therefore:

$$\{((\beta_i, \tau_i))\}_{i=1}^q \subset \text{Crit}(\bar{x}) \implies \sum_{i=1}^q \ell_i(\beta_i, \tau_i) = \text{tr}((\Sigma^{-1} + \bar{x}\sqrt{n}I_q)^{-1}) \in (0, \text{tr}(\Sigma)),$$

and thus:

$$\text{SP}(\Sigma, n) = \sqrt{n} / \bar{x}, \quad \text{with } \bar{x} \text{ the solution to } \psi(\bar{x}\sqrt{n}; \Sigma) = n. \quad (6.7)$$
In light of (6.7), Lemma 6.1 then suggests that:

$$\mathbb{E} \text{tr}((W^T\Sigma W)^{-1}) \gtrapprox \frac{n}{\text{SP}(\Sigma, n)} = \bar{x}/n,$$

(6.8)

where the \(\gtrapprox\) notation indicates the heuristic nature of replacing the expected min-max game appearing in the bound (6.3) with the approximation (6.4).

If we briefly check (6.8) in the simple case when \(\Sigma = I_q\), we see that:

$$n = \psi(\bar{x}/n; I_q) = \bar{x}/n \frac{q}{1+\bar{x}/n} \implies \bar{x}/n = \frac{n}{q} (1 + \bar{x}/n) \gtrapprox \frac{n}{q}.$$

Hence, (6.8) yields that \(\mathbb{E} \text{tr}((W^T W)^{-1}) \gtrapprox n/q\), which is the correct scaling. The exact result is \(\mathbb{E} \text{tr}((W^T W)^{-1}) = n/(q - n - 1)\) for \(q \geq n + 2\).

### 6.2.3 Ideas behind Theorem 5.2

We let \(X_{m,T}\) denote the data matrix associated with \(m\) iid copies of \(\{x_t\}_{t=1}^T\), with \(x_t \sim N(0, 2^t \cdot I_n)\) and \(x_t \perp x_{t'}\) for \(t \neq t'\). We also define \(\Gamma_T := \frac{1}{T} \sum_{t=1}^T 2^t \cdot I_n = \frac{2}{T}(2^T - 1) \cdot I_n\), and observe that \(\Gamma_T \gtrapprox \frac{2^T}{T} \cdot I_n\). By Lemma 6.1, it suffices to lower bound the quantity \(\mathbb{E} \text{tr}(\Gamma_T^{1/2} (X_{m,T}^T X_{m,T})^{-1} \Gamma_T^{-1/2})\).

Since each column of \(X_{m,T}\) is independent, the matrix \(X_{m,T} 2^{-T/2}\) has the same distribution as \(\text{BDiag}(\Theta^{1/2}, m)\), where \(\Theta \in \mathbb{R}^{T \times T}\) is diagonal, \(\Theta_i = 2^{i-T}\) for \(i \in \{1, \ldots, T\}\), and \(W \in \mathbb{R}^{mT \times n}\) has iid \(N(0, 1)\) entries. In other words, we have:

$$\mathbb{E} \text{tr}(\Gamma_T^{1/2} (X_{m,T}^T X_{m,T})^{-1} \Gamma_T^{-1/2}) \gtrapprox \frac{1}{T} \mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta, m) W)^{-1}).$$

By the arguments in Section 6.2.2, we have:

$$\mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta, m) W)^{-1}) \gtrapprox \frac{n}{\text{SP}(\text{BDiag}(\Theta, m), n)},$$

where the notation \(\gtrapprox\) indicates the heuristic nature of the inequality as explained previously. From (6.7), we want to find \(\bar{x}\) such that:

$$n = \psi(\bar{x}/n; \text{BDiag}(\Theta, m)) = \bar{x}/n \cdot m \sum_{j=0}^{T-1} \frac{1}{2^j + \bar{x}/n}.$$

While solving this equation exactly for \(\bar{x}/n\) is not tractable, we can estimate a lower bound on \(\bar{x}/n\) quite easily. For any integer \(T_c \in \{0, \ldots, T\}\), we have the following estimate:

$$\frac{n}{m} = \bar{x}/n \sum_{j=0}^{T-1} \frac{1}{2^j + \bar{x}/n} \leq T_c + 2\bar{x}/n \cdot 2^{-T_c}.$$

Let us first assume that \(\bar{x}/n \in [1, 2^{T-1}]\), so that \([\log_2(\bar{x}/n)] \in \{0, \ldots, T\}\). Setting \(T_c = [\log_2(\bar{x}/n)]\) then yields the lower bound \(\bar{x}/n \gtrapprox 2^{n/m-3}\). On the other hand, if \(\bar{x}/n > 2^{T-1}\), then since we assume \(mT \geq c_1 n\), we also have \(\bar{x}/n \gtrapprox 2^{n/m-1}\). Finally, if \(\bar{x}/n < 1\), we have:

$$\frac{n}{m} = \bar{x}/n \sum_{j=0}^{T-1} \frac{1}{2^j + \bar{x}/n} < T_{\text{SP}} \frac{1}{2^j + \bar{x}/n} \leq 2 \implies m \geq n/2.$$
This yields a contradiction, since by assumption \( m \leq c_2 n \), if \( c_2 < 1/2 \), so we must have \( \bar{x} \sqrt{n} \geq 2e'^n/m^3 \) with \( e' = \min\{1, c_1\} \). Now by (6.7) and (6.8):

\[
\text{SP}(B\text{Diag}(\Theta, m), n) = \frac{n}{\bar{x} \sqrt{n}} \leq n 2^{-e'^n/m^3} \Rightarrow \mathbb{E} \text{tr}(\Gamma^{1/2}_T (X_{m,T}^T X_{m,T})^{-1} \Gamma^{-1/2}_T) \gtrsim \frac{2e'^n/m}{T}.
\]

We make this argument rigorous in Appendix C.5.

6.2.4 Ideas behind Theorem 5.3

We focus here on the hard instance when \( A = I_n \) and \( m \lesssim n \), since the cases when \( A = 0_{n \times n} \) or \( A = I_n \) and \( m \gtrsim n \) are straightforward applications of Jensen’s inequality and some basic manipulations (see Lemma C.7).

The proof used by Theorem 5.3 when \( A = I_n \) and \( m \lesssim n \) is actually a special case of a general proof indexed by the largest Jordan block size of the hard instance. For a maximum Jordan block size \( r \), the hard instances are \( A = B\text{Diag}(J_r, n/r) \), where we assume for simplicity that \( r \) divides \( n \); this reduces to \( A = I_n \) when \( r = 1 \). We associate two important matrices with these hard instances. To define them, let \( I_r := \{1, 1+r, \ldots, 1+(T-1)r\} \), and let \( E_{I_r} \in \mathbb{R}^{T \times Tr} \) denote the linear operator that extracts the coordinates in \( I_r \). The following matrices then play a key role in our analysis:

\[
\Psi_{r,T,T'} := B\text{Diag}(\Gamma^{-1/2}_T(J_r), T)B\text{Toep}(J_r, T), \quad \Theta_{r,T,T'} := E_{I_r} \Psi_{r,T,T'} \Psi_{r,T,T'}^{T} E_{I_r}^{T}.
\]

The next step is to use a simple decoupling argument (see Lemma C.10) to argue that, for \( A = B\text{Diag}(J_r, d) \):

\[
\mathbb{E} \text{tr}(\Gamma^{1/2}_T (X_{m,T}^T X_{m,T})^{-1} \Gamma^{-1/2}_T) \geq \mathbb{E} \text{tr}((W^T B\text{Diag}(\Theta_{r,T,T'}, m)W)^{-1}),
\]

where \( W \in \mathbb{R}^{mT \times d} \) has iid \( N(0,1) \) entries. This positions us to use the arguments in Section 6.2.2 again. We first focus on the \( r = 1 \) case. We reduce the problem to assuming \( T' = T \), by observing that since \( \Gamma_t(I_n) = t+1 \cdot I_n \) for any \( t \in \mathbb{N}_+ \), then \( \Theta_{1,T,T'} = T_{T+1}^{T+1} \cdot \Theta_{1,T,T} \). Therefore,

\[
\mathbb{E} \text{tr}((W^T B\text{Diag}(\Theta_{1,T,T'}, m)W)^{-1}) = \frac{T' + 1}{T + 1} \cdot \mathbb{E} \text{tr}((W^T B\text{Diag}(\Theta_{1,T,T}, m)W)^{-1}) \geq \frac{n}{T + 1} \cdot \text{SP}(B\text{Diag}(\Theta_{1,T,T}, m), n),
\]

where again the \( \gtrsim \) notation highlights the heuristic nature of the bound, used to build intuition.

To proceed, let \( L_T \in \mathbb{R}^{T \times T} \) be the lower triangular matrix of all ones and define \( S_T := (L_T L_T^T)^{-1} \). A computation yields that \( \Theta_{1,T,T}^{-1} = T_{T+1}^{T+1} S_T \). Note that we can write \( S_T \) as a rank-one perturbation to a tri-diagonal matrix. Specifically, \( S_T = \text{Tri}(2,-1;T) - e_{T+1} e_{T+1}^T \), where \( \text{Tri}(a,b;T) \) denotes the symmetric \( T \times T \) tri-diagonal matrix with \( a \) on the diagonal and \( b \) on the lower and upper off-diagonals. By the standard formula for the eigenvalues of a tri-diagonal matrix, we have that \( \lambda_{T-k+1}(\text{Tri}(2,-1;T)) = 2 \left(1 - \cos \left( \frac{kr}{T+1} \right) \right) \approx k^2/T^2 \). In Appendix C.7, we apply the work of Kulkarni et al. (1999) to show that the rank-one perturbation is negligible: \( \lambda_{T-k+1}(S_T) \approx k^2/T^2 \).
\[ T_d \left( \frac{p}{2m} \right) \sim c_r \cdot \frac{d}{m} \cdot \frac{1}{T}. \]  

This implies that \( \psi_x \gtrsim n^2 / (m^2 T) \), and therefore by (6.7) and (6.8):

\[
\text{SP}(\text{BDiag}(\Theta_{1,T,T},m), n) = \frac{n}{\bar{x} \sqrt{n}} \leq \frac{m^2 T}{n} \implies \mathbb{E} \text{tr}(\Gamma_{1,T,T}^{-1/2}(X_{m,T}^TX_{m,T})^{-1}\Gamma_{T,T}^{-1/2}) \gtrsim \frac{T'}{T} \cdot \frac{n^2}{m^2 T}.
\]

We make this argument rigorous in Appendix C.8.

### 6.2.5 Beyond diagonalizability

When \( r \geq 2 \), the analytic complexity of characterizing the solution to \( n = \psi(\bar{x} \sqrt{n}; \text{BDiag}(\Theta_{r,T,T'},m)) \) increases significantly. Nevertheless, we can still solve for \( \bar{x} \sqrt{n} \) by numerical root finding, to look at the scaling patterns for small values of \( r \) and \( T' = T \). This computation (Figure 2) leads us to conjecture a general bound of \( \mathcal{R}(m, T, T'; \{ \text{BDiag}(J,T,n/r) \}) \gtrsim c_r n^{2r} / (m^{2r} T) \) when \( m \lesssim n \), where \( c_r \) is a constant depending only on \( r \). A complete and precise statement is given in Appendix A.

### 7 Concluding remarks

Having sharply characterized the worst-case excess risk of \text{Seq-LS} and \text{LDS-LS}, we see more precisely the trade-offs—or arguably the lack thereof—presented by resetting a system, or by simply observing parallel runs from one, where possible. After sufficient resets, one learns roughly as though examples were independent altogether (as reflected in the \text{Ind-Seq-LS} and \text{Ind-LDS-LS} baselines).
In addition to the theoretical upshot that it presents, this phenomenon seems encouraging insofar as the setup may describe reality: one does not learn to ride a bicycle by witnessing thousands of unrelated pedal strokes, nor by watching one cyclist endure the entire Tour de France, but rather by seeing and attempting many moderate rides and maneuvers.

We see a number of future directions for research, primarily in further charting out the reach of the iid-like phenomenon in learning from multiple sequences. Our work offers the trajectory small-ball criterion (Definition 4.1) as a vehicle for proving that this phenomenon occurs, or otherwise for bounding the minimax rate from above. What other notable sequential processes, outside of those covered in Section 4.1, can we capture as trajectory small-ball instances? One might look to covariate sequences generated by, say, input-to-state stable (ISS) non-linear systems, stochastic polynomial difference equations, or various Markov decision processes.

On the flip side, when must we necessarily pay a price for dependent data? One answer from our work is that a necessary gap between independent and sequentially dependent learning appears when there are insufficiently many trajectories \( m \lesssim n \). As outlined in Section 6.2.5 and Appendix A, we conjecture that this gap can be made much wider, namely by considering non-diagonalizable linear dynamical systems. That said, other pertinent problems may exhibit gaps as well. Finding them would help inform where the limits of learning from sequential data lie.

On the regression side, one might look to move beyond a well-specified linear regression model, extend to other loss functions, analyze regularized least-squares estimators in place of OLS, or consider a more adversarial analysis (e.g. measuring regret rather than risk, in an online setting).

Acknowledgements

We thank Vikas Sindhwani for organizing a lecture series on learning and control, during which this work was prompted, and for encouraging us to pursue the ensuing questions. We also thank Juan C. Perdomo for inspiring the proof of Proposition B.9. M. A Beyond diagonalizability: a conjecture for the general case

Recall that various results in Section 4.2 required a diagonalizability assumption (Assumption 4.2) on the dynamics matrix $A$, specifically in the many trajectories regime when $T' > T$ (Theorem 4.6), or in the few trajectories regime (Section 4.2.2). In this section, we conjecture how removing the diagonalizability assumption would affect the results. For simplicity, we focus on the few trajectories regime, and further assume that $T' = T$. Building on potential extensions of this paper’s analysis, and numerical evidence detailed in Section 6, we conjecture the following extensions of Theorem 4.7 and Theorem 5.3:

**Conjecture A.1** (Risk for LDS-LS with few trajectories under non-diagonalizable systems). There are universal positive constants $c_0$, $c_1$, $c_2$, $c_3$, and a universal mapping $\varphi : \mathbb{N}_+ \to \mathbb{R}_{>0}$ such that the following holds for any instance of LDS-LS satisfying Assumption 4.1 (marginal stability) and Assumption 4.3 (one-step controllability). Let $A = SJS^{-1}$ denote the Jordan normal form of the dynamics matrix $A$. Define $\gamma := \frac{\lambda_{\max}(S^{-1}BB^TS^{-1})}{\lambda_{\min}(S^{-1}BB^TS^{-1})}$, and let $r$ be the size of the largest Jordan block in $J$. If $n \geq c_0$, $m \leq c_1 n$, and $mT \geq c_2 n$, then:

$$\mathbb{E}[L(\hat{W}_{m,T}; T', P^A_{x})] \leq c_3 \sigma_2^2 \varphi(r) \frac{pn^{2r}}{m^{2r}T}. \quad (A.1)$$

Additionally, there exist universal positive constants $c'_0$, $c'_1$, $c'_2$, $c'_3$, and $c'_4$ such that the following is true. Suppose $A \subseteq \mathbb{R}^{n \times n}$ is any set containing all $n \times n$ matrices with Jordan blocks of size at most $r$. Let $T \geq c'_0$, $n \geq c'_1$, $mT \geq c'_2 n$, and $m \leq c'_3 n$. Then:

$$R(m, T, T; \{P^A_x \mid A \in A\}) \geq c'_4 \sigma_2^2 \varphi(r) \gamma \cdot \frac{pn^{2r}}{m^{2r}T}. \quad (A.2)$$

Lemma 4.1 provides a viable path towards proving the upper bound (A.1) from Conjecture A.1 up to logarithmic factors in the regime of constant Jordan block size $r$, by reducing the problem to understanding the scaling of $\lambda(k; t; A, B) = \lambda(\Gamma_k(A, B), \Gamma_t(A, B))$ when $k \leq t$. Our analysis uses diagonalizability (Assumption 4.2) of the dynamics matrices to show that $\lambda(k; t; A, B) \geq \gamma^{-1} \cdot k/t$. Without such an assumption, analyzing $\lambda(k; t; A, B)$ is substantially more involved. A numerical simulation (Figure 3) suggests that $\lambda(k; t; A, B) \geq c_r \gamma^{-1} \cdot (k/t)^{2r-1}$ is the general rate for dynamics matrices $A$ with Jordan blocks at most size $r$, where $c_r$ is a constant depending only on $r$. Assuming this scaling to be correct and plugging the rate into Lemma 4.1 yields (A.1) up to logarithmic factors. Partial progress towards analyzing $\lambda(k; t; A, B)$ was made in Sarkar and Rakhlin (2019, Proposition 7.6), where it is shown that $\lambda(k; t; A, B) \geq c_r \gamma^{-1} \cdot (k/t)^2$, with $1/c_r$ depending exponentially on $r$. We do not conjecture a form for the mapping $\varphi(r)$; $\lambda(k; t; A, B)$ becomes numerically ill-conditioned when $r$ is large, hindering simulation with large blocks.

On the other hand, the analytic arguments in Section 6.2.4 combined with the numerical evidence in Figure 2 suggest that the bound (A.2) holds (up to the condition number factor $\gamma$). The one caveat is that, even if we were to analytically characterize the eigenvalues of $\Theta_{r,T,T}$ for all $r$, our proof strategy would most likely not be able to give a sharp characterization of the leading constant $\varphi(r)$ in the lower bound. This is because our proof inherently exploits the independence between decoupled subsystems, and does not tackle the harder challenge of understanding the coupling effects within a Jordan block.

We conclude this section by noting that Conjecture A.1 does not include any logarithmic factors in the upper bound rate (A.1), and includes the condition number factor $\gamma$ in the lower bound (A.2).
Figure 3: A plot of the ratio $\alpha$ versus $1/\lambda(k, t)$ with $k$ fixed to 5 and $t$ fixed to $k\alpha$. Here, $\lambda(k, t) := \lambda(k, t; J_r, I_r)$. The slope of the line (in log-log space) computed via linear regression is reported. We conjecture that in general, $\lambda(k, t; A, B) \gtrsim c_r \gamma^{-1} \cdot (k/t)^{2r-1}$.

In other words, Conjecture A.1 applied to the special case of $r = 1$ conjectures that Theorem 4.7 is loose by $\log^2(\gamma n/m)$, and that Theorem 5.3 is loose by a factor of $\gamma$.

B Analysis for upper bounds

B.1 Preliminaries

In this section, we collect various technical results which we will use in the proof of the upper bounds. Our first claim is an elementary observation which we will use repeatedly in the sequel.

**Proposition B.1.** Let $T \geq 1$ and let $k \in [1, T]$. We have that:

$$\left\lfloor \frac{T}{k} \right\rfloor \leq \frac{T}{k} \leq 2 \left\lfloor \frac{T}{k} \right\rfloor.

Proof.** The lower bound is immediate. For the upper bound, write:

$$T = \lceil T/k \rceil k + r, \quad r \in [0, k].$$

But this means that:

$$\frac{T}{k} = \lceil T/k \rceil + \frac{r}{k} \leq \lceil T/k \rceil + 1 \leq 2\lceil T/k \rceil,$$

where the last inequality holds since $\lceil T/k \rceil \geq 1$. \hfill \Box

Next, we state a result which gives us a bound on the functional inverse of $T \mapsto T/\log T$.

**Proposition B.2** (Simchowitz et al. (2018, Lemma A.4)). Let $\alpha \geq 1$. Then, $T \geq 2\alpha \log(4\alpha)$ implies that $T \geq \alpha \log T$.  

37
The next two results study various properties of functions involving $\lambda$.

**Proposition B.3.** Fix any $A \in \text{Sym}^n_{>0}$. The map $X \mapsto \lambda(X, A)$ is concave over symmetric matrices in $\mathbb{R}^{n \times n}$.

**Proof.** Observe that $\lambda(X, A) = \lambda_{\min}(A^{-1/2}XA^{-1/2}) = \inf \{\langle X, A^{-1/2}vv^T A^{-1/2} \rangle \mid v \in S^{n-1} \}$ is the pointwise infimum over a set of linear functions, and is therefore concave.

**Proposition B.4.** Fix $T \in \mathbb{N}_+$, $\{\Psi_t\}_{t=1}^T \subset \text{Sym}^n_{>0}$, and $\Gamma \in \text{Sym}^n_{>0}$. Suppose that $\frac{1}{T} \sum_{t=1}^T \Psi_t \preccurlyeq \Gamma$.

Then:

$$\left[ \prod_{t=1}^T \lambda(\Psi_t, \Gamma) \right]^{1/T} \leq 1.$$

**Proof.** We have that:

$$\left[ \prod_{t=1}^T \lambda(\Psi_t, \Gamma) \right]^{1/T} \leq \frac{1}{T} \sum_{t=1}^T \lambda(\Psi_t, \Gamma) \quad \text{using the AM-GM inequality}$$

$$\leq \lambda \left( \frac{1}{T} \sum_{t=1}^T \Psi_t, \Gamma \right) \quad \text{using Proposition B.3 and Jensen’s inequality}$$

$$\leq \lambda(\Gamma, \Gamma) \quad \text{since } \frac{1}{T} \sum_{t=1}^T \Psi_t \preccurlyeq \Gamma$$

$$= 1.$$

The next result relates the anti-concentration properties of a non-negative random variable to its moment generating function on $(-\infty, 0)$.

**Proposition B.5** (Mourtada (2019, Lemma 7)). Let $X$ be a non-negative random variable. Suppose there exists an $\alpha \in (0, 1]$ and positive constant $c$ such that:

$$\mathbb{P}(X \leq t) \leq (ct)^\alpha \quad \forall t > 0.$$

Then:

$$\mathbb{E}[\exp(-\eta X)] \leq (c/\eta)^\alpha \quad \forall \eta > 0.$$

The next few results involve various properties of quadratic and quartic Gaussian polynomials.

**Proposition B.6** (Magnus (1978, Lemma 6.2)). For $w \sim N(0, I_n)$ and symmetric matrices $A, B \in \mathbb{R}^{n \times n}$:

$$\mathbb{E}[w^T Aww^T Bw] = 2\langle A, B \rangle + \text{tr}(A) \text{tr}(B).$$
Lemma B.7. Let \( x \in \mathbb{R}^d \) be fixed, \( w \sim N(0, I_q) \), and let \( Q = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \) be positive semidefinite, with \( Q_{11} \in \mathbb{R}^{d \times d} \), \( Q_{12} \in \mathbb{R}^{d \times q} \), and \( Q_{22} \in \mathbb{R}^{q \times q} \). For any \( \lambda > 0 \), we have:

\[
\mathbb{E} \exp \left( -\lambda \begin{bmatrix} x \\ w \end{bmatrix}^T \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \right) \leq \det(I_q + 2\lambda Q_{22})^{-1/2}.
\]

Proof. Define \( \mu := -(Q_{22} + (2\lambda)^{-1}I_q)^{-1/2}Q_{12}^T x \). We have:

\[
\mathbb{E} \exp \left( -\lambda \begin{bmatrix} x \\ w \end{bmatrix}^T \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \right) \\
= (2\pi)^{-q/2} \int \exp \left\{ -\lambda \left[ x^T Q_{11} x + 2x^T Q_{12} w + w^T (Q_{22} + (2\lambda)^{-1}I_q) w + \mu^T \mu - \mu^T \mu \right] \right\} \, dw \\
= (2\pi)^{-q/2} \int \exp \left\{ -\lambda \left[ x^T Q_{11} x - \|\mu\|^2_2 + \|Q_{22} + (2\lambda)^{-1}I_q\|^{1/2} x - \|\mu\|^2_2 \right] \right\} \, dw \\
= (2\pi)^{-q/2} \exp \left\{ -\lambda \|Q_{22} + (2\lambda)^{-1}I_q\|^{1/2} x - \|\mu\|^2_2 \right\} \int \exp \left\{ -\lambda \|Q_{22} + (2\lambda)^{-1}I_q\|^{1/2} x - \|\mu\|^2_2 \right\} \, dw \\
= \det(I_q + 2\lambda Q_{22})^{-1/2} \exp \left\{ -\lambda x^T [Q_{11} - Q_{12} (Q_{22} + (2\lambda)^{-1}I_q)^{-1} Q_{12}^T] x \right\}.
\]

Next, observe that the matrix \( Q_{11} - Q_{12} (Q_{22} + (2\lambda)^{-1}I_q)^{-1} Q_{12}^T \) is positive semidefinite, since it is the Schur complement of the positive semidefinite matrix:

\[
\begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & (2\lambda)^{-1}I_q \end{bmatrix}
\]

Therefore:

\[
\exp \left\{ -\lambda x^T [Q_{11} - Q_{12} (Q_{22} + (2\lambda)^{-1}I_q)^{-1} Q_{12}^T] x \right\} \leq 1.
\]

\[\square\]

Lemma B.8. Suppose the hypothesis of Lemma B.7 hold. For any \( \varepsilon > 0 \),

\[
P \left\{ \begin{bmatrix} x \\ w \end{bmatrix}^T \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \leq \varepsilon \cdot \text{tr}(Q_{22}) \right\} \leq (\varepsilon \varepsilon)^{1/2}.
\]

Proof. Let \( \{\lambda_i\}_{i=1}^q \) denote the eigenvalues of \( Q_{22} \). We observe that for any \( \eta > 0 \), since all the eigenvalues of \( Q_{22} \) are non-negative:

\[
\det(I_q + 2\eta Q_{22}) = \prod_{i=1}^q (1 + 2\eta \lambda_i) \geq 1 + 2\eta \sum_{i=1}^q \lambda_i = 1 + 2\eta \text{tr}(Q_{22}).
\]

39
Now by a Chernoff bound:

\[
\mathbb{P}\left\{ \begin{bmatrix} x \\ w \end{bmatrix}^T \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \leq \varepsilon \cdot \text{tr}(Q_{22}) \right\} \\
\leq \inf_{\eta > 0} \exp\{\eta \varepsilon \text{tr}(Q_{22})\} \mathbb{E} \exp\left( -\eta \begin{bmatrix} x \\ w \end{bmatrix}^T \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^T & Q_{22} \end{bmatrix} \begin{bmatrix} x \\ w \end{bmatrix} \right) \\
\leq \inf_{\eta > 0} \exp\{\eta \varepsilon \text{tr}(Q_{22})\} \det(I_q + 2\eta Q_{22})^{-1/2} \quad \text{using Lemma B.7} \\
\leq \inf_{\eta > 0} \exp\{\eta \varepsilon \text{tr}(Q_{22})\} (1 + 2\eta \text{tr}(Q_{22}))^{-1/2} \\
\leq (\varepsilon^{1-\varepsilon})^{1/2} \quad \text{setting } \eta = (1 - \varepsilon)/(2\varepsilon \text{tr}(Q_{22})) \\
\leq (\varepsilon \varepsilon)^{1/2}.
\]

The following result gives rise to anti-concentration of a random vector chosen uniformly on the sphere. A similar bound appears in Dasgupta and Gupta (2003, Lemma 2.2).

**Proposition B.9.** Let \( n \geq 2 \) and \( v \in \mathbb{R}^n \setminus \{0\} \) be fixed. Suppose that \( \psi \) is drawn uniformly at random from the uniform measure over \( S^{n-1} \). We have that for all \( \varepsilon > 0 \):

\[
\mathbb{P}\left\{ \langle v, \psi \rangle^2 \leq \frac{\varepsilon}{n} \|v\|^2 \right\} \leq (\varepsilon \varepsilon)^{1/2}.
\]

**Proof.** Since \( v \neq 0 \), we may assume wlog that \( \|v\|_2 = 1 \). Next, since the distribution of \( \psi \) is rotationally invariant, we can actually assume wlog that \( v = e_1 \). Furthermore, if \( \varepsilon \geq 1/e \), then there is nothing to prove, so we assume \( \varepsilon \in (0, 1/e) \).

The quantity \( \langle e_1, \psi \rangle^2 \) is equal in distribution to the quantity:

\[
\frac{g_i^2}{\sum_{i=1}^n g_i^2}, \quad g \sim N(0, I_n).
\]

Therefore:

\[
\mathbb{P}\left\{ \langle e_1, \psi \rangle^2 \leq \frac{\varepsilon}{n} \right\} = \mathbb{P}\left\{ \frac{\sum_{i=1}^n g_i^2}{\sum_{i=1}^n g_i^2} \leq \frac{\varepsilon}{n} \right\} \\
= \mathbb{P}\left\{ g_1^2 \leq \frac{\varepsilon}{n-\varepsilon} \sum_{i=2}^n g_i^2 \right\} \quad \text{since } 1 - \varepsilon/n > 0 \\
= \mathbb{E}_{g_2:n} \mathbb{P}\left\{ g_1^2 \leq \frac{\varepsilon}{n-\varepsilon} \sum_{i=2}^n g_i^2 \right\} \left\| g_{2:n} \right\| \\
\leq \mathbb{E}_{g_2:n} \left( \frac{\varepsilon}{n-\varepsilon} \sum_{i=2}^n g_i^2 \right)^{1/2} \quad \text{using Lemma B.8} \\
\leq \left( \frac{\varepsilon}{n-\varepsilon} (n-1) \right)^{1/2} \quad \text{using Jensen’s inequality} \\
\leq (\varepsilon \varepsilon)^{1/2} \quad \text{since } \varepsilon \in (0, 1/e).
\]

\(\square\)
Next, a classic result which gives us anti-concentration of arbitrary Gaussian (more generally any log-concave distribution) polynomials of bounded degree.

**Theorem B.10** (Carbery and Wright (2001, Theorem 8)). Fix an integer $d \in \mathbb{N}_+$. There exists a universal positive constant $c$ such that the following is true. Let $p : \mathbb{R}^n \rightarrow \mathbb{R}$ be a degree $d$ polynomial, and let $\varepsilon > 0$. We have:

$$\mathbb{P}\{|p(x)| \leq \varepsilon \mathbb{E}|p(x)|\} \leq c \cdot d \varepsilon^{1/d}, \quad x \sim N(0, I_n).$$

Next, we state a well-known result from Abbasi-Yadkori et al. (2011), which yields an anytime bound for the size of a self-normalized martingale difference sequence (MDS).

**Lemma B.11** (Abbasi-Yadkori et al. (2011, Theorem 3)). Fix a $\delta \in (0, 1)$ and positive definite matrix $V \in \mathbb{R}^{d \times d}$. Let $\{x_t\}_{t \geq 1} \subset \mathbb{R}^d$ be a stochastic process adapted to the filtration $\{\mathcal{F}_t\}_{t \geq 1}$. Let $\{\eta_t\}_{t \geq 1} \subset \mathbb{R}$ be a martingale difference sequence adapted to $\{\mathcal{F}_t\}_{t \geq 2}$. Suppose there exists $R > 0$ such that $\mathbb{E}[\exp(\lambda \eta_t) | \mathcal{F}_t] \leq \exp(\lambda^2 R^2 / 2)$ a.s. for all $\lambda \in \mathbb{R}$ and $t \geq 1$. Define $V_t := \sum_{k=1}^t x_k x_k^T$ for $t \geq 1$. With probability at least $1 - \delta$,

$$\left\| \sum_{k=1}^t \eta_k x_k \right\|_{(V_t + V)^{-1}} \leq 2R^2 \log \left( \frac{\det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right) \quad \forall t \geq 1.$$

We now generalize this result to a vector-valued self-normalized MDS, following Sarkar and Rakhlin (2019).

**Proposition B.12** (Sarkar and Rakhlin (2019, Proposition 8.2)). Fix a $\delta \in (0, 1)$ and positive definite matrix $V \in \mathbb{R}^{p \times d}$. Let $\{x_t\}_{t \geq 1} \subset \mathbb{R}^d$ be a stochastic process adapted to the filtration $\{\mathcal{F}_t\}_{t \geq 1}$. Let $\{\eta_t\}_{t \geq 1} \subset \mathbb{R}^p$ be a stochastic process adapted to $\{\mathcal{F}_t\}_{t \geq 2}$. Suppose that for every fixed $v \in \mathbb{S}^{p-1}$, for every $t \geq 1$:

(i) $\mathbb{E}[\langle v, \eta_t \rangle | \mathcal{F}_t] = 0$ a.s.

(ii) $\mathbb{E}[\exp(\lambda \langle v, \eta_t \rangle) | \mathcal{F}_t] \leq \exp(\lambda^2 R^2 / 2)$ a.s. for every $\lambda \in \mathbb{R}$.

Define $V_t := \sum_{k=1}^t x_k x_k^T$ for $t \geq 1$. With probability at least $1 - \delta$, for all $t \geq 1$:

$$\left\| \sum_{k=1}^t \eta_k x_k^T (V_t + V)^{-1/2} \right\|_{op} \leq 2 \sqrt{R^2 \log \left( \frac{\det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right)}.$$

**Proof.** Fix a unit $v \in \mathbb{S}^{p-1}$. By Lemma B.11, with probability at least $1 - \delta$, for all $t \geq 1$:

$$\left\| (V_t + V)^{-1/2} \sum_{k=1}^t x_k \langle v, \eta_k \rangle \right\|_2 \leq \sqrt{R^2 \log \left( \frac{\det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right)}.$$

Let $N_p(1/2)$ be a $1/2$-net of $\mathbb{S}^{p-1}$. By a standard volume comparison argument, $|N_p(1/2)| \leq 5^p$. Hence, with probability at least $1 - \delta$, for all $t \geq 1$:

$$\max_{v_i \in N_p(1/2)} \left\| (V_t + V)^{-1/2} \sum_{k=1}^t x_k \langle v_i, \eta_k \rangle \right\|_2 \leq \sqrt{R^2 \log \left( \frac{5^p \det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right)}.$$
The claim now follows since:
\[
\left\| \sum_{k=1}^{t} \eta_k x_k^T (V_t + V)^{-1/2} \right\|_{op} = \sup_{v \in S^{n-1}} \left\| (V_t + V)^{-1/2} \sum_{k=1}^{t} x_k \langle v, \eta_k \rangle \right\|_2 \\
\leq 2 \max_{v \in \mathbb{S}^{(1/2)}} \left\| (V_t + V)^{-1/2} \sum_{k=1}^{t} x_k \langle v, \eta_k \rangle \right\|_2.
\]

The next result assumes \( V_t \) is invertible in order to simplify Proposition B.12.

**Proposition B.13.** Under the same hypothesis of Proposition B.12, we have with probability at least \( 1 - \delta \), for all \( t \geq 1 \):
\[
\mathbb{I}\{V_t \succeq V\} \left\| \sum_{k=1}^{t} \eta_k x_k^T V_t^{-1/2} \right\|_{op} \leq 4 \cdot \mathbb{I}\{V_t \succeq V\} \sqrt{R^2 \log \left( \frac{5p \det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right)}.
\]

**Proof.** Observe that when \( V_t \succeq V \), we have:
\[
2V_t = V_t + V_t \succeq V_t + V \implies V_t^{-1} \preceq 2(V_t + V)^{-1}.
\]

For two positive definite matrices \( M_1 \) and \( M_2 \) satisfying \( M_1 \preceq M_2 \), and any matrix \( N \),
\[
\|NM_1^{1/2}\|_{op} = \sqrt{\lambda_{\text{max}}(NM_1N^T)} \leq \sqrt{\lambda_{\text{max}}(NM_2N^T)} = \|NM_2^{1/2}\|_{op}.
\]

Therefore,
\[
\mathbb{I}\{V_t \succeq V\} \left\| \sum_{k=1}^{t} \eta_k x_k^T V_t^{-1/2} \right\|_{op} \leq 2 \cdot \mathbb{I}\{V_t \succeq V\} \left\| \sum_{k=1}^{t} \eta_k x_k^T (V_t + V)^{-1/2} \right\|_{op} \\
\leq 4 \cdot \mathbb{I}\{V_t \succeq V\} \sqrt{R^2 \log \left( \frac{5p \det(V_t + V)^{1/2} \det(V)^{-1/2}}{\delta} \right)},
\]

where the last inequality holds for every \( t \) with probability at least \( 1 - \delta \) by Proposition B.12. \( \square \)

### B.2 Examples of trajectory small-ball

In this section, we prove that the examples listed in Section 4.1 satisfying the trajectory small-ball condition (Definition 4.1).

**Example 4.1** (Copies of a Gaussian draw). Let \( \Sigma \in \text{Sym}_n^{>0} \), and let \( P_x \) denote the process \( x_1 \sim N(0, \Sigma) \) and \( x_t = x_{t-1} \) for \( t \geq 2 \). Fix any \( T \in \mathbb{N}_+ \). Then \( P_x \) satisfies the \( (T, T, \Sigma, e, \frac{1}{2}) \)-TrajSB condition.

**Proof.** When \( k = T \) and \( \Gamma = I_n \), the condition (4.1) simplifies to:
\[
\sup_{v \in S^{n-1}} \mathbb{P} \left\{ \frac{1}{T} \sum_{t=1}^{T} \langle v, x_t \rangle^2 \leq \varepsilon \right\} \leq (c_{sb} \varepsilon)^{\alpha} \quad \forall \varepsilon > 0.
\]

42
Since $x_1 = x_2 = \ldots = x_T$, this further simplifies to:

$$\sup_{v \in \mathbb{S}^{n-1}} \mathbb{P} \left\{ \langle v, x_1 \rangle^2 \leq \varepsilon \right\} \leq (c_{sb}\varepsilon)^{\alpha} \forall \varepsilon > 0.$$ 

Since $\langle v, x_1 \rangle \sim \mathcal{N}(0,1)$, this amounts to:

$$\mathbb{P}_{X \sim \mathcal{N}(0,1)} \{ X^2 \leq \varepsilon \} \leq (c_{sb}\varepsilon)^{\alpha} \forall \varepsilon > 0.$$ 

Lemma B.8 yields that $\mathbb{P}_{X \sim \mathcal{N}(0,1)} \{ X^2 \leq \varepsilon \} \leq (\varepsilon)^{1/2}$, so we can take $c_{sb} = e$ and $\alpha = 1/2$. \qed

**Example 4.2** (Gaussian processes). Let $P_x$ be a Gaussian process indexed by time, i.e., for every finite index set $I \subset \mathbb{N}_+$, the collection of random variables $(x_t)_{t \in I}$ is jointly Gaussian. Let $T_{nd} := \inf\{ t \in \mathbb{N}_+ \mid \det(\mathbb{E}[x_t x_t^T]) \neq 0 \}$, and suppose $T_{nd}$ is finite. There exists a positive universal constant $c$ such that the following is true. Fix a $T \in \mathbb{N}_+$ satisfying $T \geq T_{nd}$. Then $P_x$ satisfies the $(T, T, \Gamma_T(P_x), c, \frac{1}{2})$-TrajSB condition.

**Proof.** Since $P_x$ is a Gaussian process, the covariates $(x_1, \ldots, x_T)$ are jointly Gaussian. We can therefore write:

$$\begin{bmatrix} x_1 \\ \vdots \\ x_T \end{bmatrix} = \begin{bmatrix} \mu_1 \\ \vdots \\ \mu_T \end{bmatrix} + \begin{bmatrix} M_1 \\ \vdots \\ M_T \end{bmatrix} w,$$

where $\mu_1, \ldots, \mu_T \in \mathbb{R}^n$ and $M_1, \ldots, M_T \in \mathbb{R}^{n \times nT}$ are fixed, and $w \sim \mathcal{N}(0, I_{nT})$. For any $v \in \mathbb{R}^n$, we therefore have:

$$\frac{1}{T} \sum_{t=1}^{T} \langle v, x_t \rangle^2 = \frac{1}{T} \sum_{t=1}^{T} \langle v, \mu_t + M_tw \rangle^2.$$ 

This is a degree 2 non-negative polynomial in $w$, and therefore by Theorem B.10, for all $\varepsilon > 0$:

$$\mathbb{P} \left\{ \frac{1}{T} \sum_{t=1}^{T} \langle v, x_t \rangle^2 \leq \varepsilon \mathbb{E} \left[ \frac{1}{T} \sum_{t=1}^{T} \langle v, x_t \rangle^2 \right] \right\} \leq (c\varepsilon)^{1/2}.$$ 

The claim now follows by observing:

$$\mathbb{E} \left[ \frac{1}{T} \sum_{t=1}^{T} \langle v, x_t \rangle^2 \right] = \frac{1}{T} \sum_{t=1}^{T} v^T \mathbb{E}[x_t x_t^T] v = v^T \Gamma_T(P_x) v.$$ 

\qed

**Example 4.4** (Alternating halfspaces). Suppose that $n \geq 4$ is even, and let $u_1, \ldots, u_n$ be a fixed orthonormal basis of $\mathbb{R}^n$. Put $U_0 = \text{span}(u_1, \ldots, u_{n/2})$ and $U_1 = \text{span}(u_{n/2+1}, \ldots, u_n)$. Let $i_t \sim \text{Bern}(\frac{1}{2})$, $i_{t+1} = i_t \mod 2$ for $t \in \mathbb{N}_+$, and let $P_x$ denote the process with conditional distribution $x_t \mid i_t$ uniform over the spherical measure on $U_{i_t} \cap \mathbb{S}^{n-1}$. For any $T \geq 2$, the process $P_x$ satisfies the $(T, 2, I_n/(2n), e, \frac{1}{2})$-TrajSB condition.
Proof. For \( i \in \{0,1\} \), let \( \psi_i \) be uniform on the uniform measure over \( U_i \cap \mathbb{S}^{n-1} \), let \( P_{U_i} \) denote the orthogonal projector onto \( U_i \), and let \( v_i = P_{U_i} v \).

Fix any \( v \in \mathbb{R}^n \setminus \{0\} \). We observe that for any \( t \in \mathbb{N}_+ \), \( \langle v, x_{t+1} \rangle^2 + \langle v, x_{t+2} \rangle^2 \mid i_t \) is equal in distribution to \( \langle v, \psi_0 \rangle^2 + \langle v, \psi_1 \rangle^2 \), which itself is equal to \( \langle v_0, \psi_0 \rangle^2 + \langle v_1, \psi_1 \rangle^2 \). Suppose first that \( \|v_0\|_2 \geq \|v_1\|_2 \). Then, since \( \|v\|^2 = \|v_0\|^2 + \|v_1\|^2 \leq 2\|v_0\|^2 \):

\[
\left\{ \langle v_0, \psi_0 \rangle^2 + \langle v_1, \psi_1 \rangle^2 \leq \frac{\varepsilon}{n} \|v\|^2 \right\} \subseteq \left\{ \langle v_0, \psi_0 \rangle^2 + \langle v_1, \psi_1 \rangle^2 \leq \frac{2\varepsilon}{n} \|v_0\|^2 \right\} \\
\subseteq \left\{ \langle v_0, \psi_0 \rangle^2 \leq \frac{2\varepsilon}{n} \|v_0\|_2^2 \right\}.
\]

Writing \( \alpha_0 = (\langle u_1, v \rangle, \ldots, \langle u_{n/2}, v \rangle) \in \mathbb{R}^{n/2} \), by a change of coordinates we have that \( \|\alpha_0\|^2 = \|v_0\|^2 \), and that \( \langle v_0, \psi_0 \rangle \) is equal in distribution to \( \langle \alpha_0, \zeta_0 \rangle \), where \( \zeta_0 \) is uniform on \( \mathbb{S}^{n/2-1} \). Since we assumed \( \|v_0\|_2 \geq \|v_1\|_2 \), we must have that \( \alpha_0 \neq 0 \). Hence by Proposition B.9,

\[
\mathbb{P}\left\{ \langle v_0, \psi_0 \rangle^2 + \langle v_1, \psi_1 \rangle^2 \leq \frac{\varepsilon}{n} \|v\|^2 \right\} \leq \mathbb{P}\left\{ \langle \alpha_0, \zeta_0 \rangle^2 \leq \frac{2\varepsilon}{n} \|\alpha_0\|^2 \right\} \leq (\varepsilon)^{1/2}.
\]

Note that if \( \|v_1\|_2 > \|v_0\|_2 \), an identical argument yields the same bound. Hence, letting \( \mathcal{F}_t = \sigma(x_1, \ldots, x_t) \), we have shown that for all \( t \geq 0 \):

\[
\mathbb{P}\left\{ \frac{1}{2} \sum_{t=1}^n \langle v, x_{t+1} \rangle^2 \leq \varepsilon \cdot v^T \left( \frac{1}{2n} I_n \right) v \mid \mathcal{F}_t \right\} \leq (\varepsilon)^{1/2},
\]

from which the claim follows.

\[ \square \]

Example 4.5 (Normal subspaces). Suppose that \( n \geq 3 \). Let \( u_1, \ldots, u_n \) be a fixed orthonormal basis in \( \mathbb{R}^n \), and let \( U_{i-} := \text{span}(\{u_j\}_{j \neq i}) \) for \( i \in \{1,\ldots,n\} \). Consider the Markov chain \( \{i_t\}_{t \geq 1} \) defined by \( i_1 \sim \text{Unif}(\{1,\ldots,n\}) \), and \( i_{t+1} \mid i_t \sim \text{Unif}(\{1,\ldots,n\} \setminus \{i_t\}) \). Let \( \mathbb{P}_x \) denote the process with conditional distribution \( x_t \mid i_t \) uniform over the spherical measure on \( U_{i_t} \cap \mathbb{S}^{n-1} \). For any \( T \geq 2 \), the process \( \mathbb{P}_x \) satisfies the \( (T,2,I_n/(4n-4),e,\frac{1}{2}) \)-TrajSB condition.

Proof. Fix any \( v \in \mathbb{R}^n \setminus \{0\} \), and for \( i \in \{1,\ldots,n\} \), let \( v_i = P_{U_{i-}}v \), where \( P_{U_{i-}} \) is the orthogonal projector onto \( U_{i-} \). Let \( \{\psi_i\}_{i=1}^n \) be independent random variables, where each \( \psi_i \) is uniform on the uniform measure over \( U_{i-} \cap \mathbb{S}^{n-1} \).

Let indices \( j,k \in \{1,\ldots,n\} \) with \( j \neq k \). We first observe that since \( j \neq k \), we have that \( U_{i-j}^+ = \text{span}(u_j) \subset U_{i-} \). Therefore:

\[
\|v\|^2 = \|v_j\|^2 + \|P_{U_{i-j}} v_j\|^2 \leq \|v_j\|^2 + \|v_k\|^2.
\]

Hence, assuming that \( \|v_j\|_2 \geq \|v_k\|_2 \), we have:

\[
\left\{ \langle v_j, \psi_j \rangle^2 + \langle v_k, \psi_k \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|^2 \right\} \subseteq \left\{ \langle v_j, \psi_j \rangle^2 + \langle v_k, \psi_k \rangle^2 \leq \frac{\varepsilon}{n-1} \|v_j\|^2 \right\} \\
\subseteq \left\{ \langle v_j, \psi_j \rangle^2 \leq \frac{\varepsilon}{n-1} \|v_j\|^2 \right\}.
\]

44
Writing \( \alpha_j = \langle (u_i, v) \rangle_{i \neq j} \in \mathbb{R}^{n-1} \), by a change of coordinates we have that \( \|\alpha_j\|^2_2 = \|v_j\|^2_2 \), and that \( \langle v_j, \psi_j \rangle \) is equal in distribution to \( \langle \alpha_j, \zeta_j \rangle \), where \( \zeta_j \) is uniform on \( \mathbb{S}^{n-2} \). Since we assumed \( \|v_j\|_2 \geq \|v_k\|_2 \), we must have that \( \alpha_j \neq 0 \). Hence by Proposition B.9,

\[
P \left\{ \langle v_j, \psi_j \rangle^2 + \langle v_k, \psi_k \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|_2^2 \mid i_t = i \right\} \leq \frac{1}{2(n-1)} \|v\|_2^2 \mid \|v\|_2^2 \mid i_t = i \}
\]

Note that if \( \|v_k\|_2 > \|v_j\|_2 \), an identical argument yields the same bound.

Now, for any \( i \in \{1, \ldots, n\} \) and \( t \in \mathbb{N}_+ \):

\[
P \left\{ \langle v, x_{t+1} \rangle^2 + \langle v, x_{t+2} \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|_2^2 \mid i_t = i \right\} = \sum_{j \neq i, k \neq j} \P \left\{ \langle v, x_{t+1} \rangle^2 + \langle v, x_{t+2} \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|_2^2 \mid i_t = i, i_{t+1} = j, i_{t+2} = k \right\} \P \left\{ i_{t+1} = j, i_{t+2} = k \mid i_t = i \right\}
\]

\[
= \sum_{j \neq i, k \neq j} \P \left\{ \langle v_j, \psi_j \rangle^2 + \langle v_k, \psi_k \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|_2^2 \right\} \P \left\{ i_{t+1} = j, i_{t+2} = k \mid i_t = i \right\} \leq (\varepsilon)^{1/2} \sum_{j \neq i, k \neq j} \P \left\{ i_{t+1} = j, i_{t+2} = k \mid i_t = i \right\} = (\varepsilon)^{1/2}.
\]

Note we also have that \( \P \left\{ \langle v, x_1 \rangle^2 + \langle v, x_2 \rangle^2 \leq \frac{\varepsilon}{2(n-1)} \|v\|_2^2 \right\} \leq (\varepsilon)^{1/2} \) by a nearly identical argument. Hence, letting \( F_t = \sigma(x_1, \ldots, x_t) \), we have shown that for all \( t \geq 0 \):

\[
P \left\{ \frac{1}{2} \sum_{\ell=1}^{2} \langle v, x_{t+\ell} \rangle^2 \leq \varepsilon \cdot v^T \left( \frac{1}{4(n-1)} I_n \right) v \mid F_t \right\} \leq (\varepsilon)^{1/2},
\]

from which the claim follows.

For the next claim, recall that the mixing time of a Markov chain over state-space \( S \) with transition matrix \( P \) and stationary distribution \( \pi \) is defined as:

\[
\tau_{\text{mix}}(\varepsilon) = \inf \left\{ k \in \mathbb{N} \mid \sup_{\mu \in \mathcal{P}(S)} \| \mu P^k - \pi \|_{tv} \leq \varepsilon \right\}.
\]

Here, \( \mathcal{P}(S) \) denotes the set of distributions over \( S \), and \( \| \|_{tv} \) is the total-variation norm over distributions.

**Proposition B.14.** Let \( n \geq 2 \). Consider the Markov chain \( \{i_t\}_{t \geq 1} \) where \( i_1 \sim \text{Unif}(\{1, \ldots, n\}) \) and \( i_{t+1} \mid i_t \sim \text{Unif}(\{1, \ldots, n\} \setminus \{i_t\}) \). We have that:

\[
\tau_{\text{mix}}(\varepsilon) = \inf \left\{ k \in \mathbb{N} \mid (n-1)^{-k} \leq \frac{2\varepsilon}{1-1/n} \right\}.
\]

**Proof.** Let \( 1 \in \mathbb{R}^n \) denote the all ones vector. The transition matrix for this Markov chain is:

\[
P = \frac{1}{n-1} (11^T - I_n),
\]

45
and its stationary distribution is uniform over \( \{1, \ldots, n\} \). Note that for \( j \geq 1 \), \( (11^T)^j = n^{j-1}11^T \).

Since \( 11^T \) and \( I_n \) commute, by the binomial theorem we have that:

\[
P^k = \frac{1}{(n-1)^k} \sum_{j=0}^{k} \binom{k}{j} (11^T)^{k-j}(-1)^j \]

\[
= \frac{1}{(n-1)^k} \left[ \sum_{j=0}^{k-1} \binom{k}{j} n^{k-j-1}(-1)^j 11^T + (-1)^k I_n \right] \]

\[
= \frac{1}{(n-1)^k} \left[ \frac{1}{n} \left( (n-1)^k - (-1)^k \right) 11^T + (-1)^k I_n \right] \]

\[
= \frac{1}{n} 11^T + \frac{(-1)^k}{(n-1)^k} \left[ I_n - \frac{1}{n} 11^T \right].
\]

Now, let \( \mu \in \mathbb{R}_{\geq 0}^n \) satisfy \( \mu^T 1 = 1 \). We have:

\[
\left\| \mu^T P^k - \frac{1}{n} 11^T \right\|_1 = \frac{1}{(n-1)^k} \left\| \mu - \frac{1}{n} 1 \right\|_1.
\]

It is straightforward to check that \( \sup_{\mu \in \mathbb{R}_{\geq 0}^n, \mu^T 1 = 1} \left\| \mu - \frac{1}{n} 1 \right\|_1 = 1 - \frac{1}{n} \), from which the claim follows, since the TV distance between two distributions \( \mu, \nu \) is \( \| \mu - \nu \|_{tv} = \frac{1}{2} \| \mu - \nu \|_1 \).

**Example 4.6 (Linear dynamical systems).** Let \( (A, B) \) with \( A \in \mathbb{R}^{n \times n} \) and \( B \in \mathbb{R}^{n \times d} \) be \( k_c \)-step-controllable (Definition 4.2). Let \( P_x^{A,B} \) be the linear dynamical system defined in (3.8). Fix any \( T, k \in \mathbb{N}_+ \) satisfying \( T \geq k \geq k_c \). Then, \( P_x^{A,B} \) satisfies the \( (T, k, \Gamma_k(A, B), e, \frac{1}{2}) \)-TrajSB condition.

**Proof.** Let \( \Gamma_k \) be shorthand for \( \Gamma_k(P_x) \) and \( \Sigma_k \) be shorthand for \( \Sigma_k(P_x) \). Let \( w = (w_1, \ldots, w_k) \in \mathbb{R}^{nk} \) denote the vertical concatenation of the process noise variables. Let \( M_t := [A^t \ \Phi_t] \in \mathbb{R}^{n \times n(k+1)} \) denote the matrix such that \( x_t = M_t \begin{bmatrix} x \\ w \end{bmatrix} \). With this notation, for any \( v \in \mathbb{R}^n \):

\[
\frac{1}{k} \sum_{t=1}^{k} \langle v, x_t \rangle^2 = \begin{bmatrix} x \\ w \end{bmatrix}^T \left( \frac{1}{k} \sum_{t=1}^{k} M_t^T v v^T M_t \right) \begin{bmatrix} x \\ w \end{bmatrix}.
\]

By Lemma B.8, for any \( \varepsilon > 0 \),

\[
\mathbb{P} \left\{ \begin{bmatrix} x \\ w \end{bmatrix}^T \left( \frac{1}{k} \sum_{t=1}^{k} M_t^T v v^T M_t \right) \begin{bmatrix} x \\ w \end{bmatrix} \geq \varepsilon \cdot \text{tr} \left( \frac{1}{k} \sum_{t=1}^{k} \Phi_t^T v v^T \Phi_t \right) \right\} \leq (\varepsilon \varepsilon)^{1/2}.
\]

On the other hand:

\[
\text{tr} \left( \frac{1}{k} \sum_{t=1}^{k} \Phi_t^T v v^T \Phi_t \right) = v^T \left( \frac{1}{k} \sum_{t=1}^{k} \Phi_t \Phi_t^T \right) v = v^T \left( \frac{1}{k} \sum_{t=1}^{k} \Sigma_t \right) v = v^T \Gamma_k v.
\]

Because we assumed that \( k \geq k_c \), then \( \Gamma_k \) is invertible. Thus, we can take \( c_{sb} = e \) and \( \alpha = 1/2 \).
Proposition B.15. Consider the scalar stochastic process \( \{x_t\}_{t \geq 1} \) defined by:

\[
x_t = \sum_{i=0}^{t-1} \sum_{j=0}^{t-1} c_{i,j} w_{t-i-1} w_{t-j-1},
\]

where \( \{c_{i,j}\}_{i,j \geq 0} \) are the coefficients which describe the dynamics, and \( \{w_t\}_{t \geq 0} \) are iid \( N(0,1) \) random variables. Let \( \{\mathcal{F}_t\}_{t \geq 1} \) denote the filtration defined as \( \mathcal{F}_t := \sigma(w_0, ..., w_{t-1}) \), so that \( x_t \) is \( \mathcal{F}_t \)-measurable. Suppose that \( \{c_{i,j}\}_{i,j \geq 0} \) is symmetric and traceless. For every \( t \geq 1 \) and \( k \geq 0 \), almost surely we have:

\[
\mathbb{E}[x_{t+k}^2 | \mathcal{F}_k] \geq \mathbb{E}[x_t^2] + (\mathbb{E}[x_{t+k} | \mathcal{F}_k])^2.
\]

Proof. For \( t \geq 1 \), define the symmetric matrices

\[
M_t \in \mathbb{R}^{t \times t} \text{ with } (M_t)_{ii} = 0 \text{ and } (M_t)_{ij} = c(i-1)(j-1).
\]

With this notation and with \( \tilde{w}_t \sim N(0, I_t) \), we can write \( x_t \) as:

\[
x_t = \tilde{w}_t^T M_t \tilde{w}_t.
\]

Therefore, by Proposition B.6 and the assumption that \( \text{tr}(M_t) = 0 \):

\[
\mathbb{E}[x_t^2] = \mathbb{E}(\tilde{w}_t^T M_t \tilde{w}_t) = 2\|M_t\|_F^2 + \text{tr}(M_t)^2 = 2\|M_t\|_F^2.
\]

Now, partition \( M_{t+k} \) as:

\[
M_{t+k} = \begin{bmatrix} M_t & D_{t,k} \\ D_{t,k}^T & E_{t,k} \end{bmatrix}.
\]

Let \( \tilde{v}_k = (w_{k-1}, ..., w_0) \). Given \( \mathcal{F}_k \), we can write \( x_{t+k} \) as:

\[
x_{t+k} = \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix}^T \begin{bmatrix} M_t & D_{t,k} \\ D_{t,k}^T & E_{t,k} \end{bmatrix} \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix}.
\]

Expanding the square:

\[
\left( \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix}^T \begin{bmatrix} M_t & D_{t,k} \\ D_{t,k}^T & E_{t,k} \end{bmatrix} \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix} \right)^2 = (\tilde{w}_t^T M_t \tilde{w}_t + 2\tilde{w}_t^T D_{t,k} \tilde{v}_k + \tilde{v}_k^T E_{t,k} \tilde{v}_k)^2
\]

\[
= (\tilde{w}_t^T M_t \tilde{w}_t)^2 + 4\tilde{w}_t^T M_t \tilde{w}_t \tilde{v}_k^T D_{t,k} \tilde{v}_k + 2\tilde{w}_t^T M_t \tilde{w}_t \tilde{v}_k^T E_{t,k} \tilde{v}_k + 4\tilde{v}_k^T E_{t,k} \tilde{v}_k^T E_{t,k} \tilde{v}_k + (\tilde{v}_k^T E_{t,k} \tilde{v}_k)^2.
\]

Using Proposition B.6 again:

\[
\mathbb{E}[x_{t+k}^2 | \mathcal{F}_k] = \mathbb{E}_{\tilde{w}_t} \left( \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix}^T \begin{bmatrix} M_t & D_{t,k} \\ D_{t,k}^T & E_{t,k} \end{bmatrix} \begin{bmatrix} \tilde{w}_t \\ \tilde{v}_k \end{bmatrix} \right)^2
\]

\[
= \mathbb{E}_{\tilde{w}_t} (\tilde{w}_t^T M_t \tilde{w}_t)^2 + 2\text{tr}(M_t)\tilde{v}_k^T E_{t,k} \tilde{v}_k + 4\|D_{t,k} \tilde{v}_k\|_2^2 + (\tilde{v}_k^T E_{t,k} \tilde{v}_k)^2
\]

\[
= 2\|M_t\|_F^2 + 2\text{tr}(M_t)^2 + 4\|D_{t,k} \tilde{v}_k\|_2^2 + (\tilde{v}_k^T E_{t,k} \tilde{v}_k)^2
\]

\[
\geq 2\|M_t\|_F^2 + (\tilde{v}_k^T E_{t,k} \tilde{v}_k)^2.
\]

To complete the proof, we recall that \( \mathbb{E}[x_t^2] = 2\|M_t\|_F^2 \) and \( \mathbb{E}[x_{t+k} | \mathcal{F}_k] = \tilde{v}_k^T E_{t,k} \tilde{v}_k \).
Example 4.8 (Degree-2 Volterra series). Consider the following process \( P_x \). Let \( \{c_{i,j}^{(t)}\}_{i,j \geq 0} \) for \( \ell \in \{1, ..., n\} \) be symmetric, traceless, non-degenerate arrays (Definition 4.3). Let \( \{w_i^{(t)}\}_{t \geq 0} \) be iid \( N(0,1) \) random variables for \( \ell \in \{1, ..., n\} \). For \( t \geq 1 \), the \( \ell \)-th coordinate of \( x_t \), denoted \( (x_t)_\ell \), is:

\[
(x_t)_\ell = \sum_{i=0}^{t-1} \sum_{j=i}^{t-1} c_{i,j}^{(t)} w_{t-i-1}^{(t)} w_{t-j-1}^{(t)}.
\] (4.12)

Let \( k_{nd} \in \mathbb{N}_+ \) denote the smallest non-degeneracy index for all \( n \) arrays. There is a universal positive constant \( c \) such that for any \( T \) and \( k \) satisfying \( T \geq k \geq k_{nd} \), \( P_x \) satisfies the \((T,k,\Gamma_k(P_x),c,\frac{1}{2})\)-TrajSB condition.

Proof. Fix a \( v \in \mathbb{R}^n \). The relation (4.12) shows that \( \langle v, x_t \rangle^2 \) is a degree four polynomial in \( \{w_i^{(t)}\}_{i=0, \ell = 1}^{t-1,n} \). Let \( \mathcal{F}_t = \sigma(\{w_i^{(t)}\}_{i=0, \ell = 1}^{t-1,n}) \), so that \( x_t \) is \( \mathcal{F}_t \)-measurable. By Theorem B.10, there exists a universal positive constant \( c \) so that for any \( s \geq 0 \),

\[
\mathbb{P} \left\{ \frac{1}{k} \sum_{t=1}^{k} \langle v, x_{t+s} \rangle^2 \leq c \mathbb{E} \left[ \frac{1}{k} \sum_{t=1}^{k} \langle v, x_{t+s} \rangle^2 \mid \mathcal{F}_s \right] \mid \mathcal{F}_s \right\} \leq (ce)^{1/4} \text{ a.s.}
\]

To conclude the proof, we need to lower bound \( \mathbb{E} \left[ \frac{1}{k} \sum_{t=1}^{k} \langle v, x_{t+s} \rangle^2 \mid \mathcal{F}_s \right] \). For any \( t \geq 1 \),

\[
\mathbb{E} \left[ \langle v, x_{t+s} \rangle^2 \mid \mathcal{F}_s \right] = \mathbb{E} \left[ \left( \sum_{\ell=1}^{n} v_\ell \cdot (x_{t+s})_\ell \right)^2 \mid \mathcal{F}_s \right]
\]

\[
= \sum_{\ell=1}^{n} v_\ell^2 \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell^2 \mid \mathcal{F}_s] + \sum_{\ell_1 \neq \ell_2} v_{\ell_1} v_{\ell_2} \cdot \mathbb{E}[\langle x_{t+s} \rangle_{\ell_1} \mid \mathcal{F}_s] \cdot \mathbb{E}[\langle x_{t+s} \rangle_{\ell_2} \mid \mathcal{F}_s]
\]

\[
\geq \sum_{\ell=1}^{n} v_\ell^2 \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell^2] + \sum_{\ell=1}^{n} v_\ell \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell \mid \mathcal{F}_s]^2
\]

\[
= \sum_{\ell=1}^{n} v_\ell^2 \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell^2] + \left( \sum_{\ell=1}^{n} v_\ell \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell \mid \mathcal{F}_s] \right)^2
\]

\[
\geq \sum_{\ell=1}^{n} v_\ell^2 \cdot \mathbb{E}[\langle x_{t+s} \rangle_\ell^2] \geq v^T \Sigma_t(P_x)v.
\]

Above, (a) follows since each coordinate of \( x_t \) is independent by definition, (b) follows from Proposition B.15, and (c) follows since \( \mathbb{E}[x_1] = 0 \) and each coordinate is independent, so \( \mathbb{E}[x_{t+s}]_{\ell_1}(x_{t+s})_{\ell_2} = \mathbb{E}[(x_t)_{\ell_1}](x_t)_{\ell_2} = 0 \) for \( \ell_1 \neq \ell_2 \). Hence, we have shown:

\[
\mathbb{E} \left[ \frac{1}{k} \sum_{t=1}^{k} \langle v, x_{t+s} \rangle^2 \mid \mathcal{F}_s \right] \geq v^T \left( \frac{1}{k} \sum_{t=1}^{k} \Sigma_t(P_x) \right) v = v^T \Gamma_k(P_x)v.
\]

Note that because we assume that \( k \geq k_{nd} \), the covariances \( \Sigma_t(P_x) \) are all invertible (and hence so is \( \Gamma_k(P_x) \)). The claim now follows. \( \square \)
Let $T \ell \in \mathbb{N}$ and $\ell \in \{1, \ldots, n\}$ denote arbitrary rank-$d$ arrays. Let $\{w_t^{(\ell)}\}_{t \geq 0}$ be iid $N(0,1)$ random variables for $\ell \in \{1, \ldots, n\}$. Consider the process $P_x$ where for $t \geq 1$, the $\ell$-th coordinate of $x_t$, denoted $(x_t)_{\ell}$, is:

$$(x_t)_{\ell} = \sum_{d=1}^{D} \sum_{t=0}^{T-1} c_{t_d}^{(d,\ell)} \prod_{d'=1}^{d} w_{t-d'}^{(\ell)}$$

(4.11)

Let $T_{nd} := \inf\{t \in \mathbb{N} \mid \det(\Gamma_t(P_x)) \neq 0\}$, and suppose $T_{nd}$ is finite. There is a constant $c_D > 0$, depending only on $D$, such that for any $T \geq T_{nd}$, $P_x$ satisfies the $(T,T,\Gamma_T(P_x),c_D,1/(2D))$-TrajSB condition.

**Proof.** Fix a $v \in \mathbb{R}^n$. The definition (4.11) expresses $(v,x_t)$ as a degree at most $D$ polynomial in the noise variables $\{w_t^{(\ell)}\}$. By Theorem B.10, there exists a positive constant $c_D$, only depending on $D$, such that:

$$\mathbb{P}\left\{ \frac{1}{T} \sum_{t=1}^{T} (v,x_t)^2 \leq \varepsilon \mathbb{E}\left[ \frac{1}{T} \sum_{t=1}^{T} (v,x_t)^2 \right] \right\} \leq (c_D \varepsilon)^{1/(2D)}.$$  

Next, we observe that:

$$\mathbb{E}\left[ \frac{1}{T} \sum_{t=1}^{T} (v,x_t)^2 \right] = v^T \left( \frac{1}{T} \sum_{t=1}^{T} \Sigma_t(P_x) \right) v = v^T \Gamma_T(P_x)v.$$  

Since $T \geq T_{nd}$, the matrix $\Gamma_T(P_x)$ is invertible. The claim now follows. \hfill \Box

### B.3 Proof of Proposition 4.4

**Proposition 4.4** (Average small-ball implies trajectory small-ball). Fix $T \in \mathbb{N}$, $k \in \{1, \ldots, T\}$, $\{\Psi_j\}_{j=1}^{T/k} \subseteq \text{Sym}^n_{>0}$, $c_{sb} > 1$, and $\alpha \in (0,1]$. Let $P_x$ be a covariate distribution, with $\{x_t\}_{t \geq 1}$ adapted to a filtration $\{\mathcal{F}_t\}_{t \geq 1}$. Suppose for all $v \in \mathbb{R}^n \setminus \{0\}$, $j \in \{1, \ldots, [T/k]\}$, and $\varepsilon > 0$:

$$\frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \mathbb{P}_{x_t \sim P_x} \left\{ (v,x_t)^2 \leq \varepsilon \cdot v^T \Psi_j v \mid \mathcal{F}_{(j-1)k} \right\} \leq (c_{sb} \varepsilon)^{\alpha} \text{ a.s.},$$

(4.13)

where $\mathcal{F}_0$ is the minimal $\sigma$-algebra. Then, for all $v \in \mathbb{R}^n \setminus \{0\}$, $j \in \{1, \ldots, [T/k]\}$, and $\varepsilon > 0$:

$$\mathbb{P}_{\{x_t\} \sim P_x} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} (v,x_t)^2 \leq \varepsilon \cdot v^T \Psi_j v \mid \mathcal{F}_{(j-1)k} \right\} \leq (c'_{sb} \varepsilon)^{\alpha} \text{ a.s.},$$

(4.14)

where $c'_{sb} := c_{sb}/(1 - 1/c_{sb})^{1/\alpha}$.

**Proof.** The following proof builds on the argument given in Simchowitz et al. (2018, Section E.1). We note that a similar style of proof is used in Bartlett et al. (2020, Lemma 15).
We assume that \( \epsilon \in (0, 1/c_{sb}) \), otherwise (4.14) holds vacuously. Define the shorthand notation 
\( \mathbb{P}_t \{ \cdot | F_t \} := \mathbb{P} \{ \cdot | F_t \} \). Now fix a \( v \in \mathbb{R}^n \setminus \{ 0 \} \), \( j \in \{ 1, \ldots, [T/k] \} \), and \( \epsilon > 0 \). Markov’s inequality yields that:
\[
\mathbb{P}_{(j-1)k} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, x_t \rangle^2 \leq \epsilon \cdot v^T \Psi_j v \right\} \leq \mathbb{P}_{(j-1)k} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} 1 \{ \langle v, x_t \rangle^2 > v^T \Psi_j v \} \right\}.
\]
and therefore:
\[
\mathbb{P}_{(j-1)k} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, x_t \rangle^2 \leq \epsilon \cdot v^T \Psi_j v \right\} \leq \mathbb{P}_{(j-1)k} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} 1 \{ \langle v, x_t \rangle^2 > v^T \Psi_j v \} \right\}.
\]
Define \( Z_j := \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} 1 \{ \langle v, x_t \rangle^2 > v^T \Psi_j v \} \), and observe that \( Z_j \in [0, 1] \). By (4.13), we have:
\[
\mathbb{E}_{(j-1)k}[Z_j] \geq 1 - (c_{sb}\epsilon)^\alpha.
\]
On the other hand:
\[
\mathbb{E}_{(j-1)k}[Z_j] = \mathbb{E}_{(j-1)k}[Z_j 1 \{ Z_j > \epsilon \}] + \mathbb{E}_{(j-1)k}[Z_j 1 \{ Z_j \leq \epsilon \}]
= 1 - (1 - \epsilon)\mathbb{P}_{(j-1)k}\{ Z_j \leq \epsilon \}
\leq 1 - (1 - 1/c_{sb})\mathbb{P}_{(j-1)k}\{ Z_j \leq \epsilon \}
\]
Combining both these inequalities and noting that \( 1 - 1/c_{sb} > 0 \) (since \( c_{sb} > 1 \) by assumption):
\[
\mathbb{P}_{(j-1)k}\{ Z_j \leq \epsilon \} \leq (c_{sb}\epsilon)^\alpha (1 - 1/c_{sb})^{1/\alpha} = (c_{sb}')^\alpha.
\]
This yields the desired inequality (4.14). \( \Box \)

### B.4 General ordinary least-squares estimator upper bound

In this section, we supply the proof of Lemma 4.1. We first start with a result which bounds the
minimum eigenvalue of the empirical covariance matrix.

**Lemma B.16.** Suppose that \( P_x \) satisfies the \((T, k, \{ \Psi_j \}_{j=1}^{[T/k]}, c_{sb}, \alpha)\)-trajectory-small-ball condition (Definition 4.1). Put \( S := [T/k] \), and \( \Gamma_T := \Gamma_T(P_x) \). Fix any \( \Gamma \in \mathbb{R}^{n \times n} \) satisfying \( \frac{1}{2} \sum_{j=1}^{S} \Psi_j \ll \Gamma \ll \Gamma_T \). Define \( \tilde{X}_{m,T} := X_{m,T} \Gamma^{-1/2} \), and:
\[
\mu(\{ \Psi_j \}_{j=1}^{S}, \Gamma) := \left[ \prod_{j=1}^{S} \Lambda(\Psi_j, \Gamma) \right]^{1/S}.
\]
(B.1)

**Suppose that:**
\[
n \geq 2, \quad \frac{mT}{k} \geq \frac{n}{c_{sb}}, \quad \frac{mT}{k} \geq 8n \left[ 1 + \log \left( \frac{5 \max\{1, c_{sb}\} mT}{kn\Lambda(\Gamma, \Gamma_T) \mu(\{ \Psi_j \}_{j=1}^{S}, \Gamma)} \right) \right].
\]
(B.2)
For any \( t \geq 0 \), with probability at least \( 1 - 2e^{-t} \), the following statements simultaneously hold:

\[
\text{tr}(\hat{X}_{m,T}^{\top} \hat{X}_{m,T}) \leq \frac{mTn e^t}{\lambda(\Gamma, \Gamma_T)}, \quad \lambda_{\min}(\hat{X}_{m,T}^{\top} \hat{X}_{m,T}) \geq \frac{mT \alpha \mu((\Psi_j)_{j=1}^S)^S 16 k \nu}{8e c_{sb}} \exp \left(-\frac{16 k \nu t}{m T \alpha} \right).
\]

**Proof.** For notational brevity, let:

\[
\lambda := \lambda(\Gamma, \Gamma_T), \quad \mu := \mu((\Psi_j)_{j=1}^S, \Gamma).
\]

Since \( \Gamma \leq \Gamma_T \) by assumption, we have \( \lambda \in (0, 1] \). Similarly, since \( \frac{1}{S} \sum_{j=1}^S \Psi_j \leq \Gamma \), we also have \( \mu \in (0, 1] \) by Proposition B.4.

The trajectory small-ball condition (4.1) implies, that for any \( v \in S^{n-1}, j \in \{1, ..., S\} \), and \( \varepsilon > 0 \),

\[
\mathbb{P} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, \Gamma^{-1/2} x_t \rangle^2 \leq \varepsilon \mathbb{L}(\Psi_j, \Gamma) \bigg| \mathcal{F}_{(j-1)k} \right\} \leq (c_{ab} \varepsilon)^{\alpha}.
\]

Using a change of variables \( \varepsilon \leftarrow \varepsilon / \mathbb{L}(\Psi_j, \Gamma) \),

\[
\mathbb{P} \left\{ \frac{1}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, \Gamma^{-1/2} x_t \rangle^2 \leq \varepsilon \bigg| \mathcal{F}_{(j-1)k} \right\} \leq (c_{ab} / \mathbb{L}(\Psi_j, \Gamma) : \varepsilon)^{\alpha}.
\]

By Proposition B.5, for any \( \eta > 0 \),

\[
\mathbb{E} \left[ \exp \left( -\frac{\eta}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, \Gamma^{-1/2} x_t \rangle^2 + \alpha \log \left( \frac{\eta \mathbb{L}(\Psi_j, \Gamma)}{c_{sb}} \right) \right) \bigg| \mathcal{F}_{(j-1)k} \right] \leq 1 \text{ a.s.} \quad (B.3)
\]

For \( i \in \{1, ..., m\} \) and \( j \in \{1, ..., S\} \), define the random variables \( Z_j^{(i)}(v; \eta) \), \( Z^{(i)}(v; \eta) \), and \( Z(v; \eta) \):

\[
Z_j^{(i)}(v; \eta) := -\frac{\eta}{k} \sum_{t=(j-1)k+1}^{jk} \langle v, \Gamma^{-1/2} x_t^{(i)} \rangle^2 + \alpha \log \left( \frac{\eta \mathbb{L}(\Psi_j, \Gamma)}{c_{sb}} \right),
\]

\[
Z^{(i)}(v; \eta) := \sum_{j=1}^S Z_j^{(i)}(v; \eta),
\]

\[
Z(v; \eta) := \sum_{i=1}^m Z^{(i)}(v; \eta).
\]

We first claim that \( \mathbb{E}[\exp(Z(v; \eta))] \leq 1 \) for every \( v \in S^{n-1} \) and \( \eta > 0 \). Since \( Z^{(i)}(v; \eta) \) is independent of \( Z^{(i')}(v; \eta) \) whenever \( i \neq i' \), we have that:

\[
\mathbb{E}[\exp(Z(v; \eta))] = \mathbb{E} \left[ \exp \left( \sum_{i=1}^m Z^{(i)}(v; \eta) \right) \right] = \prod_{i=1}^m \mathbb{E}[\exp(Z^{(i)}(v; \eta))].
\]
Furthermore, by repeated applications of the tower property and (B.3), for every $i \in \{1, \ldots, m\}$,

$$
\mathbb{E}[\exp(Z^{(i)}(v; \eta))] = \mathbb{E}\left[ \exp \left( \sum_{j=1}^{S} Z^{(j)}_{i}(v; \eta) \right) \right] \\
= \mathbb{E}\left[ \exp \left( \sum_{j=1}^{S-1} Z^{(j)}_{i}(v; \eta) \right) \mathbb{E}[\exp(Z^{(i)}_{S}(v; \eta)) \mid F_{(S-1)k}] \right] \\
\leq \mathbb{E}\left[ \exp \left( \sum_{j=1}^{S-1} Z^{(j)}_{i}(v; \eta) \right) \right] \quad \vdots \\
\leq 1.
$$

Hence $\mathbb{E}[\exp(Z(v; \eta))] \leq 1$ for every $v \in \mathbb{S}^{n-1}$ and $\eta > 0$.

Let us now import some more notation from Mourtada (2019). First, let $\pi$ denote the spherical measure on $\mathbb{S}^{n-1}$, and let $\rho_{v, \gamma}$ denote the uniform measure over the spherical cap

$$
C(v, \gamma) := \{w \in \mathbb{S}^{n-1} : \|v - w\|_2 \leq \gamma\}.
$$

Next, let $F_{v, \gamma}(\Sigma) := \int_{C(v, \gamma)} \langle w, \Sigma w \rangle d\rho_{v, \gamma}$ for any symmetric matrix $\Sigma$.

Fix any positive $t, \eta$. For two measures $\mu$ and $\nu$ with $\mu$ absolutely continuous w.r.t. $\nu$, let $\text{KL}(\mu, \nu) := \mathbb{E}_\mu \log \left( \frac{d\mu}{d\nu} \right)$ denote the KL-divergence between $\mu$ and $\nu$. By the PAC-Bayes deviation bound (Mourtada, 2019, Lemma 8), there exists an event $\mathcal{E}_{t,1}$ with probability at least $1 - e^{-t}$, such that on $\mathcal{E}_{t,1}$, we have for every $v \in \mathbb{S}^{n-1}$ and $\gamma > 0$,

$$
- \frac{\eta}{k} F_{v, \gamma} \left( \Gamma^{-1/2} \sum_{i=1}^{m} \sum_{t=1}^{kS} \langle x^{(i)}_{t}, x^{(i)}_{t} \rangle \Gamma^{-1/2} \right) + mS\alpha \log \left( \frac{\eta_{\mu}}{c_{sb}} \right) \leq \text{KL}(\rho_{v, \gamma}, \pi) + t. 
$$

(B.4)

Next, by the arguments in Mourtada (2019, Section 5.3), we can write $F_{v, \gamma}$ in terms of a scalar function $\phi$ such that:

$$
F_{v, \gamma}(\Sigma) = (1 - \phi(\gamma)) \langle v, \Sigma v \rangle + \phi(\gamma) \frac{1}{n} \text{tr}(\Sigma), \quad \phi(\gamma) \in \left[ 0, \frac{n}{n - 1} \gamma^2 \right].
$$

(B.5)

Furthermore, by the arguments in Mourtada (2019, Section 5.4), for every $v \in \mathbb{S}^{n-1}$ and $\gamma > 0$, the KL-divergence term can be upper bounded by:

$$
\text{KL}(\rho_{v, \gamma}, \pi) \leq n \log \left( 1 + \frac{2}{\gamma} \right).
$$

(B.6)

Therefore on $\mathcal{E}_{t,1}$, plugging (B.5) and (B.6) into (B.4),

$$
\lambda_{\min} \left( \tilde{X}_{m,T}^{T} \tilde{X}_{m,T} \right) \\
\geq \frac{k}{\eta(1 - \phi(\gamma))} \left[ mS\alpha \log \left( \frac{\eta_{\mu}}{c_{sb}} \right) - n \log \left( 1 + \frac{2}{\gamma} \right) - t \right] - \frac{\phi(\gamma)}{1 - \phi(\gamma)} \frac{1}{n} \text{tr} \left( \tilde{X}_{m,T}^{T} \tilde{X}_{m,T} \right).
$$
Restricting $\gamma \in [0, 1/2]$, we have from (B.5) that $0 \leq \phi(\gamma) \leq \frac{n}{n-1}\gamma^2 \leq 2\gamma^2 \leq 1/2$. Hence, $1 - \phi(\gamma) \in [1/2, 1]$. Furthermore, $1 + 2/\gamma \leq 5/(4\gamma^2)$. Therefore, setting $\lambda = x$, the function attains a minimum value of $\lambda = \frac{A}{C}$.

Define the non-negative random variables $\psi_i := \sum_{t=1}^{T} ||\Gamma^{-1/2}x_t^{(i)}||^2$, for $i = 1, \ldots, m$. It is straightforward to verify that $\text{tr}(\tilde{X}_{m,T}^T\tilde{X}_{m,T}) = \sum_{i=1}^{m} \psi_i$. By Markov's inequality, for any $\beta > 0$:

$$
\mathbb{P} \left( \text{tr}(\tilde{X}_{m,T}^T\tilde{X}_{m,T}) > \beta \right) = \mathbb{P} \left( \sum_{i=1}^{m} \psi_i > \beta \right) \leq \mathbb{E} \left[ \sum_{i=1}^{m} \psi_i \right] \leq \frac{m \mathbb{E}[\psi_1]}{\beta} = \frac{m \text{tr}(\Gamma^{-1}\Sigma_T)}{\beta} = \frac{mT \text{tr}(\Gamma^{-1}\Gamma_T)}{\beta} \leq \frac{mTn\lambda_{\max}(\Gamma_T^{-1}\Gamma_T)}{\beta} = \frac{mTn}{\lambda \beta}.
$$

Therefore, setting $\beta = \frac{\epsilon' m T n}{\Delta}$, there exists an event $\mathcal{E}_{t,2}$ such that $\mathbb{P}(\mathcal{E}_{t,2}) \leq e^{-t}$, and furthermore on $\mathcal{E}_{t,2}$,

$$
\text{tr}(\tilde{X}_{m,T}^T\tilde{X}_{m,T}) \leq \frac{\epsilon' m T n}{\Delta}.
$$

Therefore on $\mathcal{E}_{t,1} \cap \mathcal{E}_{t,2}$, which we assume holds for the remainder of the proof, we have:

$$
\lambda_{\min} \left( \tilde{X}_{m,T}^T\tilde{X}_{m,T} \right) \geq \frac{k}{\eta} \left[ m \log \left( \frac{n\mu}{e_{sb}} \right) - n \log \left( \frac{5}{4\gamma^2} \right) - t \right] - \frac{4mT \epsilon t}{\Delta} \gamma^2.
$$

Next, we further restrict $\frac{n\mu}{e_{sb}} \geq e$ so that $\log\left(\frac{n\mu}{e_{sb}}\right) \leq 1$. Now consider, for positive constants $A, B, C$, the function $x \mapsto A \log(B/x) + C x$ on the domain $(0, \infty)$. The derivative vanishes at $x = A/C$, and the function attains a minimum value of $A(1 + \log(BC/A))$ with this choice of $x$. Let us set:

$$
A \leftarrow \frac{kn}{\eta}, \quad B \leftarrow \frac{5}{4}, \quad C \leftarrow \frac{4mT \epsilon t}{\Delta}, \quad x \leftarrow \gamma^2.
$$

Then by choosing $\gamma^2 = \frac{kn\lambda}{4mT \epsilon t}$, we have that:

$$
\frac{kn}{\eta} \log \left( \frac{5}{4\gamma^2} \right) + \frac{4mT \epsilon t}{\Delta} \gamma^2 = \frac{kn}{\eta} \left[ 1 + \log \left( \frac{5mT \epsilon t \eta}{kn\lambda} \right) \right].
$$

Note that this choice of $\gamma$ satisfies $\gamma \in [0, 1/2]$, since:

$$
\frac{kn\lambda}{4mT \epsilon t} \leq \frac{1}{4} \iff \frac{kn}{\eta m T} \leq 1 \quad \text{since } t \geq 0 \text{ and } \Delta \leq 1
$$

$$
\iff \frac{kn\mu}{e_{sb} m T} \leq 1 \quad \text{since } \eta \geq e_{sb}/\mu
$$

$$
\iff \frac{n\mu}{e_{sb}} \leq \frac{mT}{k} \quad \text{since } \mu \leq 1,
$$

53
and the last condition holds by (B.2). With this choice of $\gamma$, we have:

$$
\lambda_{\min} \left( \tilde{X}_{m,T}^T \tilde{X}_{m,T} \right) \\
\geq \frac{k}{\eta} \left[ mS \alpha \log \left( \frac{\eta \mu}{c_{sb}} \right) - t - n \left( 1 + \log \left( \frac{5mTe^t \eta}{kn \lambda} \right) \right) \right] \\
= \frac{k}{\eta} \left[ (mS - n) \log \left( \frac{\eta \mu}{c_{sb}} \right) - t - n \left( 1 + \log \left( \frac{5c_{sb}mTe^t}{kn \lambda \mu} \right) \right) \right] \\
\geq \frac{k}{2} \frac{mS \alpha}{\eta} \log \left( \frac{\eta \mu}{c_{sb}} \right) - t - n \left( 1 + \log \left( \frac{5c_{sb}mTe^t}{kn \lambda \mu} \right) \right) \quad \text{since } mS \geq 2n/\alpha \\
= \frac{k}{2} \frac{mS \alpha}{\eta} \log \left( \frac{\eta \mu}{c_{sb}} \right) - (1 + n)t - n \left( 1 + \log \left( \frac{5c_{sb}mT}{kn \lambda \mu} \right) \right) \\
\geq \frac{k}{2} \frac{mS \alpha}{\eta} \log \left( \frac{\eta \mu}{c_{sb}} \right) - 2nt - n \left( 1 + \log \left( \frac{5c_{sb}mT}{kn \lambda \mu} \right) \right) \quad \text{since } \frac{mS \alpha}{4n} \geq 1 + \log \left( \frac{5c_{sb}mT}{kn \lambda \mu} \right) \\
= \frac{kmS \alpha}{4c_{sb} \mu} \left[ \log \left( \frac{\eta \mu}{c_{sb}} \right) - \frac{8nt}{mS \alpha} \right].
$$

(B.7)

It remains to optimize over $\eta \in [ec_{sb}/\mu, \infty)$. For any $G \in \mathbb{R}$, the function $\eta' \mapsto \log \eta' - G$ on $(0, \infty)$ attains a maximum at $\eta' = \exp(1 + G)$. Hence, setting $\eta = \frac{c_{sb}}{\mu} \exp(1 + 8nt/(mS \alpha))$, which satisfies $\eta \geq ec_{sb}/\mu$, we have:

$$
\lambda_{\min} \left( \tilde{X}_{m,T}^T \tilde{X}_{m,T} \right) \geq \frac{kmS \alpha \mu}{4ec_{sb}} \exp \left( - \frac{8nt}{mS \alpha} \right) \\
= \frac{mT \alpha \mu}{8ec_{sb}} \exp \left( - \frac{16knT}{mT \alpha} \right) \quad \text{since } S \geq T/(2k) \text{ by Proposition B.1}.
$$

\[ \square \]

**Corollary B.17.** Assume the hypothesis of Lemma B.16 hold. Then, $\tilde{X}_{m,T}^T \tilde{X}_{m,T}$ is invertible almost surely.

**Proof.** For any $t \geq 0$, define the event $\mathcal{E}_t$ as:

$$
\mathcal{E}_t := \left\{ \lambda_{\min} \left( \tilde{X}_{m,T}^T \tilde{X}_{m,T} \right) > \frac{mT \alpha \mu}{8ec_{sb}} \exp \left( - \frac{16knT}{mT \alpha} \right) \right\}.
$$

The event $\{\lambda_{\min}(\tilde{X}_{m,T}^T \tilde{X}_{m,T}) = 0\}$ is the intersection $\bigcap_{t=1}^\infty \mathcal{E}_t$. By Lemma B.16, we have that $\mathbb{P}(\mathcal{E}_t) \leq 2e^{-t}$. Since the events $\mathcal{E}_{t'} \subseteq \mathcal{E}_t$ whenever $t' \geq t$, by continuity of measure from above,

$$
\mathbb{P}(\lambda_{\min}(\tilde{X}_{m,T}^T \tilde{X}_{m,T}) = 0) = \mathbb{P} \left( \bigcap_{t=1}^\infty \mathcal{E}_t \right) = \lim_{t \to \infty} \mathbb{P}(\mathcal{E}_t) \leq \lim_{t \to \infty} 2e^{-t} = 0.
$$

\[ \square \]
We are now ready to restate and prove Lemma 4.1.

**Lemma 4.1** (General OLS upper bound). There are universal positive constants $c_0$ and $c_1$ such that the following holds. Suppose that $P_x$ satisfies the $(T, k, \{\Psi_j\}_{j=1}^{[T/k]}, c_{sb}, \alpha)$-TrajSB condition (Definition 4.1). Put $S := [T/k]$ and $\Gamma_t := \Gamma_t(P_x)$ for $t \in \mathbb{N}_+$. Fix any $\Gamma \in \text{Sym}_{n>0}$ satisfying $\frac{1}{S} \sum_{j=1}^{S} \Psi_j \preceq \Gamma \preceq \Gamma_T$, and let $\mu(\{\Psi_j\}_{j=1}^{S}, \Gamma)$ denote the geometric mean of the minimum eigenvalues $\{\lambda(\Psi_j, \Gamma)\}_{j=1}^{S}$, i.e.,

$$\mu(\{\Psi_j\}_{j=1}^{S}, \Gamma) := \left( \prod_{j=1}^{S} \lambda(\Psi_j, \Gamma) \right)^{1/S}. \tag{4.3}$$

Suppose that:

$$n \geq 2, \quad \frac{mT}{kn} \geq c_0 \max\left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \log\left( \frac{\max\{e, c_{sb}\}}{\alpha \lambda(\Gamma, \Gamma_T) \mu(\{\Psi_j\}_{j=1}^{S}, \Gamma)} \right) \right\}. \tag{4.4}$$

Then, for any $\Gamma' \in \text{Sym}_{n>0}$:

$$\mathbb{E}[\|\hat{W}_{m,T} - W_{\star}\|^2_{\Gamma'} \leq c_1 c_{sb} \sigma_\xi^2 \cdot \frac{mT \alpha \lambda(\Gamma, \Gamma')}{mT \alpha \lambda(\Gamma, \Gamma')} \cdot \log\left( \frac{\max\{e, c_{sb}\}}{\alpha \lambda(\Gamma, \Gamma_T) \mu(\{\Psi_j\}_{j=1}^{S}, \Gamma)} \right). \tag{4.5}$$

**Proof.** For notational brevity, let:

$$\Delta := \Delta(\Gamma, \Gamma_T), \quad \mu := \mu(\{\Psi_j\}_{j=1}^{S}, \Gamma).$$

We first specify $c_0$ such that (4.4) implies:

$$\frac{mT}{kn} \geq \max\left\{ \frac{1}{c_{sb}}, \frac{64}{\alpha} \right\}, \quad \frac{mT}{kn} \geq \frac{8}{\alpha} \left[ 1 + \log\left( \frac{5 \max\{e, c_{sb}\} mT}{kn \mu} \right) \right]. \tag{B.8}$$

Observe that (B.8) implies the condition (B.2) from Lemma B.16 holds. Note that for what follows, we will repeatedly use the inequality $a + b \leq 2 \max\{a, b\}$ for any non-negative $a, b \in \mathbb{R}$.

Since the first condition from (B.8) ensures that $mT/(kn) \geq 16/\alpha$, it is sufficient to replace the second condition from (B.8) with:

$$\frac{mT}{kn} \geq \frac{16}{\alpha} \log\left( \frac{5 \max\{e, c_{sb}\} mT}{kn \mu} \right) = \frac{16}{\alpha} \log\left( \frac{mT}{kn} \right) + \frac{16}{\alpha} \log\left( \frac{5 \max\{e, c_{sb}\}}{\lambda \mu} \right).$$

The condition above is implied by the following sufficient condition:

$$\frac{mT}{kn} \geq \max\left\{ \frac{32}{\alpha} \log\left( \frac{mT}{kn} \right), \frac{64 \log 5}{\alpha}, \frac{64}{\alpha} \log\left( \frac{\max\{e, c_{sb}\}}{\lambda \mu} \right) \right\}.$$  

By Proposition B.2,

$$\frac{mT}{kn} \geq \max\left\{ \frac{128 \log 128}{\alpha}, \frac{128 \log (1/\alpha)}{\alpha} \right\} \implies \frac{mT}{kn} \geq \frac{64}{\alpha} \log\left( \frac{128}{\alpha} \right) \implies \frac{mT}{kn} \geq \frac{32}{\alpha} \log\left( \frac{mT}{kn} \right).$$
Thus, the following is sufficient for (B.8):
\[
\frac{mT}{kn} \geq \max \left\{ \frac{1}{ec_{sb}}, \frac{128 \log 128}{\alpha}, \frac{128 \log (1/\alpha)}{\alpha}, \frac{64}{\alpha} \log \left( \frac{\max\{1, c_{sb}\}}{\mu} \right) \right\}.
\]

The condition above is implied by:
\[
\frac{mT}{kn} \geq \max \left\{ \frac{1}{ec_{sb}}, \frac{128 \log 128}{\alpha}, \frac{128 \log\left(\frac{\max\{1, c_{sb}\}}{\alpha \mu}\right)}{\alpha} \right\}.
\]

Hence we can take \( c_0 = 128 \log 128 \).

By Corollary B.17, we have that \( X_{m,T} \) has full column rank almost surely. Therefore, we can write \( \hat{W}_{m,T} \) as:
\[
\hat{W}_{m,T} = Y_{m,T}^T X_{m,T} (X_{m,T}^T X_{m,T})^{-1}.
\]

Furthermore, we can write \( Y_{m,T} = X_{m,T} W_* + \Xi_{m,T} \). Hence,
\[
\hat{W}_{m,T} - W_* = \Xi_{m,T}^T (X_{m,T}^T X_{m,T})^{-1}.
\]

Put \( \tilde{X}_{m,T} := X_{m,T} \Gamma_{-1/2} \). With this decomposition, we have:
\[
\| \hat{W}_{m,T} - W_* \|_F^2 = \Xi_{m,T}^T (X_{m,T}^T X_{m,T})^{-1} \| F^2 \leq \lambda_{\max}(\Gamma_{-1/2} \Gamma'_{-1/2}) \Xi_{m,T}^T X_{m,T} (X_{m,T}^T X_{m,T})^{-1} \| F^2 \leq \lambda_{\min}(\Gamma_{-1/2} \Gamma'_{-1/2}) \| (\hat{X}_{m,T}^T \tilde{X}_{m,T} - \Xi_{m,T}) \|_2^2 \| \leq \min\{n,p\} \lambda_{\max}(\Gamma_{-1/2} \Gamma'_{-1/2}) \| (\hat{X}_{m,T}^T \tilde{X}_{m,T} - \Xi_{m,T}) \|_2 \| \Xi_{m,T} \|_2 \| \leq \min\{n,p\} \lambda_{\min}(\Gamma_{-1/2} \Gamma'_{-1/2}) \| (\hat{X}_{m,T}^T \tilde{X}_{m,T} - \Xi_{m,T}) \|_2 \| \Xi_{m,T} \|_2 \| \infty \| \Xi_{m,T} \|_2 \| \\leq \lambda_{\min}(\hat{X}_{m,T}^T \hat{X}_{m,T}) \| \frac{\| \hat{X}_{m,T}^T \hat{X}_{m,T} \|_2}{\lambda_{\min}(\hat{X}_{m,T}^T \hat{X}_{m,T})}.
\]

Fix any \( t > 0 \). By Lemma B.16, there exists an event \( \mathcal{E}_{t,1} \) with probability at least \( 1 - 2e^{-t} \), such that on \( \mathcal{E}_{t,1} \) we have:
\[
\text{tr}(\hat{X}_{m,T}^T \hat{X}_{m,T}) \leq \frac{mnt e^t}{\Delta}, \quad \lambda_{\min}(\hat{X}_{m,T}^T \hat{X}_{m,T}) \geq \frac{mT \alpha \mu}{8ec_{sb}} \exp\left(-\frac{16kn}{mT \alpha}\right).
\]

By (B.8), we have \( mT/k \geq 64n/\alpha \). Hence, on \( \mathcal{E}_{t,1} \),
\[
\lambda_{\min}(\hat{X}_{m,T}^T \hat{X}_{m,T}) \geq \zeta_t := \frac{mT \alpha \mu}{8ec_{sb}} \exp(-t/4).
\]

We now apply Proposition B.13 with \( V \leftarrow M_t := \zeta_t I_n \) and:
\[
x_1, \ldots, x_T, x_{T+1}, \ldots, x_{2T}, \ldots, x_{(m-1)T+1}, \ldots, x_{mT} \leftarrow \\
\Gamma_{-1/2} x_1^{(1)}, \ldots, \Gamma_{-1/2} x_T^{(1)}, \Gamma_{-1/2} x_1^{(2)}, \ldots, \Gamma_{-1/2} x_T^{(2)}, \ldots, \Gamma_{-1/2} x_1^{(m)}, \ldots, \Gamma_{-1/2} x_T^{(m)}.
\]

56
to conclude that there exists an event $\mathcal{E}_{t,2}$ with probability at least $1 - e^{-t}$ such that on $\mathcal{E}_{t,2}$:

$$1 \{ \hat{X}_{m,T}^T \hat{X}_{m,T} \succeq M_t \} \| (\hat{X}_{m,T}^T - \hat{X}_{m,T})^{-1/2} \hat{X}_{m,T}^T \Xi_{m,T} \|_\text{op}^2 \leq 16\sigma_\xi^2 \left[ p \log 5 + \frac{1}{2} \log \det \left( I_n + \zeta_t^{-1} \hat{X}_{m,T}^T \hat{X}_{m,T} \right) + t \right]$$

$$\leq 32\sigma_\xi^2 \left[ p + \log \det \left( I_n + \zeta_t^{-1} \hat{X}_{m,T}^T \hat{X}_{m,T} \right) + t \right]$$

$$\leq 32\sigma_\xi^2 \left[ p + n \log (1 + \zeta_t^{-1} \text{tr}(\hat{X}_{m,T}^T \hat{X}_{m,T})/n) + t \right].$$

Above, the last inequality holds since $\log \det(X) \leq n \log(\text{tr}(X)/n)$ for any $X \in \text{Sym}^n_{\geq 0}$ by the AM-GM inequality. By Proposition B.2, whenever $t \geq 8 \log 16$, we have $t \leq e^{t/4}$. Furthermore, for any $t \geq 0$ we have $1 \leq e^{t/4}$. Therefore, for $t \geq 8 \log 16$, on $\mathcal{E}_{t,1} \cap \mathcal{E}_{t,2}$:

$$\frac{\| (\hat{X}_{m,T}^T \hat{X}_{m,T})^{-1/2} \hat{X}_{m,T}^T \Xi_{m,T} \|_\text{op}^2}{\lambda_{\text{min}}(\hat{X}_{m,T}^T \hat{X}_{m,T})} \leq \frac{256 c c_{sb}}{m T \alpha} e^{t/4} \sigma_\xi^2 \left[ p + n \log \left( 1 + \frac{8 c c_{sb}}{\alpha \lambda \mu} e^{(1+1/4)t} \right) + t \right]$$

$$\leq \frac{256 c c_{sb}}{m T \alpha} e^{t/4} \sigma_\xi^2 \left[ p + n \log \left( \frac{16 \max\{1, c_{sb}\}}{\alpha \lambda \mu} \right) + n(1 + 1/4)t + t \right]$$

$$\leq \frac{256 c c_{sb}}{m T \alpha} e^{t/4} \sigma_\xi^2 \left[ p + n \log \left( \frac{16 \max\{1, c_{sb}\}}{\alpha \lambda \mu} \right) + 3nt \right]$$

$$\leq \frac{256 c c_{sb}}{m T \alpha} \sigma_\xi^2 \left[ p + n \log \left( \frac{16 \max\{1, c_{sb}\}}{\alpha \lambda \mu} \right) + 3n \right] e^{t/2}.$$

Define the random variable $Z$ as:

$$Z := \frac{\| (\hat{X}_{m,T}^T \hat{X}_{m,T})^{-1/2} \hat{X}_{m,T}^T \Xi_{m,T} \|_\text{op}^2}{\lambda_{\text{min}}(\hat{X}_{m,T}^T \hat{X}_{m,T})} \left( \frac{256 c c_{sb}}{m T \alpha} \sigma_\xi^2 \left[ p + n \log \left( \frac{16 \max\{1, c_{sb}\}}{\alpha \lambda \mu} \right) + 3n \right] \right)^{-1}.$$

We have shown that:

$$\mathbb{P}(Z > e^{t/2}) \leq 3 e^{-t} \quad \forall t \geq 8 \log 16.$$

Equivalently:

$$\mathbb{P}(Z > s) \leq 3 s^{-2} \quad \forall s \geq 16^4.$$

Hence,

$$\mathbb{E}[Z] = \int_0^\infty \mathbb{P}(Z > s) ds \leq 16^4 + 3 \int_{16^4}^\infty s^{-2} ds = 16^4 + 3/16^4.$$

Therefore, we have shown that for some universal positive $c_1$,

$$\mathbb{E}[\| \hat{W}_{m,T} - W_r \|_F^2] \leq c_1 \sigma_\xi^2 \min\{n, p\} c_{sb} \left[ p + n \log \left( \frac{\max\{c, c_{sb}\}}{\alpha \lambda \mu} \right) \right].$$

(B.9)
Now, if \( p \leq n \), (B.9) is upper bounded by:
\[
c_1 \sigma_x^2 \rho c_{sb} \left[ p + n \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta \mu} \right) \right] \leq 2c_1 \sigma_x^2 \rho c_{sb} \left[ \frac{n \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta \mu} \right)}{mT \Lambda(\Gamma, \Gamma') \mu} \right].
\]

On the other hand, if \( p > n \), (B.9) is upper bounded by:
\[
c_1 \sigma_x^2 n c_{sb} \left[ p + n \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta \mu} \right) \right] < 2c_1 \sigma_x^2 n c_{sb} \left[ \frac{p \log \left( \frac{\max\{e, c_{sb}\}}{\alpha \Delta \mu} \right)}{mT \Lambda(\Gamma, \Gamma') \mu} \right].
\]

\[\square\]

### B.5 Proof of Theorem 4.3

**Theorem 4.3 (Upper bound for Ind-Seq-LS).** There are universal positive constants \( c_0 \) and \( c_1 \) such that the following holds. Fix any sequence of distributions \( \{P_{x,t}\}_{t \geq 1} \), and let \( \Sigma_t := \mathbb{E}_{x \sim P_{x,t}}[x_t x_t'] \) for \( t \in \mathbb{N}_+ \). Suppose there exists \( c_{sb} > 0 \) and \( \alpha \in (0, 1] \) such that for all \( v \in \mathbb{R}^n \setminus \{0\} \), \( \varepsilon > 0 \) and \( t \in \mathbb{N}_+ \):

\[
P_{x_t \sim P_{x,t}} \left\{ (v, x_t)^2 \leq \varepsilon \cdot v^T \Sigma_t v \right\} \leq (c_{sb} \varepsilon)^\alpha.
\]

Furthermore, suppose there exists a \( c_\beta \geq 1 \) and \( \beta > 0 \) such that for all \( s, t \in \mathbb{N}_+ \) satisfying \( s \leq t \):

\[
\frac{1}{\Lambda(\Sigma_s, \Sigma_t)} \leq c_\beta (t/s)^\beta.
\]

If:

\[
n \geq 2, \ mT \geq c_0 n \max \left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \left( \beta + \log \left( \frac{\max\{e, c_{sb}\} c_\beta}{\alpha} \right) \right) \right\},
\]

then, for \( P_x = \otimes_{t \geq 1} P_{x,t} \):

\[
\mathbb{E}[L(\bar{W}_{m,T}^\Gamma; T', P_x)] \leq c_1 c_{sb} \sigma_x^2 c_\beta e^{\beta} \cdot \frac{pm}{mT \alpha} \cdot \phi \left( c_\beta (\beta + 1), (T'/T)\beta \right) \left[ \beta + \log \left( \frac{\max\{e, c_{sb}\} c_\beta}{\alpha} \right) \right].
\]

**Proof.** Equation (4.8) shows that \( P_x \) satisfies the \((T, 1, \{\Sigma_t\}_{t \geq 1}, c_{sb}, \alpha)\)-TrajSB condition. Let \( \Gamma_t := \frac{1}{t} \sum_{k=1}^t \Sigma_k \) for \( t \in \mathbb{N}_+ \). For any \( s, t \in \mathbb{N}_+ \) with \( s \leq t \),

\[
\Lambda(\Sigma_s, \Gamma_t) \geq \Lambda(\Sigma_s, \Sigma_t)
\]

since \( \Gamma_t \preceq \Sigma_t \)

\[
\geq \frac{1}{s} \sum_{k=1}^s \Lambda(\Sigma_k, \Sigma_t)
\]

using Proposition B.3 and Jensen’s inequality

\[
\geq \frac{1}{c_\beta s} \sum_{k=1}^s (k/t)^\beta
\]

using (4.9)

\[
\geq \frac{1}{c_\beta s t^\beta} \left[ 1 + \int_1^s x^\beta dx \right]
\]

since \( x \mapsto x^\beta \) is increasing

\[
= \frac{1}{c_\beta s t^\beta} \frac{s^{\beta+1} + \beta}{\beta + 1} \geq \frac{1}{c_\beta (\beta + 1)} (s/t)^\beta.
\]
Next, recall the inequality $n! \geq (n/e)^n$ for all $n \in \mathbb{N}_+$. The growth condition (4.9) implies that:

$$\mu(\{\Sigma_t\}_{t=1}^T, \Gamma_T) = \left[ \prod_{t=1}^T \Delta(\Sigma_t, \Gamma_T) \right]^{1/T} \geq \left[ \prod_{t=1}^T \Delta(\Sigma_t, \Sigma_T) \right]^{1/T}$$

$$\geq \left[ \prod_{t=1}^T \frac{1}{c_\beta} \left( \frac{t}{T} \right)^\beta \right]^{1/T}$$

$$= \frac{1}{c_\beta T^\beta} \left( T! \right)^{\beta/T}$$

$$\geq \frac{1}{c_\beta T^\beta} \left( T/e \right)^\beta$$

$$= \frac{1}{c_\beta e^\beta}.$$

We now apply Lemma 4.1 with $\Gamma = \Gamma_T$. In doing so, the requirement (4.4) simplifies to:

$$n \geq 2, \quad \frac{mT}{n} \geq c_0 \max \left\{ \frac{1}{c_{sb}}, \frac{1}{\alpha} \log \left( \frac{\max\{e, c_{sb}\} c_\beta e^\beta}{\alpha} \right) \right\}.$$

We first assume that $T' \leq T$, in which case (4.5) yields:

$$\mathbb{E}[L(\hat{W}_{m,T}; T', P_x)] \leq c_1 c_{sb} s_\xi^2 \cdot \frac{pm}{mT\alpha} \cdot c_\beta e^\beta \cdot \log \left( \frac{\max\{e, c_{sb}\} c_\beta e^\beta}{\alpha} \right).$$

On the other hand, when $T' > T$, we have $\Delta(\Gamma_T, \Gamma_{T'}) \geq \frac{1}{c_\beta (\beta + 1)} \left( T'/T \right)^\beta$, and (4.5) yields:

$$\mathbb{E}[L(\hat{W}_{m,T}; T', P_x)] \leq c_1 c_{sb} s_\xi^2 \cdot \frac{pm}{mT\alpha} \cdot c_\beta e^\beta \cdot c_\beta (\beta + 1) \left( \frac{T'}{T} \right)^\beta \cdot \log \left( \frac{\max\{e, c_{sb}\} c_\beta e^\beta}{\alpha} \right).$$

\[\Box\]

### B.6 Proofs for linear dynamical systems

#### B.6.1 Control of ratios of covariance matrices

**Proposition B.18.** Let $(A, B)$ be the dynamics matrices for an LDS-LS instance, and suppose $(A, B)$ satisfy Assumption 4.1, Assumption 4.2, and Assumption 4.3. Put $\Sigma_t := \Sigma_t(A, B)$ for $t \in \mathbb{N}_+$ and $\gamma := \gamma(A, B)$. For any integers $T_1, T_2$ satisfying $1 \leq T_2 \leq T_1$,

$$\lambda_{\min}(\Sigma_{T_2}^{-1/2} \Sigma_{T_1} \Sigma_{T_1}^{-1/2}) \geq \frac{1}{\gamma} \frac{T_2}{T_1}.$$

**Proof.** Observe that for any $t \geq 1$,

$$\Sigma_t = \sum_{k=0}^{t-1} A^k B B^* (A^k)^* = \sum_{k=0}^{t-1} S D^k S^{-1} B B^* S^{-*} (D^k)^* S^*.$$
By Assumption 4.3, we have that $BB^*$ is invertible, and hence $S^{-1}BB^*S^{-*}$ is also invertible. Therefore we have the following lower and upper bound on $\Sigma_t$:

$$\lambda_{\min}(S^{-1}BB^*S^{-*}) \cdot S \left( \sum_{k=0}^{t-1} D^k(D^k)^* \right) S^* \preceq \Sigma_t \preceq \lambda_{\max}(S^{-1}BB^*S^{-*}) \cdot S \left( \sum_{k=0}^{t-1} D^k(D^k)^* \right) S^*.$$  \hspace{1cm} (B.10)

Now recall that for two square matrices $X, Y$, the eigenvalues of $XY$ coincide with the eigenvalues of $YX$. Letting $Q_t := \sum_{k=0}^{t-1} D^k(D^k)^*$, we have:

$$\lambda_{\min}(\Sigma_{T_1}^{-1/2} \Sigma_{T_2} \Sigma_{T_1}^{-1/2}) \geq \lambda_{\min}(S^{-1}BB^*S^{-*}) \lambda_{\min}(\Sigma_{T_1}^{-1/2} SQ_{T_2} S^* \Sigma_{T_1}^{-1/2}) = \lambda_{\min}(S^{-1}BB^*S^{-*}) \lambda_{\min}((SQ_{T_2} S^*)^{1/2} \Sigma_{T_1}^{-1/2} (SQ_{T_2} S^*)^{1/2}) \geq \frac{\lambda_{\min}(S^{-1}BB^*S^{-*})}{\lambda_{\max}(S^{-1}BB^*S^{-*})} (SQ_{T_2} S^*)^{1/2} (S^{-*}Q_{T_1}^{-1} S') (SQ_{T_2} S^*)^{1/2} \frac{\lambda_{\max}(S^{-1}BB^*S^{-*})}{\lambda_{\max}(S^{-1}BB^*S^{-*})} (Q_{T_2} Q_{T_1}^{-1}).$$

Let $\lambda \in \mathbb{C}$ be an eigenvalue of $A$. We have

$$\sum_{k=0}^{t-1} |\lambda|^{2k} = \begin{cases} \frac{1-|\lambda|^{2t}}{1-|\lambda|^2} & \text{if } |\lambda| < 1, \\ t & \text{if } |\lambda| = 1. \end{cases}$$

Therefore, $(Q_{T_2} Q_{T_1}^{-1})_{ii}$ is:

$$(Q_{T_2} Q_{T_1}^{-1})_{ii} = \begin{cases} \frac{1-|\lambda_i|^{2T_2}}{1-|\lambda_i|^{2T_1}} & \text{if } |\lambda_i| < 1, \\ \frac{1-|\lambda_i|^{2T_2}/T_1}{1-|\lambda_i|^{2T_1}} & \text{if } |\lambda_i| = 1. \end{cases}$$

Note that $\inf_{x \in (0,1)} \frac{1-x^2}{1-x} = c$ for $c \in [0,1]$. Therefore, we can lower bound:

$$\lambda_{\min}(Q_{T_2} Q_{T_1}^{-1}) \geq \frac{T_2}{T_1}.$$  

The claim now follows.

\begin{proposition}
Let $(A, B)$ be the dynamics matrices for an LDS-LS instance, and suppose $(A, B)$ satisfy Assumption 4.1, Assumption 4.2, and Assumption 4.3. Put $\Gamma_t := \Gamma_t(A, B)$ for $t \in \mathbb{N}_+$ and $\gamma := \gamma(A, B)$. For any integers $k, t \in \mathbb{N}_+$ satisfying $k \leq t$, we have:

$$\Delta(\Gamma_k, \Gamma_t) \geq \frac{1}{8\gamma} \frac{k}{t}.$$  

Proof. Let $\Sigma_t := \Sigma_t(A, B)$ for $t \in \mathbb{N}_+$. We first consider the case when $k \geq 2$. Observe that $\Gamma_t \preceq \Sigma_t$. Furthermore, for any $k \geq 2$, we have:

$$\Gamma_k = \frac{1}{k} \sum_{k'=1}^{k} \Sigma_{k'} \succeq \frac{1}{k} \sum_{k'=\lceil k/2 \rceil}^{k} \Sigma_{\lfloor k/2 \rfloor} = \frac{k-\lfloor k/2 \rfloor+1}{k} \Sigma_{\lfloor k/2 \rfloor} \succeq \frac{1}{2} \Sigma_{\lfloor k/2 \rfloor}.$$  

\end{proposition}
Therefore,
\[
\lambda(\Gamma_k, \Gamma_t) = \lambda_{\min}(\Gamma_k^{-1/2} \Gamma_t \Gamma_k^{-1/2}) \geq \frac{1}{2} \lambda_{\min}(\Sigma_t^{-1/2} \Sigma_{[k/2]} \Sigma_t^{-1/2}) \geq \frac{1}{2} \frac{|k/2|}{t} \stackrel{(a)}{=} \frac{1}{8} \frac{k}{t}.
\]
Above, (a) follows from Proposition B.18 and (b) follows since \(|k/2| \geq k/4\) by Proposition B.1 since \(k \geq 2\).

Now, we handle the case when \(k = 1\). In this case, \(\Gamma_1 = \Sigma_1\), and therefore by Proposition B.18:
\[
\lambda(\Gamma_1, \Gamma_t) = \lambda(\Sigma_1, \Gamma_t) \geq \lambda(\Sigma_1, \Sigma_t) = \lambda_{\min}(\Sigma_t^{-1/2} \Sigma_1 \Sigma_t^{-1/2}) \geq \frac{1}{2} \frac{1}{t}.
\]
The claim now follows.

Proposition B.20. Let \((A, B)\) be the dynamics matrices for an LDS-LS instance. For any \(s, t \in \mathbb{N}_+\) with \(s \leq t\):
\[
\Gamma_s(A, B) \preceq \Gamma_t(A, B).
\]
Proof. Let \(\Gamma_t := \Gamma_t(A, B)\) and \(\Sigma_t := \Sigma_t(A, B)\) for \(t \in \mathbb{N}_+\). Suppose that \(t > s\), otherwise there is nothing to prove. Now write:
\[
\Gamma_t = \frac{1}{t} \sum_{k=1}^{t} \Sigma_k = \frac{1}{t} \sum_{k=1}^{s} \Sigma_k + \frac{1}{t} \sum_{k=s+1}^{t} \Sigma_k = \frac{s}{t} \Gamma_s + \frac{1}{t} \sum_{k=s+1}^{t} \Sigma_k \geq \frac{s}{t} \Gamma_s + \frac{t-s}{t} \Gamma_s \quad \text{since } \Sigma_{s+\ell} \succeq \Sigma_s \forall \ell \in \mathbb{N}_+
\]
\[
= \Gamma_s.
\]

Proposition B.21. Let \((A, B)\) be the dynamics matrices for an LDS-LS instance, and suppose \((A, B)\) satisfy Assumption 4.1, Assumption 4.2, and Assumption 4.3. Put \(\Gamma_t := \Gamma_t(A, B)\) for \(t \in \mathbb{N}_+\), \(\Sigma_t := \Sigma_t(A, B)\) for \(t \in \mathbb{N}_+\), and \(\gamma := \gamma(A, B)\). For any \(T\), we have:
\[
\left[ \prod_{t=1}^{T} \lambda(\Sigma_t, \Gamma_T) \right]^{1/T} \geq \frac{1}{8e\gamma}.
\]
Proof. By Proposition B.19, we have that \(\lambda(\Gamma_t, \Gamma_T) \geq \frac{1}{8\gamma T}\) for all \(t \in \{1, \ldots, T\}\). Therefore, since \(\lambda(\Sigma_t, \Gamma_T) \geq \lambda(\Gamma_t, \Gamma_T)\), and since \(n! \geq (n/e)^n\) for all \(n \in \mathbb{N}_+\),
\[
\left[ \prod_{t=1}^{T} \lambda(\Sigma_t, \Gamma_T) \right]^{1/T} \geq \left( \frac{T!}{8\gamma T} \right)^{1/T} \geq \frac{1}{8e\gamma}.
\]

\[\square\]
B.6.2 Many trajectory results

Lemma B.22. There are universal positive constants $c_0$ and $c_1$ such that the following holds for any instance of LDS-LS. Suppose that $(A,B)$ is $k_c$-step controllable. If $n \geq 2$ and $m \geq c_0 n$, then for any $\Gamma' \in \text{Sym}_{>0}^n$:

$$
E[\|\hat W_{m,T} - W_*\|^2_{\Gamma'}] \leq c_1 \sigma_\xi^2 \cdot \frac{pm}{mT \cdot \Delta(\Gamma_T(A,B), \Gamma')}.
$$

Proof. Let $\Gamma_T := \Gamma_T(A,B)$. By Example 4.6, LDS-LS satisfies the $(T,T,\Gamma_T,e,1/2)$-TrajSB condition. We therefore invoke Lemma 4.1 with $k = T$ and $\Gamma = \Gamma_T$. In this case, $\mu$ from (4.3) simplifies to $\mu = \Delta(\Gamma_T, \Gamma_T) = 1$, and the requirement (4.4) simplify to $n \geq 2$ and:

$$
\frac{mT}{n} \geq c_0 \max\{e^{-1}, 2 \log(2e)\} = 2c_0 \log(2e).
$$

The rate (4.5) simplifies to:

$$
E[\|\hat W_{m,T} - W_*\|^2_{F}] \leq 2c_1 \sigma_\xi^2 \cdot \frac{pn \log(2e) \cdot mT \cdot \lambda_{\min}(\Gamma_T(A,B))}{mT \cdot \Delta(\Gamma_T, \Gamma')}.
$$

Theorem 4.5 (Parameter recovery upper bound for LDS-LS, many trajectories). There are universal positive constants $c_0$ and $c_1$ such that the following holds for any instance of LDS-LS. Suppose that $(A,B)$ is $k_c$-step controllable. If $n \geq 2$, $m \geq c_0 n$, and $T \geq k_c$, then:

$$
E[\|\hat W_{m,T} - W_*\|^2_{F}] \leq c_1 \sigma_\xi^2 \cdot \frac{pm}{mT \cdot \lambda_{\min}(\Gamma_T(A,B))}.
$$

Proof. Follows by invoking Lemma B.22 with $\Gamma' = I_n$.

Theorem 4.6 (Risk upper bound for LDS-LS, many trajectories). There are universal positive constants $c_0$ and $c_1$ such that the following holds for any instance of LDS-LS. Suppose that $(A,B)$ is $k_c$-step controllable. If $n \geq 2$, $m \geq c_0 n$, $T \geq k_c$, and the evaluation horizon is strict ($T' \leq T$), then:

$$
E[L(\hat W_{m,T}; T', \mathcal{P}_{x}^{A,B})] \leq c_1 \sigma_\xi^2 \cdot \frac{pm}{mT \cdot \gamma T'}.
$$

On the other hand, suppose that $(A,B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma := \gamma(A,B)$ (Definition 4.4). If $n \geq 2$, $m \geq c_0 n$, and the evaluation horizon is extended ($T' > T$), then:

$$
E[L(\hat W_{m,T}; T', \mathcal{P}_{x}^{A,B})] \leq c_1 \sigma_\xi^2 \cdot \frac{pm}{mT \cdot \Delta(\Gamma_T, \Gamma')} \cdot \frac{T'}{T}.
$$

Proof. Let $\Gamma_t := \Gamma_t(A,B)$ for $t \in \mathbb{N}_+$. Invoking Lemma B.22 with $\Gamma' = \Gamma_{T'}$ yields the bound:

$$
E[L(\hat W_{m,T}; T', \mathcal{P}_{x}^{A,B})] \leq c_1 \sigma_\xi^2 \cdot \frac{pm}{mT \cdot \Delta(\Gamma_T, \Gamma')} \cdot \frac{T'}{T}.
$$

If $T' \leq T$, then $\Delta(\Gamma_T, \Gamma_{T'}) \geq 1$ since $\Gamma_T \succeq \Gamma_{T'}$ by Proposition B.20. On the other hand, if $T' > T$, by Proposition B.19, $\Delta(\Gamma_T, \Gamma_{T'}) \geq \frac{1}{8} \frac{T}{T'}$. The claim now follows.
B.6.3 Few trajectory results

**Theorem 4.7** (Risk upper bound for LDS-LS, few trajectories). There are universal positive constants $c_0$, $c_1$, and $c_2$ such that the following holds for any instance of LDS-LS. Suppose that $(A,B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma := \gamma(A,B)$ (Definition 4.4). If $n \geq 2$, $m \leq c_0 n$, and $mT \geq c_1 n \log(\max\{\gamma n/m, e\})$, then:

$$E[L(\hat{W}_{m,T}; T', P^{A,B}_x)] \leq c_2 \sigma^2 \cdot \frac{pn \log(\max\{\gamma n/m, e\})}{mT} \cdot \phi\left(\gamma, \frac{c_1 n \log(\max\{\gamma n/m, e\})}{m} \cdot \frac{T'}{T}\right).$$

**Proof.** Let $\Gamma_t := \Gamma_t(A,B)$ for all $t \in \mathbb{N}_+$. By Example 4.6, for any $k \in \{1, \ldots, T\}$, LDS-LS satisfies the $(T,k,\Gamma_k,e,\frac{1}{2})$-TrajSB condition. We will apply Lemma 4.1 with $\bar{\Gamma} = \bar{\Gamma}_k$. The quantity $\mu$ from (4.3) simplifies to $\mu = \Delta(\bar{\Gamma}_k, \Gamma_k) = 1$. By Proposition B.19, we have that $\Delta(\bar{\Gamma}_k, \Gamma_T) \geq \frac{1}{8\gamma T}$.

Hence the requirement (4.4) simplifies to $n \geq 2$ and:

$$\frac{mT}{kn} \geq c \max\left\{e^{-1}, 2 \log\left(16e\gamma \frac{T}{k}\right)\right\} = 2c \log\left(16e\gamma \frac{T}{k}\right) = 2c \log(16e\gamma) + 2c \log\left(\frac{T}{k}\right), \quad (B.11)$$

for some universal positive constant $c$. Thus, for (B.11) to hold, it suffices to require:

$$\frac{T}{k} \geq \max\left\{\frac{4cn}{m} \log(16e\gamma), \frac{4cn}{m} \log\left(\frac{T}{k}\right)\right\}. \quad (B.12)$$

As long as $4cn/m \geq 1$, then by Proposition B.2,

$$\frac{T}{k} \geq \frac{8cn}{m} \log\left(\frac{16cn}{m}\right) \implies \frac{T}{k} \geq \frac{4cn}{m} \log\left(\frac{T}{k}\right).$$

Hence, for (B.12) to hold, it suffices to require:

$$\frac{T}{k} \geq \max\left\{\frac{4cn}{m} \log(16e\gamma), \frac{8cn}{m} \log\left(\frac{16cn}{m}\right)\right\}, \quad (B.13)$$

for which the following suffices:

$$\frac{T}{k} \geq \frac{8cn}{m} \log\left(\frac{256ec\gamma n}{m}\right). \quad (B.14)$$

Based on (B.14), we choose $k$ as:

$$k = \left\lfloor \frac{T}{8cn/m \cdot \log(256ec\gamma n/m)} \right\rfloor.$$

To ensure that $k \geq 1$, we need to ensure that:

$$mT \geq 8cn \log(256ec\gamma n/m). \quad (B.15)$$

On the other hand, since $4cn/m \geq 1$, we have that:

$$\frac{8cn}{m} \log\left(\frac{256ec\gamma n}{m}\right) \geq 1,$$
The claim now follows. Thus, by taking \( c_0 = 4c \) and \( c_1 = 8c(1 + \log(\max\{256e, 1\})) \), we ensure that (B.11) holds. We now ready to invoke Lemma 4.1 with \( \Gamma' = \Gamma_T \), and conclude:

\[
\mathbb{E}[L(\hat{W}_{m,T}; T', P_{x}^{A,B})] \leq 2c' \sigma_x^2 c_{sb} \cdot \frac{pm \log(2e/\lambda(\Gamma_k, \Gamma_T))}{mT A(\Gamma_k, \Gamma_T)}. \tag{B.16}
\]

First, we assume that \( T' \leq k \). By Proposition B.20 we have \( \Gamma_k \geq \Gamma_{T'} \), and therefore \( \lambda(\Gamma_k, \Gamma_T) \geq 1 \). Equation (B.16) yields:

\[
\mathbb{E}[L(\hat{W}_{m,T}; T', P_{x}^{A,B})] \leq 2c' \sigma_x^2 c_{sb} \cdot \frac{pm \log(2e/\lambda(\Gamma_k, \Gamma_T))}{mT}. \tag{B.17}
\]

By Proposition B.19 and Proposition B.1, \( \lambda(\Gamma_k, \Gamma_T) \geq \frac{1}{8c T} \left[ \frac{T}{8cn/m \cdot \log(256e\gamma n/m)} \right] \geq \frac{m}{128c \gamma n \log(256e\gamma n/m)}. \tag{B.18} \)

Plugging (B.18) into (B.17), and using the inequalities \( \log x \leq x \) for \( x > 0 \) and \( \phi(a, x) \geq 1 \) for all \( a \geq 1 \) yields:

\[
\mathbb{E}[L(\hat{W}_{m,T}; T', P_{x}^{A,B})] \leq 2c' \sigma_x^2 c_{sb} \cdot \frac{pm \log(\max\{\gamma n/m, e\})}{mT} \cdot \phi \left( \gamma, c_1 \frac{n \log(\max\{\gamma n/m, e\})}{m} \frac{T'}{T} \right).
\]

On the other hand, if \( T' > k \), then by Proposition B.19,

\[
\lambda(\Gamma_k, \Gamma_{T'}) \geq \frac{1}{8c T} \left[ \frac{T}{8cn/m \cdot \log(256e\gamma n/m)} \right] \geq \frac{m}{128c \gamma n \log(256e\gamma n/m)} \cdot \frac{T'}{T}. \tag{B.19}
\]

Plugging (B.18) and (B.19) into (B.16) and using again the inequality \( \log x \leq x \) for \( x > 0 \) yields:

\[
\mathbb{E}[L(\hat{W}_{m,T}; T', P_{x}^{A,B})] \leq 2c' \sigma_x^2 c_{sb} \cdot \frac{pm \log(2e \cdot 128c\gamma n/m \cdot \log(256e\gamma n/m))}{mT} \cdot 128c \gamma n/m \cdot \log(256e\gamma n/m) \cdot \frac{T'}{T}
\]

\[
\leq 256c' \sigma_x^2 c_{sb} \cdot \frac{pm \log((256e\gamma n/m)^2)}{mT} \cdot c \gamma n/m \cdot \log(256e\gamma n/m) \cdot \frac{T'}{T}
\]

\[
\leq 512c' (1 + \log(\max\{256e, 1\})) \sigma_x^2 c_{sb} \cdot \frac{pm \log(\max\{\gamma n/m, e\})}{mT} \cdot c \frac{n \log(\max\{\gamma n/m, e\})}{m} \cdot \frac{T'}{T}.
\]

When \( T' > k \), we have that

\[
8c \frac{n \log(256e\gamma n/m)}{m} \frac{T'}{T} > 1 \implies c_1 \frac{n \log(\max\{\gamma n/m, e\})}{m} \frac{T'}{T} > 1
\]

\[
\implies \gamma c_1 \frac{n \log(\max\{\gamma n/m, e\})}{m} \frac{T'}{T} = \phi \left( \gamma, c_1 \frac{n \log(\max\{\gamma n/m, e\})}{m} \frac{T'}{T} \right).
\]

The claim now follows.
Theorem 4.8 (Risk upper bound for Ind-LDS-LS). There are universal positive constants $c_0$, $c_1$, and $c_2$ such that the following holds for any instance of Ind-LDS-LS. Suppose that $(A, B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma := \gamma(A, B)$ (Definition 4.4). If $n \geq 2$ and $mT \geq c_1 n \log(\max\{\gamma, e\})$, then:

$$
\mathbb{E}[L(\hat{W}_{m,T}; T', \otimes_{t \geq 1} P_{A,B}^{t,A,B})] \leq c_2 \sigma_\xi^2 \cdot \frac{pm \log(\max\{\gamma, e\})}{mT} \cdot \phi\left(\gamma, \frac{T'}{T}\right).
$$

Proof. Let $\Gamma_t := \Gamma_t(A, B)$ and $\Sigma_t := \Sigma_t(A, B)$ for $t \in \mathbb{N}_+$. From Example 4.3, we have that Ind-LDS-LS satisfies the $(T, 1, \{\Sigma_t\}_{t=1}^T, e, 1/2)$-TrajSB condition. We will apply Lemma 4.1 with $\Gamma = \Gamma_T$, $k = 1$, and $\Gamma' = \Gamma_{T'}$. By Proposition B.21, we have that:

$$
\mu(\{\Sigma_t\}_{t=1}^T, \Gamma_T) \geq \frac{1}{8e\gamma}.
$$

The requirement (4.4) simplifies to $n \geq 2$ and:

$$
\frac{mT}{n} \geq c_0 2 \log(16e^2\gamma).
$$

By Lemma 4.1,

$$
\mathbb{E}[L(\hat{W}_{m,T}; T', P_{A,B}^{t,A,B})] \leq 2c_1 \sigma_\xi^2 e \cdot \frac{pn \log(16e^2\gamma)}{mT} \cdot \phi\left(\gamma, \frac{T'}{T}\right).
$$

If $T' \leq T$, then $\Lambda(\Gamma_T, \Gamma_{T'}) \geq 1$ since $\Gamma_T \geq \Gamma_{T'}$ by Proposition B.20. On the other hand, if $T' > T$, then by Proposition B.19, $\Lambda(\Gamma_T, \gamma_{T'}) \geq \frac{1}{8e\gamma_0}$. The claim now follows. \hfill \Box

Theorem 4.9 (Parameter recovery upper bound for LDS-LS, few trajectories). There are universal positive constants $c_0$, $c_1$, $c_2$, and $c_3$ such that the following holds for any instance of LDS-LS. Suppose that $(A, B)$ satisfies Assumption 4.1, Assumption 4.2, and Assumption 4.3, with $\gamma := \gamma(A, B)$ (Definition 4.4). If $n \geq 2$, and $mT \geq c_1 n \log(\max\{\gamma n/m, e\})$, then:

$$
\mathbb{E}[\|\hat{W}_{m,T} - W_\star\|_F^2] \leq c_2 \sigma_\xi^2 \cdot \frac{pm \log(\max\{\gamma n/m, e\})}{mT \cdot \lambda_{\text{min}}(\Gamma_{k, (A, B)})^2},
$$

where $k_\star := \left\lfloor \frac{c_3 T}{n/m \cdot \log(\max\{\gamma n/m, e\})} \right\rfloor$.

Proof. The proof is identical to that of Theorem 4.7 until (B.16), after which we set $T' = 1$ from which the result follows. \hfill \Box

C Analysis for lower bounds

C.1 Preliminaries

Here, we collect the necessary auxiliary results we will use to prove the lower bound. Our first result is an instance of the well-known fact that the conditional mean is the estimator which minimizes the mean squared error.
Proposition C.1. Let $T \in \mathbb{N}_+$ and $\{P_{x,t}\}_{t=1}^T$ be a sequence of distributions over $\mathbb{R}^n$ with finite second moments $\Sigma_t := \mathbb{E}_{x_t \sim P_{x,t}}[x_t x_t^T]$. Let $P_W$ be any arbitrary distribution on $\mathbb{R}^{p \times n}$. Put $\Gamma_T := \frac{1}{T} \sum_{t=1}^T \Sigma_t$. We have:

$$
\inf_{W} \mathbb{E}_{W \sim P_W} \left[ \sum_{t=1}^T \mathbb{E}_{x_t \sim P_{x,t}} \left| \mathbb{E}(\hat{W}(x_t) - W x_t)^2 \right| \right] = \mathbb{E}_{W \sim P_W} \left( \mathbb{E}_{W' \sim P_W} [W'] - W \right)^2_{\Gamma_T},
$$

where the infimum ranges over measurable functions $\hat{W} : \mathbb{R}^n \to \mathbb{R}^p$.

Proof. Let $\mu_T := \frac{1}{T} \sum_{t=1}^T P_{x,t}$ denote the uniform mixture distribution, so that

$$
\frac{1}{T} \sum_{t=1}^T \mathbb{E}_{x_t \sim P_{x,t}} \left| \mathbb{E}(\hat{W}(x_t) - W x_t)^2 \right| = \mathbb{E}_{\hat{x}, \mu_T} \left( \mathbb{E}(\hat{W}(\hat{x}) - W \hat{x})^2 \right).
$$

By repeated applications of Fubini’s theorem,

$$
\inf_{W} \mathbb{E}_{W \sim P_W} \mathbb{E}_{\hat{x} \sim \mu_T} \left| \mathbb{E}(\hat{W}(\hat{x}) - W \hat{x})^2 \right| = \inf_{W} \mathbb{E}_{\hat{x} \sim \mu_T} \mathbb{E}_{W \sim P_W} \mathbb{E}(\hat{W}(\hat{x}) - W \hat{x})^2
$$

$$
= \mathbb{E}_{\hat{x} \sim \mu_T} \left[ \inf_{\hat{y} \in \mathbb{R}^p} \mathbb{E}_{W \sim P_W} \left( \hat{y} - W \hat{x} \right)^2 \right]
$$

$$
= \mathbb{E}_{\hat{x} \sim \mu_T} \mathbb{E}_{W \sim P_W} \mathbb{E}_{W' \sim P_W} \left| W' \hat{x} - W \hat{x} \right|^2
$$

$$
= \mathbb{E}_{W \sim P_W} \mathbb{E}_{\hat{x} \sim \mu_T} \mathbb{E}_{W' \sim P_W} \left| W' \hat{x} - W \hat{x} \right|^2
$$

$$
= \mathbb{E}_{W \sim P_W} \mathbb{E}_{W' \sim P_W} \left| W' - W \right|^2_{\Gamma_T},
$$

where the last equality holds since for any size conforming matrix $M$,

$$
\mathbb{E}_{\hat{x} \sim \mu_T} \left( \mathbb{E}(\hat{x})^2 \right) = \frac{1}{T} \sum_{t=1}^T \mathbb{E}_{x_t \sim P_{x,t}} \left( M x_t \right)^2 = \frac{1}{T} \sum_{t=1}^T \text{tr}(M \Sigma_t M^T)
$$

$$
= \text{tr} \left( M \left[ \frac{1}{T} \sum_{t=1}^T \Sigma_t \right] M^T \right) = \|M\|^2_{\Gamma_T}.
$$

\[ \square \]

The next result is a simple fact which states that if a function is strictly increasing and concave on an interval, then any root of the function is lower bounded by the root of the linear approximation at any point in the interval.

Proposition C.2. Let $f : I \to \mathbb{R}$ be a $C^1(I)$ function that is strictly increasing and concave on an interval $I \subseteq \mathbb{R}$. Suppose that $f$ has a (unique) root $x_0 \in I$. For any $x \in I$, we have that:

$$
\frac{x - f(x)}{f'(x)} \leq x_0.
$$

Proof. Because $f$ is concave on $I$, we have that:

$$
0 = f(x_0) \leq f(x) + f'(x_0)(x_0 - x).
$$

Next, because $f$ is strictly increasing on $I$, we have that $f'(x) > 0$. The claim now follows by re-arranging the previous inequality. \[ \square \]
The next result states that the trace inverse of any positive definite matrix is lower bounded by the trace inverse of any principle submatrix. The claim is immediate from Cauchy’s eigenvalue interlacing theorem, but we give a more direct proof.

**Proposition C.3.** Let \( M \in \mathbb{R}^{q \times n} \) have full column rank. Let \( I \subseteq \{1, ..., n\} \) be any index set, and let \( E_I : \mathbb{R}^n \to \mathbb{R}^{|I|} \) denote any linear map which extracts the coordinates associated to \( I \). We have:

\[
\text{tr}((M^T M)^{-1}) \geq \text{tr}((E_I M^T M E_I^T)^{-1}).
\]

**Proof.** Fix a \( z \in \mathbb{R}^n \). Since \( M \) has full column rank, we have that \((M^T)^\dagger = M(M^T)^{-1}\). Therefore,

\[
\min_{c \in \mathbb{R}^q : M^T c = z} \|c\|_2^2 = \|(M^T)^\dagger z\|_2^2 = z^T (M^T M)^{-1} z.
\]

Taking expectation with \( z \sim N(0, I_n) \),

\[
\text{tr}((M^T M)^{-1}) = \mathbb{E}_{z \sim N(0, I_n)} \left[ \min_{c \in \mathbb{R}^q : M^T c = z} \|c\|_2^2 \right].
\]

On the other hand, we have that:

\[
\min_{c \in \mathbb{R}^q : M^T c = z} \|c\|_2^2 \geq \min_{c \in \mathbb{R}^q : E_I M^T c = E_I z} \|c\|_2^2.
\]

This is clear because for any \( c \in \mathbb{R}^q \) satisfying \( M^T c = z \), the equality \( E_I M^T c = E_I z \) trivially holds. This means we have the following set inclusion:

\[
\{ c \in \mathbb{R}^q : M^T c = z \} \subseteq \{ c \in \mathbb{R}^q : E_I M^T c = E_I z \}.
\]

Therefore, minimizing any function over the first set will be lower bounded by minimizing the same function over the second set. From this inclusion, we conclude for any index set \( I \):

\[
\text{tr}((M^T M)^{-1}) = \mathbb{E}_{z \sim N(0, I_n)} \left[ \min_{c \in \mathbb{R}^q : M^T c = z} \|c\|_2^2 \right] \geq \mathbb{E}_{z \sim N(0, I_n)} \left[ \min_{c \in \mathbb{R}^q : E_I M^T c = E_I z} \|c\|_2^2 \right] = \mathbb{E}_{z \sim N(0, I_I)} \left[ \min_{c \in \mathbb{R}^q : E_I M^T c = E_I z} \|c\|_2^2 \right] = \text{tr}((E_I M^T M E_I^T)^{-1}).
\]

\[ \square \]

Next, we state well-known upper and lower tail bounds for chi-squared random variables.

**Lemma C.4 (Laurent and Massart (2000, Lemma 1)).** Let \( g_1, ..., g_D \) be iid \( N(0, 1) \) random variables, and let \( a_1, ..., a_D \) be non-negative scalars. For any \( t > 0 \), we have:

\[
\mathbb{P} \left\{ \sum_{i=1}^D a_i (g_i^2 - 1) \geq 2 \sqrt{t} \left( \sum_{i=1}^D a_i^2 + 2t \max_{i=1, ..., D} a_i \right) \right\} \leq e^{-t},
\]

\[
\mathbb{P} \left\{ \sum_{i=1}^D a_i (g_i^2 - 1) \leq -2 \sqrt{t} \left( \sum_{i=1}^D a_i^2 \right) \right\} \leq e^{-t}.
\]

67
Finally, we conclude with a convex extension of Gordon’s min-max theorem.

**Theorem C.5** (Thrampoulidis et al. (2014, Theorem II.1)). Let $A \in \mathbb{R}^{m \times n}$, $g \in \mathbb{R}^m$, and $h \in \mathbb{R}^n$ have iid $N(0, 1)$ entries and be independent of each other. Suppose that $S_1 \subseteq \mathbb{R}^n$ and $S_2 \subseteq \mathbb{R}^m$ are non-empty compact convex sets, and let $\psi : S_1 \times S_2 \to \mathbb{R}$ be a continuous, convex-concave function. For every $t \in \mathbb{R}$, we have:

$$
\mathbb{P}\left\{ \min_{x\in S_1} \max_{y\in S_2} \left[ y^T A x + \psi(x, y) \right] \geq t \right\} \leq 2\mathbb{P}\left\{ \min_{x\in S_1} \max_{y\in S_2} \left[ \|x\|_2 g^T y + \|y\|_2 h^T x + \psi(x, y) \right] \geq t \right\}.
$$

C.2 Proof of Lemma 5.1

We first prove the following intermediate result, which holds under the Gaussian observation noise model (Definition 6.1).

**Lemma C.6.** Let $T \in \mathbb{N}_+$, $\{P_{x,t}\}_{t=1}^T$ be a sequence of distributions over $\mathbb{R}^n$ with finite second moments $\Sigma_t := \mathbb{E}_{x_t \sim P_{x,t}}[x_t x_t^T]$, and $\sigma^2 > 0$. Let $P_X$ be a distribution on $\mathbb{R}^{q \times n}$ with $q \geq n$ such that for $X \sim P_X$, $X^T X$ is invertible almost surely. For $W \in \mathbb{R}^{p\times q}$, let $P_W$ be the distribution over $\mathbb{R}^{q \times n} \times \mathbb{R}^{q \times p}$ with $(X, Y) \sim P_W$ satisfying $X \sim P_X$ and $Y | X = XW^T + \Xi$, where $\Xi \in \mathbb{R}^{q \times p}$ has iid $N(0, \sigma^2 I)$ entries (and is independent of everything else). Put $\Gamma_T := \frac{1}{T} \sum_{t=1}^T \Sigma_t$. We have that:

$$
\inf_{W} \sup_{W \in \mathbb{R}^{p\times q}} \mathbb{E}_{(X, Y) \sim P_W} \mathbb{E}_{(x, y) \sim P_{x,t}} \left[ \frac{1}{T} \sum_{t=1}^T \mathbb{E}_{x_t \sim P_{x,t}} \|\hat{W}(X, Y, x_t) - W x_t\|_2^2 \right] 
\geq \sigma^2 p \cdot \mathbb{E}_{X \sim P_X} \text{tr}(\Gamma_T^{1/2} (X^T X)^{-1} \Gamma_T^{1/2}),
$$

where the infimum ranges over all measurable functions $\hat{W} : \mathbb{R}^{q \times n} \times \mathbb{R}^{q \times p} \times \mathbb{R}^n \to \mathbb{R}^p$.

**Proof.** This proof is heavily inspired by the proof of Mourtada (2019, Theorem 1). Let $p_{\lambda}$ be any prior distribution over $\mathbb{R}^{p\times n}$. Let $\mu_T := \frac{1}{T} \sum_{t=1}^T P_{x,t}$ denote the uniform mixture. Bounding the minimax risk from below by the Bayes risk:

$$
\inf_{W} \sup_{W \in \mathbb{R}^{p\times q}} \mathbb{E}_{(X, Y) \sim P_W} \mathbb{E}_{x \sim \mu_T} \|\hat{W}(X, Y, x) - W \tilde{x}\|_2^2 
\geq \inf_{W} \mathbb{E}_{W_{\lambda} \sim P_{\lambda}} \mathbb{E}_{(X, Y) \sim P_{W_{\lambda}}} \mathbb{E}_{x \sim \mu_T} \|\hat{W}(X, Y, x) - W_{\lambda} \tilde{x}\|_2^2
$$

$$
= \inf_{W} \mathbb{E}_{(X, Y)} \mathbb{E}_{W_{\lambda}(X, Y)} \mathbb{E}_{x \sim \mu_T} \|\hat{W}(X, Y, x) - W_{\lambda} \tilde{x}\|_2^2
$$

$$
= \mathbb{E}_{(X, Y)} \inf_{W_{X,Y}} \mathbb{E}_{W_{\lambda}(X, Y)} \|\hat{W}_{X,Y}(\tilde{x}) - W_{\lambda} \tilde{x}\|_2^2
$$

$$
= \mathbb{E}_{(X, Y)} \mathbb{E}_{W_{\lambda}(X, Y)} \mathbb{E}_{W_{X,Y}} \|W_{\lambda} - W_{\lambda} \|_2^2
$$

using Fubini’s theorem

Now let $W_{\lambda} \sim p_{\lambda}$ have iid $N(0, 1/\lambda)$ entries for $\lambda > 0$. Noting that

$$
\text{vec}(Y) = (I_p \otimes X) \text{vec}(W_{\lambda}^T) + \text{vec}(\Xi),
$$

we have the vector

$$
\begin{bmatrix}
\text{vec}(W_{\lambda}^T) \\
\text{vec}(Y)
\end{bmatrix}
| X \text{ is jointly Gaussian. Specifically,}
$$

$$
\begin{bmatrix}
\text{vec}(W_{\lambda}^T) \\
\text{vec}(Y)
\end{bmatrix}
| X \sim N \left( 0, \begin{bmatrix}
\frac{1}{\lambda} I_p & \frac{1}{\lambda} (I_p \otimes X^T) \\
\frac{1}{\lambda} (I_p \otimes XX^T) & \sigma^2 I_{p^2}
\end{bmatrix} \right).
$$

68
Therefore, the distribution of vec($W^T_\lambda$) | $X, Y$ is:

$$
vec(W^T_\lambda) | X, Y \sim N(\mu_\lambda, \Sigma_\lambda),
$$

$$
\mu_\lambda := \frac{1}{\lambda} (I_p \otimes X^T) \left[ \frac{1}{\lambda} (I_p \otimes XX^T) + \sigma_\xi^2 I_{qp} \right]^{-1} \text{vec}(Y),
$$

$$
\Sigma_\lambda := \frac{1}{\lambda^2} I_{pn} - \frac{1}{\lambda^2} (I_p \otimes X^T) \left[ \frac{1}{\lambda} (I_p \otimes XX^T) + \sigma_\xi^2 I_{qp} \right]^{-1} (I_p \otimes X).
$$

A simple generalization of the algebraic identity $X^T(\frac{1}{\lambda} XX^T + \sigma_\xi^2 I_q)^{-1} = (\frac{1}{\lambda} X^TX + \sigma_\xi^2 I_n)^{-1}X^T$ yields the identity:

$$
(I_p \otimes X^T) \left[ \frac{1}{\lambda} (I_p \otimes XX^T) + \sigma_\xi^2 I_{qp} \right]^{-1} = \left[ \frac{1}{\lambda} (I_p \otimes X^TX) + \sigma_\xi^2 I_{np} \right]^{-1} (I_p \otimes X^T).
$$

Therefore,

$$
\mathbb{E}[\text{vec}(W^T_\lambda) | X, Y] - \text{vec}(W^T_\lambda)
$$

$$
= \mu_\lambda - \text{vec}(W^T_\lambda)
$$

$$
= \left[ (I_p \otimes X^T X) + \sigma_\xi^2 \lambda I_{np} \right]^{-1} (I_p \otimes X^T \text{vec}(Y) - \text{vec}(W^T_\lambda))
$$

$$
= \left[ (I_p \otimes X^T X) + \sigma_\xi^2 \lambda I_{np} \right]^{-1} (I_p \otimes X^T X) - I_{np} \text{vec}(W^T_\lambda)
$$

$$
+ \left[ (I_p \otimes X^T X) + \sigma_\xi^2 \lambda I_{np} \right]^{-1} (I_p \otimes X^T \text{vec}(\Xi)).
$$

Observing that

$$
||\mathbb{E}[W_\lambda | X, Y] - W_\lambda||^2_{\Gamma_T} = ||\mathbb{E}[\text{vec}(W^T_\lambda) | X, Y] - \text{vec}(W^T_\lambda)||^2_{I_p \otimes \Gamma_T},
$$

and defining $M_X(\lambda) := (I_p \otimes X^T X) + \sigma_\xi^2 \lambda I_{np}$, we have that:

$$
\mathbb{E}_X,\Xi, W_\lambda ||\mathbb{E}[W_\lambda | X, Y] - W_\lambda||^2_{\Gamma_T}
$$

$$
= \mathbb{E}_X,\Xi, W_\lambda \left[ \left[ M_X^{-1}(\lambda)(I_p \otimes X^T X) - I_{np} \right] \text{vec}(W^T_\lambda) \right]^2_{I_p \otimes \Gamma_T}
$$

$$
+ \sigma_\xi^2 \mathbb{E}_X \text{tr} \left( (I_p \otimes \Gamma_T^{1/2}) M_X^{-1}(\lambda)(I_p \otimes X^T X) M_X^{-1}(\lambda)(I_p \otimes \Gamma_T^{1/2}) \right)
$$

$$
\geq \sigma_\xi^2 \mathbb{E}_X \text{tr} \left( (I_p \otimes \Gamma_T^{1/2}) M_X^{-1}(\lambda)(I_p \otimes X^T X) M_X^{-1}(\lambda)(I_p \otimes \Gamma_T^{1/2}) \right).
$$

Since $\lambda \mapsto \text{tr} \left( (I_p \otimes \Gamma_T^{1/2}) M_X^{-1}(\lambda)(I_p \otimes X^T X) M_X^{-1}(\lambda)(I_p \otimes \Gamma_T^{1/2}) \right)$ is decreasing in $\lambda$ for $\lambda > 0$, by the monotone convergence theorem, we have that:

$$
\lim_{\lambda \to 0^+} \mathbb{E}_X \text{tr} \left( (I_p \otimes \Gamma_T^{1/2}) M_X^{-1}(\lambda)(I_p \otimes X^T X) M_X^{-1}(\lambda)(I_p \otimes \Gamma_T^{1/2}) \right)
$$

$$
= \mathbb{E}_X \text{tr} \left( (I_p \otimes \Gamma_T^{1/2}) M_X^{-1}(0)(I_p \otimes X^T X) M_X^{-1}(0)(I_p \otimes \Gamma_T^{1/2}) \right)
$$

$$
= \mathbb{E}_X \text{tr} \left( (I_p \otimes \Gamma_T^{1/2})(X^T X)^{-1} \Gamma_T^{1/2} \right)
$$

$$
= p \cdot \mathbb{E}_X \text{tr}(\Gamma_T^{1/2} (X^T X)^{-1} \Gamma_T^{1/2}).
$$

69
Hence,
\[ \mathbb{E}_{X \in \mathcal{W}_{\lambda}} \| \mathbb{E}[W_{\lambda} \mid X, Y] - W_{\lambda} \|_{F}^{2} \geq \sigma_{\xi}^{2} \rho \cdot \mathbb{E}_{X} \text{tr}((\Gamma_{T}^{1/2}(X^{T}X)^{-1} \Gamma_{T}^{1/2})), \]
which concludes the proof. \(\square\)

We now restate and prove Lemma 5.1.

**Lemma 5.1** (Expected trace of inverse covariance bounds risk from below). Fix \(m, T \in \mathbb{N}_{+}\) and a set of covariate distributions \(\mathcal{P}_{x}\). Suppose that for every \(\mathcal{P}_{x} \in \mathcal{P}_{x}\), the data matrix \(X_{m,T} \in \mathbb{R}^{m \times n}\) drawn from \(\otimes_{i=1}^{m} \mathcal{P}_{x}\) has full column rank almost surely. The minimax risk \(R(m, T, T'; \mathcal{P}_{x})\) satisfies:

\[ R(m, T, T'; \mathcal{P}_{x}) \geq \sigma_{\xi}^{2} \rho \cdot \sup_{\mathcal{P}_{x} \in \mathcal{P}_{x}} \mathbb{E}_{i=1}^{m} \left[ \text{tr}\left( \Gamma_{T'}^{1/2}(P_{x})(X_{m,T}^{T}X_{m,T})^{-1} \Gamma_{T'}^{1/2}(P_{x}) \right) \right] . \]

**Proof.** Fix \(\mathcal{P}_{x} \in \mathcal{P}_{x}\), and let \(\{P_{x,t}\}_{t=1}^{T'}\) denote its marginal distributions up to time \(T'\). Let \(P_{x}^\#\) denote the \(\sigma_{\xi}\)-MDS corresponding to the Gaussian observation noise model (Definition 6.1). Note that for any hypothesis \(f : \mathbb{R}^{n} \rightarrow \mathbb{R}^{p}\), we have from (3.2):

\[ L(\hat{f} ; T', \mathcal{P}_{x}) = \mathbb{E}_{P_{x}} \left[ \frac{1}{T'} \sum_{t=1}^{T'} \| \hat{f}(x_{t}) - W_{*}x_{t} \|_{2}^{2} \right] = \frac{1}{T'} \sum_{t=1}^{T'} \mathbb{E}_{x_{t} \sim P_{x,t}} \| \hat{f}(x_{t}) - W_{*}x_{t} \|_{2}^{2} . \]

By the definition of \(R(m, T, T'; \mathcal{P}_{x})\) from (3.5) and Lemma C.6:

\[ R(m, T, T'; \mathcal{P}_{x}) \geq \inf \sup_{\text{Alg}\{W_{x}\}} \mathbb{E}_{i=1}^{m} \left[ L \left( \text{Alg}\{((x_{i}^{(j)}, y_{i}^{(j)}))_{i=1}^{m,T}; T', \mathcal{P}_{x}) \right) \right] \geq \sigma_{\xi}^{2} \rho \cdot \sup_{\mathcal{P}_{x} \in \mathcal{P}_{x}} \left[ \text{tr}\left( \Gamma_{T'}^{1/2}(P_{x})(X_{m,T}^{T}X_{m,T})^{-1} \Gamma_{T'}^{1/2}(P_{x}) \right) \right] . \]

Since the bound above holds for any \(\mathcal{P}_{x} \in \mathcal{P}_{x}\), we can take the supremum over \(\mathcal{P}_{x} \in \mathcal{P}_{x}\), from the which the claim follows. \(\square\)

**C.3 A general risk lower bound**

We now state a lower bound which applies with an arbitrary number of trajectories.

**Lemma C.7.** Suppose that \(\mathcal{P}_{x}\) is any set containing \(P_{x}^{0m \times n}\) and \(P_{x}^{I_{n}}\). Let \(mT \geq n\). Then:

\[ R(m, T, T'; \mathcal{P}_{x}) \geq \sigma_{\xi}^{2} \frac{1}{2} \cdot \frac{m}{mT} \cdot \max \left\{ \frac{T'}{T}, 1 \right\} . \]

**Proof.** Define \(\zeta(A) := \mathbb{E}_{i=1}^{m} P_{x}^{\#} \left[ \text{tr}\left( \Gamma_{T'}^{1/2}(A)(X_{m,T}^{T}X_{m,T})^{-1} \Gamma_{T'}^{1/2}(A) \right) \right] . \) By Lemma 5.1:

\[ R(m, T, T'; \mathcal{P}_{x}) \geq \sigma_{\xi}^{2} \rho \cdot \max \{ \zeta(0_{m \times n}), \zeta(I_{n}) \} . \tag{C.1} \]

Next, for any \(M \in \text{Sym}_{\geq 0}^{n}\), the function \(X \mapsto \text{tr}(M^{1/2}X^{-1}M^{1/2})\) is convex on the domain \(\text{Sym}_{\geq 0}^{n}\). To see this, we define \(f(X; v) := v^{T}X^{-1}v\) for \(X \in \text{Sym}_{\geq 0}^{n}\). We can write \(f(X; v)\) as \(f(X; v) = \sup \{ -z^{T}Xz + 2v^{T}z \mid z \in \mathbb{R}^{n} \};\) therefore \(X \mapsto f(X; v)\) is convex on \(\text{Sym}_{\geq 0}^{n}\), since it is the pointwise supremum of an affine function in \(X\). Now we see that \(X \mapsto \text{tr}(M^{1/2}X^{-1}M^{1/2})\)
is convex, since $\text{tr}(M^{1/2}X^{-1}M^{1/2}) = \sum_{i=1}^{n} f(X; M^{1/2}e_{i})$, which is the sum of convex functions. Therefore by Jensen’s inequality, whenever $X_{m,T}^{T}X_{m,T}$ is invertible almost surely,

$$\zeta(A) = \mathbb{E}_{\otimes_{i=1}^{n} P_{\mathcal{F}_{i}}} \left[ \text{tr} \left( \Gamma_{\mathcal{F}_{i}}^{1/2}(A)(X_{m,T}^{T}X_{m,T})^{-1}\Gamma_{\mathcal{F}_{i}}^{1/2}(A) \right) \right]$$

$$\geq \text{tr} \left( \Gamma_{\mathcal{F}_{i}}^{1/2}(A)(\mathbb{E}_{\otimes_{i=1}^{n} P_{\mathcal{F}_{i}}} [X_{m,T}^{T}X_{m,T}])^{-1}\Gamma_{\mathcal{F}_{i}}^{1/2}(A) \right)$$

$$= \text{tr} \left( \Gamma_{\mathcal{F}_{i}}^{1/2}(A)(mT \cdot \Gamma_{\mathcal{F}_{i}}(A))^{-1}\Gamma_{\mathcal{F}_{i}}^{1/2}(A) \right)$$

$$= \frac{\text{tr}(\Gamma_{\mathcal{F}_{i}}(A)\Gamma_{\mathcal{F}_{i}}^{-1}(A))}{mT}.$$ 

We first consider the case when $A = 0_{n \times n}$. Under these dynamics, it is a standard fact that when $mT \geq n$, then $X_{m,T}^{T}X_{m,T}$ is invertible almost surely. Furthermore, $\Gamma_{\mathcal{F}_{i}}(0_{n \times n}) = I_{n}$ for all $t$, Hence, $\zeta(0_{n \times n}) \geq \frac{n}{mT}$.

Next, we consider the case when $A = I_{n}$. We first argue that as long as $mT \geq n$, the matrix $X_{m,T}^{T}X_{m,T}$ is invertible almost surely. We write $x^{(i)}_{t} = \sum_{k=1}^{t} w^{(i)}_{k}$, where $\{w^{(i)}_{k}\}_{k=1}^{mT}$ are all iid $N(0, I_{n})$ vectors. Let $p : \mathbb{R}^{mTn} \rightarrow \mathbb{R}$ be the polynomial $p(\{w^{(i)}_{k}\}) = \det(X_{m,T}^{T}X_{m,T})$. The zero-set of $p$ is either all of $\mathbb{R}^{mTn}$, or Lebesgue measure zero. We will select $\{w^{(i)}_{k}\}$ so that $p(\{w^{(i)}_{k}\}) \neq 0$, which shows that the zeros of this polynomial are not all of $\mathbb{R}^{mTn}$, and hence Lebesgue measure zero. Since the Gaussian measure on $\mathbb{R}^{mTn}$ is absolutely continuous w.r.t. the Lebesgue measure on $\mathbb{R}^{mTn}$, this implies that $\det(X_{m,T}^{T}X_{m,T}) \neq 0$ almost surely.

To select $\{w^{(i)}_{k}\}$, we introduce some notation. Let $e_{i} \in \mathbb{R}^{n}$ denote the $i$-th standard basis vector. For any positive integer $k$, let $U(k) \in \mathbb{R}^{k \times k}$ be the upper triangular matrix with ones for all its non-zero entries. Let $S(k) = U(k)U(k)^{T}$. By construction, $S(k)$ is invertible since $U(k)$ is invertible. We put $w^{(i)}_{t} = e_{(i-1)t+1} \cdot 1\{(i-1)T + t \leq n\}$. We now claim that with this choice of $\{w^{(i)}_{t}\}$, the matrix $X_{m,T}^{T}X_{m,T}$ is invertible.

Suppose first that $T \geq n$. Then we have that $X_{m,T}^{T}X_{m,T} = S(n)$, and therefore $\det(X_{m,T}^{T}X_{m,T}) \neq 0$ On the other hand, suppose that $T < n$. Because $mT \geq n$, then we have that:

$$X_{m,T}^{T}X_{m,T} = \text{BDiag}(S(T), ..., S(T), S(n - T[n/T])),$$

where $\text{BDiag}(M_{1}, ..., M_{k})$ denotes the block diagonal matrices with block diagonals $M_{1}, ..., M_{k}$. Since $S(T)$ and $S(n - T[n/T])$ are both invertible, so is $X_{m,T}^{T}X_{m,T}$ and therefore $\det(X_{m,T}^{T}X_{m,T}) \neq 0$. Thus, $X_{m,T}^{T}X_{m,T}$ is invertible almost surely.

Next, we note that $\Sigma_{t}(I_{n}) = t \cdot I_{n}$ and $\Gamma_{t}(I_{n}) = \left(\frac{1}{2} \sum_{k=1}^{t} k\right) \cdot I_{n} = \frac{t+1}{2} \cdot I_{n}$. Hence we have $\Gamma_{T}(I_{n})\Gamma_{T}^{-1}(I_{n}) = \frac{T'}{T+1} \cdot I_{n} \succ \frac{T'}{2T} \cdot I_{n}$, and therefore $\zeta(I_{n}) \geq \frac{n}{2mT} \cdot \frac{T'}{T}$. Combining our bounds on $\zeta(0_{n \times n})$ and $\zeta(I_{n})$, we have the desired claim:

$$R(m, T, T', \mathcal{F}_{i}) \geq \sigma^{2}_{\xi} p \cdot \max \left\{ \frac{n}{mT}, \frac{n}{2mT} \cdot \frac{T'}{T} \right\} \geq \frac{\sigma^{2}_{\xi}}{2} \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{T'}{T}, 1 \right\}.$$ 

□
C.4 Non-isotropic random gramian matrices

The goal of this subsection is to prove Lemma 6.1, which gives a bound on the expected trace inverse of a non-isotropic random gramian matrix. We first prove an auxiliary lemma, which will be used as a building block in the proof.

Lemma C.8. Fix any \( W \). Let \( g \in \mathbb{R}^q \) and \( h \in \mathbb{R}^n \) be random vectors with iid \( N(0,1) \) entries, and let \( W \in \mathbb{R}^{q \times n} \) be a random matrix with iid \( N(0,1) \) entries. Let \( \Sigma \in \mathbb{R}^{q \times q} \) be positive definite. We have that:

\[
\mathbb{E} \min_{\alpha \in \mathbb{R}^n} \| \Sigma^{1/2} W \alpha - x \|_2^2 \leq \mathbb{E} \max_{\beta \geq 0} \max_{\tau > 0} \left[ -\beta \| h \|_2^2 + \| \beta g - \Sigma^{-1/2} x \|_2^2 \left( \Sigma^{-1} + \beta \| h \|_2 \tau I_q \right)^{-1} \right].
\]

Proof. The proof invokes the convex Gaussian min-max lemma (Theorem C.5) via a limiting argument. In what follows, let \( \{ \alpha_k \}_{k \geq 1} \) and \( \{ v_k \}_{k \geq 1} \) be any two positive, increasing sequences of scalars tending to \( +\infty \). It is clear that for every \( W \),

\[
\lim_{k \to \infty} \min_{\| \alpha \|_2 \leq \alpha_k} \| \Sigma^{1/2} W \alpha - x \|_2^2 = \min_{\alpha \in \mathbb{R}^n} \| \Sigma^{1/2} W \alpha - x \|_2^2.
\]

Since \( \alpha = 0 \) is always a feasible solution to \( \min_{\| \alpha \|_2 \leq \alpha_k} \| \Sigma^{1/2} W \alpha - x \|_2^2 \), we have for every \( k \geq 1 \):

\[
0 \leq \min_{\| \alpha \|_2 \leq \alpha_k} \| \Sigma^{1/2} W \alpha - x \|_2^2 \leq \| x \|_2^2.
\]

Therefore, by the dominated convergence theorem,

\[
\mathbb{E} \min_{\alpha \in \mathbb{R}^n} \| \Sigma^{1/2} W \alpha - x \|_2^2 = \mathbb{E} \lim_{k \to \infty} \min_{\| \alpha \|_2 \leq \alpha_k} \| \Sigma^{1/2} W \alpha - x \|_2^2 = \lim_{k \to \infty} \mathbb{E} \min_{\| \alpha \|_2 \leq \alpha_k} \| \Sigma^{1/2} W \alpha - x \|_2^2. \tag{C.2}
\]

We next state two variational forms which we will use:

\[
\frac{1}{2} \| x \|_2^2 = \max_{v \in \mathbb{R}^q} \left\{ v^T x - \frac{\| v \|_2^2}{2} \right\}, \tag{C.3}
\]

\[
\| x \|_2 = \min_{\tau \geq 0} \left\{ \frac{\| x \|_2^2 \tau}{2} + \frac{1}{2 \tau} \right\}. \tag{C.4}
\]

Using the first variational form (C.3), we have for every \( W \) and \( k_1 \geq 1 \),

\[
\min_{\| \alpha \|_2 \leq \alpha_{k_1}} \frac{1}{2} \| \Sigma^{1/2} W \alpha - x \|_2^2 = \min_{\| \alpha \|_2 \leq \alpha_{k_1}} \max_{v \in \mathbb{R}^q} \left[ v^T (\Sigma^{1/2} W \alpha - x) - \frac{\| v \|_2^2}{2} \right]
\]

\[
= \min_{\| \alpha \|_2 \leq \alpha_{k_1}} \max_{v \in \mathbb{R}^q} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \min_{\| \alpha \|_2 \leq \alpha_{k_1}} \max_{\| v \|_2 \leq \| \Sigma W \|_{op} \alpha_{k_1} + \| \Sigma^{1/2} x \|_2} \max_{\| \alpha \|_2 \leq \alpha_{k_1}} \max_{\| v \|_2 \leq \| \Sigma W \|_{op} \alpha_{k_1} + \| \Sigma^{1/2} x \|_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \lim_{k_2 \to \infty} \min_{\| \alpha \|_2 \leq \alpha_{k_1}} \max_{\| v \|_2 \leq \| \Sigma W \|_{op} \alpha_{k_1} + \| \Sigma^{1/2} x \|_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right].
\]
Observe that for every $k_2 \geq 1$,
\[
0 \leq \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\leq \max_{\|v\|_2 \leq v_k_2} \left[ -v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\leq \max_{v \in \mathbb{R}^d} \left[ -v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
= \frac{1}{2} \|x\|^2.
\]

Therefore, by (C.2) and another application of the dominated convergence theorem:
\[
\mathbb{E} \min_{\alpha \in \mathbb{R}^n} \|\Sigma^{1/2} W \alpha - x\|^2 = \lim_{k_1 \to \infty} \mathbb{E} \min_{\|\alpha\|_2 \leq \alpha_k_1} \|\Sigma^{1/2} W \alpha - x\|^2
= \lim_{k_1 \to \infty} \lim_{k_2 \to \infty} \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
= \lim_{k_1 \to \infty} \lim_{k_2 \to \infty} \mathbb{E} \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]. \quad (C.5)
\]

We now apply Theorem C.5 to the expectation on the RHS of (C.5):
\[
\begin{align*}
\mathbb{E} \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} & \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] \\
& = \int_0^\infty \mathbb{P} \left\{ \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ v^T W \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] \geq t \right\} dt \\
& \leq 2 \int_0^\infty \mathbb{P} \left\{ \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] \geq t \right\} dt \\
& = 2 \mathbb{E} \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{\|v\|_2 \leq v_k_2} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] \\
& \leq 2 \mathbb{E} \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{v \in \mathbb{R}^d} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]. \quad (C.6)
\end{align*}
\]

Above, inequality (a) is an application of Theorem C.5. Now for every $k_1$, $g$, and $h$, define
\[
\psi_{k_1}(g, h) := \min_{\|\alpha\|_2 \leq \alpha_k_1} \max_{v \in \mathbb{R}^d} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right].
\]

For every $k_1$, $g$, and $h$, we have
\[
0 \leq \psi_{k_1}(g, h) \leq \max_{v \in \mathbb{R}^d} \left[ -v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] = \frac{1}{2} \|x\|^2.
\]
Furthermore, since \( \{\alpha_k\} \) is an increasing sequence, the sequence \( \{\psi_k(g, h)\}_{k \geq 1} \) is monotonically decreasing. Therefore, by the monotone convergence theorem,

\[
\lim_{k \to \infty} \psi_k(g, h) = \inf \{ \psi_k(g, h) \mid k \in \mathbb{N}_+ \} = \min \max_{\alpha \in \mathbb{R}^n, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right].
\]

Therefore by another application of the dominated convergence theorem, we have that:

\[
\lim_{k \to \infty} \mathbb{E} \min \max_{\|\alpha\|_2 \leq \alpha_k, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] = \mathbb{E} \min \max_{\|\alpha\|_2 \leq \alpha_k, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right] = \mathbb{E} \min \max_{\alpha \in \mathbb{R}^n, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]. \tag{C.7}
\]

Chaining together inequalities (C.5), (C.6), (C.7), we have:

\[
\mathbb{E} \min_{\alpha \in \mathbb{R}^n} \|\Sigma^{1/2} W \alpha - x\|_2^2 \leq 2 \mathbb{E} \min \max_{\alpha \in \mathbb{R}^n, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]. \tag{C.8}
\]

We now proceed to study the RHS of (C.8), which we denote by (AO) (the auxiliary optimization problem):

\[
(AO) := \min \max_{\alpha \in \mathbb{R}^n, v \in \mathbb{R}^q} \left[ \|\alpha\|_2 g^T v + \|v\|_2 h^T \alpha - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \min_{\beta \geq 0} \min_{\theta \in [-1, 1]} \max_{v \in \mathbb{R}^q} \left[ \beta g^T v + \|v\|_2 h^T v - v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \max_{\beta \geq 0 \theta \in [-1, 1]} \left[ \beta g^T v - \beta \|h\|_2 v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \max_{\beta \geq 0 \tau \geq 0 \theta \in [-1, 1]} \left[ \beta g^T v - \beta \|h\|_2 v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \max_{\beta \geq 0 \tau \geq 0} \left[ \beta g^T v - \beta \|h\|_2 v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

\[
= \max_{\beta \geq 0 \tau \geq 0} \left[ \beta g^T v - \beta \|h\|_2 v^T \Sigma^{-1/2} x - \frac{v^T \Sigma^{-1} v}{2} \right]
\]

Above, (b) holds by the variational form (C.4). The proof is now finished after justifying (a). First, let \( h_\beta(\theta, v) \) denote the term in the bracket, so that

\[
(AO) = \min_{\beta \geq 0} \min_{\theta \in [-1, 1]} \max_{v \in \mathbb{R}^q} h_\beta(\theta, v).
\]

Fix a \( \beta \geq 0 \). By weak duality,

\[
\min_{\theta \in [-1, 1]} \max_{v \in \mathbb{R}^q} h_\beta(\theta, v) \geq \max_{v \in \mathbb{R}^q} \min_{\theta \in [-1, 1]} h_\beta(\theta, v) = \max_{v \in \mathbb{R}^q} h_\beta(-1, v).
\]
On the other hand,

\[
\min_{\theta \in [-1,1]} \max_{v \in \mathbb{R}^q} h_\beta(\theta, v) \leq \min_{\theta \in [-1,0]} \max_{v \in \mathbb{R}^q} h_\beta(\theta, v) = \max_{\theta \in \mathbb{R}^q} \min_{\theta \in [-1,0]} h_\beta(\theta, v) = \max_{v \in \mathbb{R}^q} h_\beta(-1, v).
\]

The first equality above is Sion’s minimax theorem, since the function \( \theta \mapsto h_\beta(\theta, v) \) is affine for every \( v \) and the function \( v \mapsto h_\beta(\theta, v) \) is concave for \( \theta \in [-1,0] \). Therefore,

\[
\min_{\theta \in [-1,1]} \max_{v \in \mathbb{R}^q} h_\beta(\theta, v) = \max_{v \in \mathbb{R}^q} h_\beta(-1, v).
\]

\[\square\]

With Lemma C.8 in hand, we can now restate and prove Lemma 6.1.

**Lemma 6.1.** Let \( q, n \) be positive integers with \( q \geq n \) and \( n \geq 2 \). Let \( W \in \mathbb{R}^{q \times n} \) have iid \( N(0,1) \) entries, and let \( \Sigma \in \mathbb{R}^{q \times q} \) be positive definite. Let \( g \sim N(0, I_q) \) and \( h \sim N(0, I_{n-1}) \), with \( g \) and \( h \) independent. Also, let \( \{e_i\}_{i=1}^q \) be the standard basis vectors in \( \mathbb{R}^q \). We have:

\[
\mathbb{E} \operatorname{tr}((W^T \Sigma W)^{-1}) \geq \sum_{i=1}^q \mathbb{E} \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \|h\|_2^2}{\tau} + \|g - e_i\|_2^2 \right] .
\] (6.3)

**Proof.** We rewrite \( \mathbb{E} \operatorname{tr}((W^T \Sigma W)^{-1}) \) in a way that is amenable to Lemma C.8. Let \( w_1 \in \mathbb{R}^q \) denote the first column of \( W \), so that \( W = [w_1 \ W_2] \) with \( W_2 \in \mathbb{R}^{q \times (n-1)} \). We write:

\[
W^T \Sigma W = \begin{bmatrix} \|w_1\|_2^2 & w_1^T \Sigma W_2 \\ W_2^T \Sigma w_1 & W_2^T \Sigma W_2 \end{bmatrix}.
\]

We can use the formula for block matrix inversion to compute the \((1,1)\) entry of \((W^T \Sigma W)^{-1}\). Specifically:

\[
((W^T \Sigma W)^{-1})_{11} = (w_1^T (\Sigma - \Sigma W_2^T (W_2^T \Sigma W_2)^{-1} W_2^T \Sigma) w_1)^{-1}
= (w_1^T \Sigma^{1/2} (I - P_{\Sigma^{1/2} W_2}) \Sigma^{1/2} w_1)^{-1}
= (w_1^T (\Sigma^{1/2} P_{\Sigma^{1/2} W_2}^{\perp} \Sigma^{1/2}) w_1)^{-1}.
\]

Since the columns of \( W \) are all independent and identically distributed, this calculation shows that the law of \((W^T \Sigma W)^{-1})_{ii}\) is the same as the law of \((W^T \Sigma W)^{-1})_{11}\) for all \( i = 1, ..., n \). Therefore:

\[
\mathbb{E} \operatorname{tr}((W^T \Sigma W)^{-1}) = \sum_{i=1}^n \mathbb{E}((W^T \Sigma W)^{-1})_{ii} = n \cdot \mathbb{E}(w_1^T (\Sigma^{1/2} P_{\Sigma^{1/2} W_2}^{\perp} \Sigma^{1/2}) w_1)^{-1}.
\]

By Jensen’s inequality, and using the fact that \( w_1 \) and \( W_2 \) are independent:

\[
\mathbb{E}(w_1^T (\Sigma^{1/2} P_{\Sigma^{1/2} W_2}^{\perp} \Sigma^{1/2}) w_1)^{-1} \geq \left[ \mathbb{E} \operatorname{tr}(\Sigma^{1/2} P_{\Sigma^{1/2} W_2}^{\perp} \Sigma^{1/2}) \right]^{-1}.
\]

This shows that:

\[
\mathbb{E} \operatorname{tr}((W^T \Sigma W)^{-1}) \geq \frac{n}{\mathbb{E} \operatorname{tr}(\Sigma^{1/2} P_{\Sigma^{1/2} W_2}^{\perp} \Sigma^{1/2})}.
\]

75
We next write:

\[ \text{tr}(\Sigma^{1/2}P_{\Sigma^{1/2}W_2}^\perp \Sigma^{1/2}) = \sum_{i=1}^q e_i^T \Sigma^{1/2}P_{\Sigma^{1/2}W_2}^\perp \Sigma^{1/2}e_i = \sum_{i=1}^q \|P_{\Sigma^{1/2}W_2}^\perp \Sigma^{1/2}e_i\|_2^2. \]

Now observe that for any vector \( x \in \mathbb{R}^q \),

\[ \|P_{\Sigma^{1/2}W_2}^\perp x\|_2^2 = \min_{\alpha \in \mathbb{R}^{n-1}} \|\Sigma^{1/2}W_2\alpha - x\|_2^2. \]

Therefore,

\[ \mathbb{E}\text{tr}(\Sigma^{1/2}P_{\Sigma^{1/2}W_2}^\perp \Sigma^{1/2}) = \sum_{i=1}^q \mathbb{E}\min_{\alpha_i \in \mathbb{R}^{n-1}} \|\Sigma^{1/2}W_2\alpha_i - \Sigma^{1/2}e_i\|_2^2. \]

Now invoking Lemma C.8 with \( x = \Sigma^{1/2}e_i \),

\[ \mathbb{E}\text{tr}(\Sigma^{1/2}P_{\Sigma^{1/2}W_2}^\perp \Sigma^{1/2}) \leq \sum_{i=1}^q \mathbb{E}\min_{\beta \geq 0, \tau \geq 0} \max_{\tau I_q} \left[ -\frac{\beta\|h\|_2^2}{\tau^2} + \|\beta g - e_i\|_2^2 (\Sigma^{-1} + \beta\|h\|_2^2 I_q)^{-1} \right], \]

where \( g \sim N(0, I_q) \) and \( h \sim N(0, I_{n-1}) \). The claim now follows by chaining these inequalities together.

We conclude this section with the following technical result which we will use in the sequel.

**Lemma C.9.** Let \( q, n \in \mathbb{N}_+ \) with \( q \geq n \) and \( n \geq 6 \), and let \( \Sigma \in \text{Sym}_q^{\geq 0} \). Let \( g \sim N(0, I_q) \) and \( h \sim N(0, I_{n-1}) \) with \( g \) and \( h \) independent. Define the random variables \( Z_i \) for \( i \in \{1, \ldots, q\} \) as:

\[ Z_i := \min_{\beta \geq 0, \tau \geq 0} \max_{\tau I_q} \left[ -\frac{\beta\|h\|_2^2}{2\tau^2} + \beta^2\|g\|_2^2 (\Sigma^{-1} + \beta\|h\|_2^2 I_q)^{-1} + (\Sigma^{-1} + \beta\|h\|_2^2 I_q)^{-1} \right], \]  

(C.9)

Let \( \{\lambda_i\}_{i=1}^q \) denote the eigenvalues of \( \Sigma^{-1} \) listed in decreasing order. Define \( n_1 \) and the random function \( p(y) \) as:

\[ n_1 := \frac{n}{64}, \quad p(y) := \sum_{i=1}^q \frac{y}{\lambda_i + g_i^2} - \frac{n_1}{2}. \]  

(C.10)

There exists an event \( \mathcal{E} \) (over the probability of \( g \) and \( h \)) such that the following statements hold:

(i) \( \mathbb{P}(\mathcal{E}^c) \leq e^{-n/128} + e^{-q/16} \).

(ii) On \( \mathcal{E} \), there exists a unique root \( y^* \in (0, \infty) \) such that \( p(y^*) = 0 \).

(iii) The following bounds hold for \( i \in \{1, \ldots, q\} \):

\[ Z_i \leq \Sigma_{ii}, \quad 1\{\mathcal{E}\} Z_i \leq 1\{\mathcal{E}\}(\Sigma^{-1} + y^* I_q)^{-1}. \]  

(C.11)
Proof. First, we observe that we can trivially upper bound the value of \( Z_i \) by setting \( \beta = 0 \) and obtaining the bound \( Z_i \leq \Sigma_{ii} \). Furthermore, by the rotational invariance of \( g \) and the fact that \( g \) and \( h \) are independent, we have that \( Z_i \) is equal in distribution to:

\[
Z_i = \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \|h\|_2}{2\tau} + \beta^2 \sum_{i=1}^q \frac{g_i^2}{\lambda_i + \beta \|h\|_2\tau} + (\Sigma^{-1} + \beta \|h\|_2\tau I_q)_{ii}^{-1} \right].
\]

Now, we define the following events:

\[
\mathcal{E}_h := \{ \|h\|_2 \geq \sqrt{n}/8 \}, \quad \mathcal{E}_g := \left\{ \sum_{i=1}^q g_i^2 \geq q/2 \right\},
\]

and put \( \mathcal{E} := \mathcal{E}_h \cap \mathcal{E}_g \). Since \( n \geq 6 \), by a standard computation we have that \( \mathbb{E}\|h\|_2 \geq \sqrt{n - 5} \geq \sqrt{n}/4 \). Therefore, by Gaussian concentration of Lipschitz functions (cf. Wainwright, 2019, Chapter 2), \( \mathbb{P}(\mathcal{E}_h^c) \leq e^{-n/128} \). Furthermore, Lemma C.4 yields that \( \mathbb{P}(\mathcal{E}_g^c) \leq e^{-q/16} \). By a union bound, \( \mathbb{P}(\mathcal{E}^c) \leq e^{-n/128} + e^{-q/16} \).

Now, we bound:

\[
1\{\mathcal{E}\} Z_i \leq 1\{\mathcal{E}\} \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \sqrt{n}}{16\tau} + \frac{\beta^2}{16} \sum_{i=1}^q \frac{g_i^2}{\lambda_i + \beta \sqrt{n}\tau/8} + (\Sigma^{-1} + \beta \sqrt{n\tau/8} I_q)_{ii}^{-1} \right] = \ell(\beta, \tau).
\]

Let us bracket the value of the game \( \min_{\beta \geq 0} \max_{\tau \geq 0} \ell(\beta, \tau) \). We previously noted that \( \ell_i(0, \tau) = \Sigma_{ii} \) for all \( \tau \in [0, \infty) \). Next, for any \( \beta > 0 \), \( \lim_{\tau \to \infty} \ell(\beta, \tau) = 0 \). Hence,

\[
\min_{\beta \geq 0} \max_{\tau \geq 0} \ell(\beta, \tau) \in [0, \Sigma_{ii}].
\]

Recalling from (C.10) that \( n_1 = n/64 \) (so that \( \sqrt{n_1} = \sqrt{n}/8 \)) and defining \( f, q_i \) as:

\[
f(x) := -\frac{x\sqrt{n_1}}{2} + x^2 \sum_{i=1}^q \frac{g_i^2}{\lambda_i + x\sqrt{n_1}},
\]

\[
q_i(x) := (\Sigma^{-1} + x\sqrt{n_1})_{ii}^{-1},
\]

we have that \( \ell(\beta, \tau) = \frac{1}{\tau^2} f(\beta \tau) + q_i(\beta \tau) \).

In order to sharpen our estimate for the value of the game, we will study the positive critical points \( (\beta, \tau) \in \mathbb{R}_{>0}^2 \) of the game \( \min_{\beta} \max_{\tau} \ell(\beta, \tau) \), i.e., the points \( (\beta, \tau) \in \mathbb{R}_{>0}^2 \) satisfying \( \frac{\partial \ell}{\partial \beta}(\beta, \tau) = 0 \) and \( \frac{\partial \ell}{\partial \tau}(\beta, \tau) = 0 \). For \( \tau \neq 0 \), this yields:

\[
0 = \tau^{-2} f'(\beta \tau) \beta - 2\tau^{-3} f(\beta \tau) + q_i'(\beta \tau) \beta,
\]

\[
0 = \tau^{-2} f'(\beta \tau) \tau + q_i'(\beta \tau) \tau.
\]

The second condition yields that \( \tau^{-2} f'(\beta \tau) = -q_i'(\beta \tau) \). Plugging the second condition into the first implies that:

\[
2\tau^{-3} f(\beta \tau) = 0 \iff f(\beta \tau) = 0.
\]
The second condition also implies that the value of the game at such a critical point is $q_i(\beta \tau)$.

Thus, we are interested in the positive roots of $f(x) = 0$. To proceed, recall the definition of $p(y)$ from (C.10):

$$p(y) = \sum_{i=1}^{q} \frac{y}{\lambda_i + y} g_i^2 - \frac{n_1}{2}.$$  

Note that $y^*$ is a positive root of $p$ iff $y^*/\sqrt{n_1}$ is a positive root of $f$. Since $q \geq n$ by assumption, observe that on $E$:

$$\lim_{y \to \infty} p(y) = \sum_{i=1}^{q} g_i^2 > n_1/2 \geq q/2 - n/64 > 0.$$  

On the other hand, $p(0) = -n_1/2 < 0$. Since $p(y)$ is continuous and strictly increasing, on $E$ there exists a unique $y^* \in (0, \infty)$ such that $p(y^*) = 0$. Thus,

$$1\{E\} Z_i \leq 1\{E\}(\Sigma^{-1} + y^* I_q)^{-1}.$$

\[\square\]

### C.5 Proof of Theorem 5.2

**Theorem 5.2** (Need for growth assumptions in Ind-Seq-LS when $m \lesssim n$). There exists universal constant $c_0$, $c_1$, and $c_2$ such that the following holds. Suppose that $P_x = \otimes_{t \geq 1} N(0, 2^t \cdot I_n)$, $n \geq 6$, $mT \geq n$, and $m \leq c_0 n$. Then:

$$R(m, T; T; \{P_x\}) \geq c_1 \sigma^2_p \cdot \frac{p \cdot 2 c_1 n/m}{T}.$$  

**Proof.** Let $\Gamma_T := \Gamma_T(P_x)$. We have that $\Gamma_T = \frac{2}{T}(2^T - 1) I_n \succ 2^T I_n$. By Lemma 5.1:

$$R(m, T; T; \{P_x\}) \geq \sigma^2_p \cdot \mathbb{E} \text{tr}(\Gamma_T^{1/2}(X_{m,T}^T X_{m,T})^{-1} \Gamma_T^{1/2}) \geq \frac{\sigma^2_p}{T} \cdot \mathbb{E} \text{tr}((2^{-T/2} X_{m,T}^T X_{m,T} 2^{-T/2})^{-1}).$$

Since each column of $X_{m,T}$ is independent, the matrix $X_{m,T} 2^{-T/2}$ has the same distribution as $\text{BDiag}(\Theta^{1/2}, m)W$, where $\Theta \in \mathbb{R}^{T \times T}$ is diagonal, $\Theta_{ii} = 2^{i-t}$ for $i \in \{1, \ldots, T\}$, and $W \in \mathbb{R}^{mT \times n}$ has iid $N(0, 1)$ entries. Let $\lambda_t = 2^{T-t}$ for $t \in \{1, \ldots, T\}$. With this notation:

$$\mathbb{E} \text{tr}((2^{-T/2} X_{m,T}^T X_{m,T} 2^{-T/2})^{-1}) = \mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta, m)W)^{-1}).$$

Let $\{g_j\}_{j=1}^m$ be independent isotropic Gaussian random vectors in $\mathbb{R}^T$, and let $h \sim N(0, I_{n-1})$ be independent from $\{g_j\}$. Define the random variables $\{Z_i\}_{i=1}^T$ as:

$$Z_i := \min_{\beta \geq 0, \tau \geq 0} \left[ -\frac{\beta \|h\|_2}{\beta \tau} + \beta^2 \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{g_{j,t}^2}{\lambda_t + \beta \|h\|_2 \tau} + \frac{1}{\lambda_t + \beta \|h\|_2 \tau} \right].$$  

(C.12)
By Lemma 6.1,
\[ \mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta, m) W)^{-1}) \geq \frac{n}{2m} \left( \sum_{i=1}^{T} \mathbb{E}[Z_i] \right)^{-1}. \]

Next, define
\[ n_1 := \frac{n}{64}, \quad p(y) := \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{y g^2_{j,t}}{\lambda_t + y} - \frac{n_1}{2}. \]

Since \( n \geq 6 \) and \( mT \geq n \), we can invoke Lemma C.9 to conclude there exists an event \( \mathcal{E}_1 \) (over the probability of \( \{g_j\} \) and \( h \)) such that:

(a) on \( \mathcal{E}_1 \), there exists a unique root \( y^* \in (0, \infty) \) such that \( p(y^*) = 0 \),

(b) the following inequalities holds:
\[ Z_i \leq \frac{1}{\lambda_i}, \quad 1\{\mathcal{E}_1\}Z_i \leq 1\{\mathcal{E}_1\} \frac{1}{\lambda_i + y^*}, \]
(c) the following estimate holds:
\[ \mathbb{P}(\mathcal{E}_1^{c}) \leq e^{-n/128} + e^{-mT/16}. \]

Now, let \( c = 1/20 \), and assume that \( cn_1/m \geq 4 \). We can check easily that \( \lceil cn_1/m \rceil \leq T \). Fix a \( \delta \in (0, e^{-2}] \) to be chosen later. Define the integer \( T_c := \lceil cn_1/m \rceil \in \{4, ..., T\} \), and the events (over the probability of \( \{g_j\} \) and \( h \)):
\[ \mathcal{E}^{g,T_c}_2 := \left\{ \sum_{j=1}^{m} \sum_{t=1}^{T_c} g^2_{j,t} \leq 5mT_c \right\}, \quad \mathcal{E}^{g,+}_2 := \left\{ \max_{t=1,...,T} \sum_{j=1}^{m} g^2_{j,t} \leq 2m + 4 \log \left( \frac{t^2 \pi^2}{6\delta} \right) \right\}. \]

By Lemma C.4, \( \mathbb{P}((\mathcal{E}^{g,T_c}_2)^c) \leq e^{-mT_c} \). Next, Gaussian concentration for Lipschitz functions (cf Wainwright, 2019, Chapter 2) yields, for any \( \eta \in (0, 1) \):
\[ \max_{t=1,...,T} \mathbb{P} \left\{ \sqrt{\sum_{j=1}^{m} g^2_{j,t}} \geq \sqrt{m + 2 \log(1/\eta)} \right\} \leq \eta. \]

Hence by a union bound, and the fact that \( 6\delta/\pi^2 \sum_{t=1}^{T} t^{-2} \leq 6\delta/\pi^2 \sum_{t=1}^{\infty} t^{-2} = \delta \), we have that \( \mathbb{P}((\mathcal{E}^{g,+}_2)^c) \leq \delta \). Putting \( \mathcal{E} := \mathcal{E}_1 \cup \mathcal{E}^{g,T_c}_2 \cup \mathcal{E}^{g,+}_2 \), we have:
\[ \mathbb{P}(\mathcal{E}^{c}) \leq e^{-n/128} + e^{-mT/16} + e^{-mT_c} + \delta \leq e^{-n/128} + e^{-mT/16} + e^{-cn_1} + \delta. \]
Next, noting that \( t/2 \geq \log_2 \log((t+1)^2 \pi^2/(6\delta)) \) for all \( t \geq 4 \):

\[
\sum_{t=T_c}^{T-1} 2^{-t} \log((t+1)^2 \pi^2/(6\delta)) = \sum_{t=T_c}^{T-1} 2^{-t+t+\log_2 \log((t+1)^2 \pi^2/(6\delta))} + \log(1/\delta) \sum_{t=T_c}^{T-1} 2^{-t} \\
\leq \sum_{t=T_c}^{T-1} 2^{-t/2} + \log(1/\delta) \sum_{t=T_c}^{T-1} 2^{-t} \\
= \sqrt{2}/(\sqrt{2} - 1)(2^{-T_c/2} - 2^{-T/2}) + 2 \log(1/\delta)(2^{-T_c} - 2^{-T}) \\
\leq (4 + 2 \log(1/\delta))2^{-T_c/2} \leq 4 \log(1/\delta)2^{-T_c/2} \quad \text{since } \delta \in (0, e^{-2}) \quad \text{(C.15)}
\]

Now, on \( E \):

\[
\frac{n_1}{2} = \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{y^* g_{j,t}^2}{\lambda_t + y^* g_{j,t}} \quad \text{since } p(y^*) = 0 \\
\leq \sum_{j=1}^{m} \sum_{t=1}^{T_c} g_{j,t}^2 + y^* \sum_{j=1}^{m} \sum_{t=T_c}^{T-1} 2^{-t} g_{j,t+1}^2 \\
= \sum_{j=1}^{m} \sum_{t=1}^{T_c} g_{j,t}^2 + y^* \sum_{j=1}^{m} \sum_{t=T_c}^{T-1} 2^{-t} g_{j,t+1}^2 \\
\leq 5mT_c + y^* \sum_{t=T_c}^{T-1} 2^{-t} \left[ 2m + 4 \log((t+1)^2 \pi^2/(6\delta)) \right] \quad \text{using } E \\
\leq 5mT_c + 4my^*2^{-T_c} + 16y^* \log(1/\delta)2^{-T_c/2} \quad \text{using (C.15)} \\
\leq 5mT_c + 18my^* \log(1/\delta)2^{-T_c/2} \quad \text{since } \delta \in (0, e^{-2}).
\]

This inequality implies the following lower bound on \( y^* \):

\[
y^* \geq \frac{2^{cn_1/(2m)}}{18 \log(1/\delta)} \left[ \frac{n_1}{2m} - 5c \frac{n_1}{m} - 5 \right] \\
= \frac{2^{cn_1/(2m)}}{18 \log(1/\delta)} \left[ \frac{n_1}{4m} - 5 \right] \quad \text{since } c = 1/20 \\
\geq \frac{2^{cn_1/(2m)}}{144 \log(1/\delta)} \frac{n_1}{m} \quad \text{since } cn_1/m \geq 4 \implies n_1/(8m) \geq 5 \\
=: y^*.
\]
We now bound,

\[
\sum_{i=1}^{T} \mathbb{E}[Z_i] = \sum_{i=1}^{T} \left[ \mathbb{E}[\{E\} Z_i] + \mathbb{E}[\{E\}^c] Z_i] \right] \\
\leq \sum_{i=1}^{T} \left( \mathbb{E} \left[ \{E\} \frac{1}{\lambda_i + y^*} \right] + \mathbb{P}(\{E\}^c) \frac{1}{\lambda_i} \right) \quad \text{using (C.13)} \\
\leq \sum_{i=1}^{T} \frac{1}{\lambda_i + y^*} + \mathbb{P}(\{E\}^c) \sum_{i=1}^{T} \frac{1}{\lambda_i} \\
\leq \sum_{t=0}^{T-1} \frac{1}{2^t + y^*} + 2 \left( e^{-n/128} + e^{-mT/16} + e^{-cn_1} + \delta \right) \quad \text{using (C.14)} \\
\leq \frac{T_c}{y^*} + 2 \cdot 2^{-T_c} + 2 \left( e^{-n/128} + e^{-mT/16} + e^{-cn_1} + \delta \right) \\
\leq 288c \log(1/\delta) 2^{-cn_1/(2m)} + 2 \cdot 2^{-cn_1/m} \\
+ 2 \left( e^{-n/128} + e^{-mT/16} + e^{-cn_1} + \delta \right).
\]

Since \( cn_1/m \geq 4 \), we can choose \( \delta = e^{-cn_1/(2m)} \in (0, e^{-2}] \) and obtain:

\[
\sum_{i=1}^{T} \mathbb{E}[Z_i] \leq 144c \frac{2^{n_1}}{m} 2^{-cn_1/(2m)} + 2 \cdot 2^{-cn_1/m} + 2 \left( e^{-n/128} + e^{-mT/16} + e^{-cn_1} + e^{-cn_1/(2m)} \right).
\]

Since \( 1 \leq cn_1/(4m) \), \( mT \geq n \), and \( m \geq 1 \), this inequality implies there exists universal positive constants \( c_1, c_2 \) such that:

\[
\sum_{i=1}^{T} \mathbb{E}[Z_i] \leq \frac{c_1 n}{m} 2^{-c_2 n/m}.
\]

Hence:

\[
R(m, T, T; \{P_x\}) \geq \frac{\sigma_{\xi}^2 \rho}{T} \frac{n}{2m} \left[ \sum_{i=1}^{T} \mathbb{E}[Z_i] \right]^{-1} \geq \frac{\sigma_{\xi}^2 \rho}{T} \frac{n}{2m} \frac{m}{c_1 n} 2^{c_2 n/m} = \frac{\sigma_{\xi}^2 \rho 2^{c_2 n/m}}{2c_1 T}.
\]

\[\square\]

### C.6 Block decoupling

We now use a block decoupling argument to study lower bounds on the risk. The first step is the following result, which bounds the risk from below by a particular random gramian matrix.

**Lemma C.10.** Let \( n = dr \) with both \( d, r \) positive integers. Define \( \mathcal{I}_r := \{1, 1 + r, ..., 1 + (T - 1)r\} \), and let \( E_{\mathcal{I}_r} \in \mathbb{R}^{T \times Tr} \) denote the linear operator which extracts the coordinates in \( \mathcal{I}_r \), so that \( (E_{\mathcal{I}_r} x)_i = x_{1+(i-1)r} \) for \( i = 1, ..., T \). Recall the following definitions from Equation (6.9):

\[
\Psi_{r,T,T'} = \text{BDiag}(\Gamma_{T'}^{-1/2}(J_r), T) \text{BDiag}(J_r, T) \in \mathbb{R}^{Tr \times Tr},
\]

\[
\Theta_{r,T,T'} = E_{\mathcal{I}_r} \Psi_{r,T,T} \Psi_{r,T,T'}^T \Psi_{r,T,T'} E_{\mathcal{I}_r}^T \in \mathbb{R}^{Tr \times T}.
\]

81
Then, for \( A = \text{BDiag}(J_r, d) \) we have:

\[
\mathbb{E}_{\otimes_{i=1}^{m}\mathbb{P}_i}\left[ \text{tr}\left( \Gamma_{T'}^{-1/2}(A)(X_{m,T}X_{m,T})^{-1}\Gamma_{T'}^{-1/2}(A)\right) \right] \geq \mathbb{E}\text{tr}(W^{T}\text{BDiag}(\Theta_{r,T,T'}, m)W)^{-1},
\]

where \( W \in \mathbb{R}^{mT \times d} \) is a matrix with independent \( N(0, 1) \) entries.

**Proof.** We apply Proposition C.3 with:

\[
M = X_{m,T}\Gamma_{T'}^{-1/2}, \quad I = \{1, 1 + r, 1 + 2r, ..., 1 + (d - 1)r\}, \quad |I| = d.
\]

Note that the block diagonal structure of \( A \) yields the same block diagonal structure on \( \Gamma_{T'} \) and its inverse square root, specifically \( \Gamma_{T'}(A) = \text{BDiag}(\Gamma_{T'}(J_r), d) \) and \( \Gamma_{T'}^{-1/2}(A) = \text{BDiag}(\Gamma_{T'}^{-1/2}(J_r), d) \).

Hence, it is not hard to see that the columns of \( ME_{I}^{T} \) are not only independent, but also identically distributed. Furthermore, the distribution of each column obeys a multivariate Gaussian in \( \mathbb{R}^{mT} \).

Hence, \( ME_{I}^{T} \) is equal in distribution to \( Q_{m,T}^{1/2}W \), where \( W \in \mathbb{R}^{mT \times d} \) is a matrix of iid Gaussians and \( Q_{m,T} \in \text{Sym}_{mT}^{>0} \) is a positive definite covariance matrix to be determined. Furthermore, because \( ME_{I}^{T} \) contains the vertical concatenation of \( m \) independent trajectories, \( Q_{m,T} \) itself is block diagonal:

\[
Q_{m,T} = \text{BDiag}(Q_T, m), \quad Q_T \in \text{Sym}_{T}^{>0}.
\]

Let us now compute an expression for \( Q_T \). Consider the dynamics:

\[
x_{t+1}^{r} = J_rx_{t}^{r} + w_{t}^{r}, \quad x_{0}^{r} = 0, \quad w_{t}^{r} \sim N(0, \sigma_{w}^{2}I_r).
\]

It is not hard to see that, with \( w_{0:T-1}^{r} = (w_{0}, ..., w_{T-1}) \in \mathbb{R}^{rT} \),

\[
\begin{bmatrix}
\Gamma_{T'}^{-1/2}(J_r)x_{1}^{r} \\
\vdots \\
\Gamma_{T'}^{-1/2}(J_r)x_{T}^{r}
\end{bmatrix} = \Psi_{r,T,T'}w_{0:T-1}^{r}.
\]

From this, we see that every column of \( ME_{I}^{T} \) is equal in distribution to \( E_{I,r}\Psi_{r,T,T'}w_{0:T-1}^{r} \), and therefore has distribution \( N(0, E_{I,r}\Psi_{r,T,T'}\Psi_{r,T,T'}^{T}E_{I,r}^{T}) \). Therefore:

\[
Q_T = E_{I,r}\Psi_{r,T,T'}\Psi_{r,T,T'}^{T}E_{I,r}^{T} = \Theta_{r,T,T'}.
\]

The claim now follows. \( \square \)

### C.7 Eigenvalue analysis of a tridiagonal matrix

For any \( T \in \mathbb{N}_{+} \), recall that \( L_T \) denotes the \( T \times T \) lower triangle matrix with ones in the lower triangle, and \( \text{Tr}(a, b; T) \) denotes the symmetric \( T \times T \) tri-diagonal matrix with \( a \) on the diagonal and \( b \) on the lower and upper off-diagonals. In this section, we study the eigenvalues of \( (L_TL_T^{T})^{-1} \), which we denote by \( S_T \):

\[
S_T = (L_TL_T^{T})^{-1} = \text{Tr}(2, -1; T) - e_Te_T^{T}.
\]

(C.16)

Understanding the eigenvalues of this matrix will be necessary in the proof of Lemma C.14. The following result sharply characterizes the spectrum of \( S_T \) up to constant factors.
Lemma C.11. Suppose $T \geq 8$. For all $k = 1, \ldots, T$, we have that:

$$0.02 \frac{k^2}{T^2} \leq \lambda_{T-k+1}(S_T) \leq \pi^2 \frac{k^2}{T^2}.$$

**Proof.** We prove the upper bound in Proposition C.12, and the lower bound in Proposition C.13. \qed

The next result gives the necessary upper bounds on the eigenvalues of $S_T$.

**Proposition C.12.** We have that:

$$\lambda_{T-k+1}(S_T) \leq \pi^2 \frac{k^2}{T^2}, \quad k = 1, \ldots, T.$$

**Proof.** By (C.16), we immediately produce a semidefinite upper bound on $S_T$:

$$S_T = \text{Tri}(2, -1; T) - e_T e_T^T \preceq \text{Tri}(2, -1; T).$$

Therefore by the Courant min-max theorem, followed by the closed-form expression for the eigenvalues of $\text{Tri}(2, -1; T)$, we have:

$$\lambda_{T-k+1}(S_T) \leq \lambda_{T-k+1}(\text{Tri}(2, -1; T)) = 2 \left( 1 - \cos \left( \frac{k \pi}{T + 1} \right) \right), \quad k = 1, \ldots, T.$$

Next, we have the following elementary lower bounds for $\cos(x)$ on $x \in [0, \pi]$:

$$\cos(x) \geq \begin{cases} 1 - x^2/2 & \text{if } x \in [0, 2\pi/3], \\ (x - \pi)^2/4 - 1 & \text{if } x \in [2\pi/3, \pi]. \end{cases}$$

Therefore, when $k \in \left\{ 1, \ldots, \left\lfloor \frac{2(T+1)}{3} \right\rfloor \right\}$, we immediately have that:

$$\lambda_{T-k+1}(S_T) \leq \pi^2 \frac{k^2}{(T+1)^2}.$$

The case when $k \in \left\{ \left\lfloor \frac{2(T+1)}{3} \right\rfloor + 1, \ldots, T \right\}$ is more involved. Plugging in the cosine lower bound, for $k \in \left\{ \left\lfloor \frac{2(T+1)}{3} \right\rfloor + 1, \ldots, T \right\}$,

$$\lambda_{T-k+1}(S_T) \leq 4 - \pi^2 \left( 1 - \frac{k}{T + 1} \right)^2$$

$$\leq 4 \left[ 1 - \left( 1 - \frac{k}{T + 1} \right)^2 \right]$$

$$= 4 \left( \frac{k}{T + 1} \right) \left( 2 - \frac{k}{T + 1} \right)$$

$$= 4 \left( \frac{k}{T + 1} \right) \left( \frac{2(T+1) - k}{T + 1} \right)$$

$$\leq 4 \left( \frac{k}{T + 1} \right) \left( \frac{3k - k}{T + 1} \right)$$

$$= 4 \frac{k^2}{(T+1)^2}$$

since $k \geq 2(T + 1)/3$

$$= \frac{8k^2}{(T+1)^2}.$$

The claim now follows by taking the maximum over the upper bounds. \qed

---

83
We now move to the lower bound on \( \lambda_{T-k+1}(S_T) \). At this point, it would be tempting to use Weyl’s inequalities, which imply that \( \lambda_i(S_T) \geq \lambda_i(\text{Tri}(2, -1; T)) - 1 \). However, this bound becomes vacuous, since \( \lambda_T(\text{Tri}(2, -1; T)) \lesssim 1/T^2 \). To get finer grained control, we need to use the eigenvalue interlacing result of Kulkarni et al. (1999). This is done in the following result:

**Proposition C.13.** Suppose that \( T \geq 8 \). We have that

\[
\lambda_{T-k+1}(S_T) \geq 0.02 \frac{k^2}{T^2}, \quad k = 1, \ldots, T.
\]

**Proof.** The proof relies on the interlacing result from Kulkarni et al. (1999, Theorem 4.1). However, the interlacing result does not cover the minimum eigenvalue of \( S_T \), so we first explicitly derive a lower bound for \( \lambda_{\min}(S_T) \). To do this, we note that:

\[
\lambda_{\min}(S_T) = \lambda_{\min}((L_T L_T^T)^{-1}) = \frac{1}{\|L_T\|_{\text{op}}^2}.
\]

Letting \( l_i \in \mathbb{R}^T \) denote the \( i \)-th column of \( L_T \), by the variational form of the operator norm followed by Cauchy-Schwarz,

\[
\|L_T\|_{\text{op}} = \max_{\|v\|_2 = 1} \|L_T v\|_2 \leq \max_{\|v\|_2 = 1} \sum_{i=1}^T \|l_i\|_2 |v_i| \leq \sqrt{\sum_{i=1}^T \|l_i\|_2^2} = \sqrt{T(T+1)/2}.
\]

Hence:

\[
\lambda_{\min}(S_T) \geq \frac{2}{T(T+1)} \geq \frac{1}{T^2}.
\]

Now we may proceed with the remaining eigenvalues. We can write \( S_T \) as the following block matrix, with \( e_{T-1} \in \mathbb{R}^{T-1} \) denoting the \((T-1)\)-th standard basis vector:

\[
S_T = \begin{bmatrix}
\text{Tri}(2, -1; T-1) & -e_{T-1} \\
-e_{T-1}^T & 1
\end{bmatrix}.
\]

This matrix is of the form studied in Kulkarni et al. (1999, Theorem 4.1); for what follows we will borrow their notation. Let \( U_T(x) \) denote the \( T \)-th degree Chebyshev polynomial of the 2nd kind. We know that the eigenvalues of \( S_T \) are given by \( \lambda = 2(1-x) \), where \( x \) are the roots of the polynomial \( p_T(x) \) defined as:

\[
p_T(x) := (1 + 2x)U_{T-1}(x) - U_{T-2}(x). \quad \text{(C.17)}
\]

Therefore, letting \( \psi_1 \leq \ldots \leq \psi_T \) denote the roots of \( \text{(C.17)} \) listed in increasing order, we have:

\[
\lambda_i(S_T) = 2(1 - \psi_i), \quad i = 1, \ldots, T.
\]

Let \( \eta_1 \leq \ldots \leq \eta_{T-2} \) denote the \( T-2 \) roots of \( U_{T-2}(x) \) listed in increasing order. Put \( \eta_0 := -\infty \) and \( \eta_{T-1} := +\infty \). Because the roots of \( U_{T-2}(x) \) are given by \( x = \cos\left(\frac{k\pi}{T-1}\right), \ k = 1, \ldots, T-2 \), we have that:

\[
\eta_i = \cos\left(\frac{(T-1-i)\pi}{T-1}\right), \quad i = 1, \ldots, T-2.
\]

84
Kulkarni et al. (1999, Theorem 4.1) states that there is exactly one root of $p_T(x)$ in each of the intervals $(\eta_j, \eta_{j+1})$ for $j \in \{0, ..., T-2\} \setminus \{i_*\}$, with $i_*$ satisfying:

$$i_* \in \begin{cases} \left\{ \left\lfloor \frac{2(T-1)}{3} \right\rfloor \right\} & \text{if } 2(T-1) \mod 3 \neq 0, \\ \left\{ \frac{2(T-1)}{3}, \frac{2(T-1)}{3} + 1 \right\} & \text{o.w.,} \end{cases}$$

and furthermore $(\eta_*, \eta_{i_*+1})$ contains exactly two roots of $p_T(x)$. Therefore, for $i \in \{i_*+3, ..., T-1\}$:

$$\psi_i \leq \eta_{i-1} \Rightarrow \lambda_i(S_T) \geq 2(1 - \eta_{i-1}) = 2 \left(1 - \cos \left(\frac{(T-i)\pi}{T-1}\right)\right).$$

For $i \in \{i_*+3, ..., T-1\}$, we have:

$$\frac{T-i}{T-1} \leq \frac{T-i_*-3}{T-1} = \frac{T - \left(\frac{2(T-1)}{3} - 1\right) - 3}{T-1} = \frac{1}{3} - \frac{1}{T-1} \leq \frac{1}{3}.$$ 

It is elementary to check that:

$$2 \left(1 - \cos(x)\right) \geq \frac{x^2}{2} \quad \forall x \in [0, \pi/3].$$

Therefore for $i \in \{i_*+3, ..., T-1\}$,

$$\lambda_i(S_T) \geq \frac{\pi^2}{2} \left(\frac{T-i}{T-1}\right)^2.$$ 

Furthermore, for $i \in \{1, ..., i_*+2\}$,

$$\psi_i \leq \eta_{i+1} \Rightarrow \lambda_i(S_T) \geq 2(1 - \eta_{i+1}) = 2 \left(1 - \cos \left(\frac{(T-1-i_*-1)\pi}{T-1}\right)\right) \geq 2(1 - \cos(\pi/21)).$$

The last inequality holds by:

$$\cos \left(\frac{(T-1-i_*-1)\pi}{T-1}\right) \leq \cos \left(\frac{(T-1) - (2(T-1)/3 + 2)\pi}{T-1}\right) \quad \text{since } i_* \leq \frac{2(T-1) - 1}{3} + 1$$

$$= \cos \left(\frac{1}{3} - \frac{2}{T-1}\right) \pi \leq \cos(\pi/21) \quad \text{since } T \geq 8.$$ 

Summarizing, we have shown that:

$$\lambda_{T-k+1}(S_T) \geq \begin{cases} \frac{1}{T^2} & \text{if } k = 1, \\ \frac{\pi^2}{2} \left(\frac{k-1}{T-1}\right)^2 & \text{if } k \in \{2, ..., T-i_*-2\}, \\ 2(1 - \cos(\pi/21)) & \text{if } k \in \{T-i_*-1, ..., T\}. \end{cases}$$

Since $\frac{k-1}{T-1} \geq \frac{k}{T}$ when $k \geq 2$, and since $2(1 - \cos(\pi/21)) \geq 2(1 - \cos(\pi/21)) \frac{k^2}{T^2}$ trivially, we have shown the desired conclusion:

$$\lambda_{T-k+1}(S_T) \geq \min \left\{ 1, \frac{\pi^2}{8}, 2(1 - \cos(\pi/21)) \right\} \frac{k^2}{T^2} \geq 0.02 \frac{k^2}{T^2}, \quad k = 1, ..., T.$$
C.8 A risk lower bound in the few trajectories regime

Lemma C.14. There exist universal positive constants $c_0$, $c_1$, $c_2$, and $c_3$ such that the following is true. Suppose $A \subseteq \mathbb{R}^{n \times n}$ is any set containing $I_n$. Let $T \geq c_0$, $n \geq c_1$, $mT \geq n$, and $m \leq c_2 n$. We have that:

$$R(m, T, T'; \{P^A_x \mid A \in A\}) \geq c_3 \sigma_2^2 p \cdot \frac{n^2}{m^2 T} \cdot \frac{T'}{T}.$$ 

Proof. Let $\{g_j\}_{j=1}^m$ be independent $N(0, I_T)$ random vectors, and let $h \sim N(0, I_{n-1})$ be independent from $\{g_j\}$. Let $\{\lambda_i\}_{i=1}^T$ denote the eigenvalues of $\Theta_{1,T,T}^{-1}$ listed in decreasing order. Define the random variables $\{Z_i\}_{i=1}^T$ as:

$$Z_i := \min_{\beta \geq 0} \max_{\tau \geq 0} \left[ -\frac{\beta \|h\|_2^2}{2\tau} + \beta^2 \sum_{j=1}^m \sum_{t=1}^T \frac{g_{j,t}^2}{\lambda_t + \beta \|h\|_2^2} + (\Theta_{1,T,T}^{-1})_{ii} (\Theta_{1,T,T}^{-1})_{ii} \right]. \quad (C.18)$$

We now lower bound the minimax risk as follows:

$$\begin{align*}
R(m, T, T', \{P^A_x\}) &\geq \sigma_2^2 p \cdot \mathbb{E}_{\otimes_{i=1}^m P^A_x} \left[ \text{tr} \left( \Gamma_T(I_n)^{1/2}(X_{m,T}^T X_{m,T})^{-1} \Gamma_T(I_n)^{1/2} \right) \right] \quad \text{by Lemma 5.1} \\
&\geq \sigma_2^2 p \cdot \mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta_{1,T,T}, m) W)^{-1}) \quad \text{by Lemma C.10} \\
&= \sigma_2^2 p \cdot \frac{T'}{T+1} \cdot \mathbb{E} \text{tr}((W^T \text{BDiag}(\Theta_{1,T,T}, m) W)^{-1}) \quad \text{using (6.10)} \\
&\geq \sigma_2^2 p \cdot \frac{T'}{2T} \cdot \mathbb{E} \text{tr}((W^T \text{Diag}(\Theta_{1,T,T}, m) W)^{-1}) \\
&\geq \sigma_2^2 p \cdot \frac{T'}{2T} \cdot \frac{n}{2m} \cdot \left[ \sum_{i=1}^T \mathbb{E}[Z_i] \right]^{-1} \quad \text{by Lemma 6.1.} \quad (C.19)
\end{align*}$$

Next, define:

$$n_1 := \frac{n}{64}, \quad p(y) := \sum_{j=1}^m \sum_{t=1}^T \frac{y}{\lambda_t + y g_{j,t}^2} - \frac{n_1}{2}.$$ 

Assuming that $c_1 \geq 6$ so that $n \geq 6$ and $mT \geq n$, we can invoke Lemma C.9 to conclude there exists an event $\mathcal{E}_1$ (over the probability of $\{g_j\}$ and $h$) such that:

(a) on $\mathcal{E}_1$, there exists a unique root $y^* \in (0, \infty)$ such that $p(y^*) = 0$,

(b) the following inequalities hold:

$$Z_i \leq (\Theta_{1,T,T})_{ii}, \quad 1\{\mathcal{E}_1\} Z_i \leq 1\{\mathcal{E}_1\} \frac{1}{\lambda_i + y^*}; \quad (C.20)$$

(c) the following estimate holds:

$$\mathbb{P}(\mathcal{E}_1^c) \leq e^{-n/128} + e^{-mT/16}.$$
The remainder of the proof is to estimate a lower bound on $y^*$. Towards this goal, we define an auxiliary function:

$$
\tilde{p}(y) := \mathbb{E}[p_1(y)] = m \sum_{t=1}^{T} \frac{y}{\lambda_t + y} - \frac{n_1}{2}.
$$

Let $\bar{y}^*$ be the unique solution to $\tilde{p}(y) = 0$. A unique root exists because $\tilde{p}(0) < 0$, $\lim_{y \to \infty} \tilde{p}(y) = mT - n_1/2 \geq n - n/64 > 0$, and $\tilde{p}$ is continuous and strictly increasing. We derive a lower bound on $y^*$ through a lower bound on $\bar{y}^*$. For any fixed $\alpha > 0$, the function $x \mapsto x^{\alpha} + x$ is monotonically increasing and concave on $\mathbb{R}_{>0}$. Therefore, the function $p(y)$ is monotonically increasing and concave on $\mathbb{R}_{>0}$. By Proposition C.2, the root of the linear approximation to $p(y)$ at $\bar{y}^*$ is a lower bound to $y^*$:

$$
\mathbb{E} \{ E_1 \} y^* \geq \mathbb{E} \{ E_1 \} \left[ \bar{y}^* - \frac{p(\bar{y}^*)}{p'(\bar{y}^*)} \right]. \quad (C.21)
$$

Equation (C.21) is a crucial step for the proof, because it turns analyzing $y^*$, which is the root of a random function, into analyzing the pointwise evaluation of a random function on a deterministic quantity. To lower bound the RHS, we need a upper bound on $p(\bar{y}^*)$ and lower bounds on both $\bar{y}^*$ and $p'(\bar{y}^*)$.

**Upper and lower bounds on $\bar{y}^*$.** We first derive a crude upper bound by Jensen’s inequality. Observe that $\tilde{p}(\bar{y}^*) = 0$ implies that:

$$
mT - \frac{n_1}{2} = m \sum_{t=1}^{T} \frac{\lambda_t}{\lambda_t + \bar{y}^*}.
$$

The function $x \mapsto x/(x + \bar{y}^*)$ is concave on $\mathbb{R}_{>0}$. Let $\tilde{\lambda} := \frac{1}{T} \sum_{t=1}^{T} \lambda_t$. Jensen’s inequality states that $T \frac{\tilde{\lambda}}{\lambda + \bar{y}^*} \geq \sum_{t=1}^{T} \frac{\lambda_t}{\lambda_t + \bar{y}^*}$. Therefore:

$$
1 - \frac{n_1}{2mT} \leq \frac{\tilde{\lambda}}{\lambda + \bar{y}^*} \Rightarrow \bar{y}^* \leq \frac{n_1}{2mT} \frac{1}{1 - n_1/(2mT)}.
$$

Recalling the definition of $S_T$ from (C.16), we can immediately bound

$$
\tilde{\lambda} = \frac{1}{T} \sum_{t=1}^{T} \lambda_t = \frac{1}{T} \text{tr}(\Theta_{1,T,T}^{-1}) = \frac{1}{T} \text{tr} \left( \frac{T + 1}{2} S_T \right) \leq \text{tr}(S_T) = 2T - 1 \leq 2T.
$$

Therefore, since $mT \geq n$,

$$
\bar{y}^* \leq \frac{n_1}{m} \frac{1}{1 - n_1/(2mT)} \leq \frac{2n_1}{m}.
$$

Now for the lower bound on $\bar{y}^*$. Noting that $\lambda_{T-k+1} = \lambda_{T-k+1}(\Theta_{1,T,T}^{-1}) = \frac{T+1}{T} \lambda_{T-k+1}(S_T)$, Corollary C.11 implies (assuming that $c_0 \geq 8$ so $T \geq 8$) that

$$
0.01 \frac{k^2}{T} \leq \lambda_{T-k+1} \leq \frac{\pi^2 k^2}{T}, \quad k = 1, ..., T. \quad (C.22)
$$
Therefore, $\bar{p}(\bar{y}^*) = 0$ implies that:

$$\frac{1}{\bar{y}^*} = \frac{2m}{n_1} \sum_{t=1}^{T} \frac{1}{\lambda_t + \bar{y}^*} \leq \frac{2m}{n_1} \sum_{t=1}^{T} \frac{1}{0.01t^2/T + \bar{y}^*} \leq \frac{2m}{n_1} \int_0^{T} \frac{1}{0.01x^2/T + \bar{y}^*} dx = 20m\sqrt{T} \frac{\tan^{-1} \left( \frac{\sqrt{T}}{10\sqrt{\bar{y}^*}} \right)}{n_1\sqrt{\bar{y}^*}} \leq \frac{10\pi m\sqrt{T}}{n_1\sqrt{\bar{y}^*}}.$$ 

Solving for $\bar{y}^*$ yields:

$$\bar{y}^* \geq \frac{1}{100\pi^2 \frac{n_1^2}{m^2 T}}.$$ 

Next, we use this lower bound on $\bar{y}^*$ to bootstrap our upper bound $\bar{y}^* \leq 2n_1/m$ into something stronger. Using the upper bounds on $\lambda_t$ from (C.22),

$$\frac{1}{\bar{y}^*} = \frac{2m}{n_1} \sum_{t=1}^{T} \frac{1}{\lambda_t + \bar{y}^*} \geq \frac{2m}{n_1} \sum_{t=1}^{T} \frac{1}{\pi^2 t^2/T + \bar{y}^*} \geq \frac{2m}{n_1} \int_1^{T+1} \frac{1}{\pi^2 x^2/T + \bar{y}^*} dx = \frac{2m\sqrt{T}}{\pi n_1 \sqrt{\bar{y}^*}} \left[ \tan^{-1} \left( \frac{(T+1)\pi}{\sqrt{T} \bar{y}^*} \right) - \tan^{-1} \left( \frac{\pi}{\sqrt{T} \bar{y}^*} \right) \right].$$

The function $\tan^{-1}(x)$ is increasing. Using the $\bar{y}^* \leq 2n_1/m$ upper bound and the assumption that $mT \geq n$,

$$\frac{(T+1)\pi}{\sqrt{T} \bar{y}^*} \geq \pi \sqrt{\frac{mT}{2n_1}} \geq \pi \sqrt{32} \implies \tan^{-1} \left( \frac{(T+1)\pi}{\sqrt{T} \bar{y}^*} \right) \geq \tan^{-1} (\pi \sqrt{32}).$$

On the other hand, using the bound $\bar{y}^* \geq \frac{1}{100\pi^2 \frac{n_1^2}{m^2 T}}$ and the assumption that $m \leq \frac{\sqrt{2}n}{320}$,

$$\frac{\pi}{\sqrt{T} \bar{y}^*} \leq 10\pi \frac{m}{n_1} \leq \pi \sqrt{32}/2 \implies \tan^{-1} \left( \frac{\pi}{\sqrt{T} \bar{y}^*} \right) \leq \tan^{-1} (\pi \sqrt{32}/2).$$

Combining these inequalities:

$$\frac{1}{\bar{y}^*} \geq \frac{2m\sqrt{T}}{\pi n_1 \sqrt{\bar{y}^*}} \left[ \tan^{-1} (\pi \sqrt{32}) - \tan^{-1} (\pi \sqrt{32}/2) \right] \geq \frac{2 \cdot 0.05 \cdot m\sqrt{T}}{\pi} \frac{1}{n_1 \sqrt{\bar{y}^*}} \implies \bar{y}^* \leq 791\pi^2 \frac{n_1^2}{m^2 T}.$$ 

Therefore we have the following upper and lower bounds on $\bar{y}^*$:

$$\frac{1}{100\pi^2 \frac{n_1^2}{m^2 T}} \leq \bar{y}^* \leq \min \left\{ 791\pi^2 \frac{n_1^2}{m^2 T}, 2 \frac{n_1}{m} \right\}. \quad (C.23)$$

For the remainder of the proof, in order to avoid precisely tracking constants, we let $c_0, c_1, c_2, c_3$ be any positive universal constants such that:

$$c_0 \frac{k^2}{T} \leq \lambda_{T-k+1} \leq c_1 \frac{k^2}{T}, \quad k = 1, ..., T, \quad (C.24)$$

$$c_2 \frac{n_1^2}{m^2 T} \leq \bar{y}^* \leq c_3 \frac{n_1^2}{m^2 T}. \quad (C.25)$$

Equations (C.22) and (C.23) give one valid setting of these constants.
Upper bound on $p(\bar{y}^*)$. To upper bound $p(\bar{y}^*)$, we note that:

$$
p(\bar{y}^*) = \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{\bar{y}^*}{\lambda_t + \bar{y}^*} g_{j,t}^2 - \frac{n_1}{2}
$$

$$
= \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{\bar{y}^*}{\lambda_t + \bar{y}^*} (g_{i,j}^2 - 1) + \sum_{j=1}^{m} \sum_{t=1}^{T} \lambda_t + \bar{y}^* - \frac{n_1}{2}
$$

$$
= \sum_{j=1}^{m} \sum_{t=1}^{T} \lambda_t + \bar{y}^* (g_{i,j}^2 - 1)
$$

since $\hat{p}(\bar{y}^*) = 0$.

Therefore, by Lemma C.4,

$$
P \left( p(\bar{y}^*) > 2 \sqrt{t} \sqrt{m \sum_{t=1}^{T} \left( \frac{\bar{y}^*}{\lambda_t + \bar{y}^*} \right)^2 + 2t \max_{t=1,...,T} \frac{\bar{y}^*}{\lambda_t + \bar{y}^*}} \right) \leq e^{-t} \forall t > 0. \quad (C.26)
$$

We upper bound:

$$
m \sum_{t=1}^{T} \left( \frac{\bar{y}^*}{\lambda_t + \bar{y}^*} \right)^2 \leq m \sum_{t=1}^{T} \left( \frac{\bar{y}^*}{c_0 t^2 / T + \bar{y}^*} \right)^2 \quad \text{using (C.24)}
$$

$$
\leq m \int_{0}^{\sqrt{\frac{2c_0 T}{\bar{y}^*}}} \left( \frac{\bar{y}^*}{c_0 x^2 / T + \bar{y}^*} \right)^2 dx
$$

$$
= \frac{m(\bar{y}^*)^2 T}{2c_0 T \bar{y}^* + 2(\bar{y}^*)^2} + \frac{\sqrt{T \bar{y}^*}}{2c_0} \tan^{-1} \left( \sqrt{\frac{c_0 T}{\bar{y}^*}} \right)
$$

$$
\leq \frac{m \bar{y}^*}{2c_0} + \frac{\pi \sqrt{T \bar{y}^*}}{4\sqrt{c_0}}
$$

$$
\leq \frac{c_3}{2c_0} \frac{n_1^2}{mT} + \frac{\pi}{4} \sqrt{c_3 n_1}
$$

$$
= \left[ \frac{c_3}{128c_0} + \frac{\pi c_3}{4 \sqrt{c_0}} \right] n_1 \quad \text{using (C.25)}
$$

$$
\leq \frac{c_3}{128c_0} + \frac{\pi c_3}{4 \sqrt{c_0}} n_1 \quad \text{since } mT \geq n \text{ and } m \geq 1
$$

$$
=: c_4 n_1. \quad (C.27)
$$

Next, we immediately have:

$$
\max_{t=1,...,T} \frac{\bar{y}^*}{\lambda_t + \bar{y}^*} \leq 1. \quad (C.28)
$$

Thus, combining (C.26), (C.27), and (C.28), we have:

$$
P \left( p(\bar{y}^*) > 2 \sqrt{t_u} \sqrt{c_4 n_1} + 2t_u \right) \leq e^{-t_u} \forall t_u > 0. \quad (C.29)
$$

Lower bound on $p'(\bar{y}^*)$. Differentiating $p(y)$ yields:

$$
p'(y) = \sum_{j=1}^{m} \sum_{t=1}^{T} \frac{\lambda_t}{(\lambda_t + y)^2} g_{j,t}^2
$$
Applying Lemma C.4 yields,
\[
\mathbb{P} \left( p'(\bar{y}^*) < m \sum_{t=1}^{T} \frac{\lambda_t}{(\lambda_t + \bar{y}^*)^2} - 2\sqrt{T} \sqrt{m \sum_{t=1}^{T} \frac{\lambda_t^2}{(\lambda_t + \bar{y}^*)^4}} \right) \leq e^{-t} \quad \forall t > 0. \tag{C.30}
\]

Our first goal is to lower bound \( m \sum_{t=1}^{T} \frac{\lambda_t}{(\lambda_t + \bar{y}^*)^2} \). The function \( x \mapsto x/(x + \bar{y}^*)^2 \) is increasing when \( x \in [0, \bar{y}^*) \) and decreasing when \( x \in (\bar{y}^*, \infty) \). Let \( t^* \in \{0, \ldots, T\} \) be such that \( c_1 t^2/T \leq \bar{y}^* \) for \( t \in \{1, \ldots, t^*\} \) and \( c_1 t^2/T > \bar{y}^* \) for \( t \in \{t^* + 1, \ldots, T\} \) \( (t^* = 0 \text{ if } c_1/T > \bar{y}^*) \). We write:

\[
m \sum_{t=1}^{T} \frac{\lambda_t}{(\lambda_t + \bar{y}^*)^2} \geq \frac{c_0}{c_1} m \sum_{t=1}^{T} \frac{c_1 t^2/T}{(c_1 t^2/T + \bar{y}^*)^2}
\]

using (C.24)

\[
\begin{align*}
&= \frac{c_0}{c_1} m \left[ \sum_{t=1}^{t^*} \frac{c_1 t^2/T}{(c_1 t^2/T + \bar{y}^*)^2} + \sum_{t=t^* + 1}^{T} \frac{c_1 t^2/T}{(c_1 t^2/T + \bar{y}^*)^2} \right] \\
&\geq \frac{c_0}{c_1} m \left[ \int_0^{t^*} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx + \int_{t^* + 1}^{T + 1} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx \right] \\
&= \frac{c_0}{c_1} m \left[ \int_0^{T + 1} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx - \int_0^{t^*} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx \right].
\end{align*}
\]

The function \( z \mapsto \frac{z}{(z + \bar{y}^*)^2} \) is upper bounded by \( \frac{1}{4\bar{y}^*} \). Therefore,

\[
\int_0^{t^* + 1} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx \leq \frac{1}{4\bar{y}^*} \leq \frac{1}{4c_2} \frac{m^2T}{n_1^2}.
\]

Next,

\[
\int_0^{T + 1} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx = c_1 T \left[ \frac{1}{2c_1^{3/2}\sqrt{T}\bar{y}^*} \arctan \left( \frac{(T + 1)\sqrt{c_1}}{\sqrt{T}\bar{y}^*} \right) - \frac{T + 1}{2c_1^{3/2}(T + 1)^2 + 2c_1 T \bar{y}^*} \right] \\
\geq c_1 T \left[ \frac{m}{2c_1^{3/2}\sqrt{c_3 n_1}} \arctan \left( \frac{(T + 1)\sqrt{c_1}}{\sqrt{T}\bar{y}^*} \right) - \frac{1}{2c_1^{3/2}T} \right] \\
\geq c_1 T \left[ \frac{m}{2c_1^{3/2}\sqrt{c_3 n_1}} \arctan \left( 64\sqrt{\frac{c_1}{c_3}} - \frac{1}{2c_1^{3/2}} \right) \right].
\]

The last inequality holds because:

\[
\frac{(T + 1)\sqrt{c_1}}{\sqrt{T}\bar{y}^*} \geq (T + 1)\sqrt{\frac{c_1 m}{c_3 n_1}} \geq \sqrt{\frac{c_1 m T}{c_3 n_1}} \geq 64\sqrt{\frac{c_1}{c_3}}.
\]

Above, the first inequality holds using (C.25) and the last inequality holds since \( mT \geq n \). Therefore, assuming that \( mT \geq 2\sqrt{c_3} \frac{1}{\tan^{-1}(64\sqrt{c_1/c_3})} \frac{1}{n_1} \),

\[
\int_0^{T + 1} \frac{c_1 x^2/T}{(c_1 x^2/T + \bar{y}^*)^2} dx \geq \frac{\tan^{-1}(64\sqrt{c_1/c_3}) m T}{4\sqrt{c_1 c_3}} \frac{1}{n_1}.
\]
Combining these inequalities, assuming that \( m \leq \frac{c_{30}}{2c_{3}} \tan^{-1}(64\sqrt{c_{1}/c_{3}})n_{1} \), we have:

\[
m \sum_{t=1}^{T} \frac{\lambda_{t}}{(\lambda_{t} + \bar{y}^{*})^{2}} \geq c_{0}^{m} \left[ \frac{\tan^{-1}(64\sqrt{c_{1}/c_{3}})mT}{4\sqrt{c_{1}c_{3}}} - \frac{m^{2}T}{4c_{2}n_{1}^{2}} \right] \geq c_{0} \tan^{-1}(64\sqrt{c_{1}/c_{3}}) =: c_{5} \frac{m^{2}T}{n_{1}} \tag{C.31}
\]

Next, we turn to upper bounding \( m \sum_{t=1}^{T} \frac{\lambda_{t}^{2}}{(\lambda_{t} + \bar{y}^{*})^{4}} \). Again the function \( x \mapsto x^{2}/(x + \bar{y}^{*})^{4} \) is increasing when \( x \in [0, \bar{y}^{*}] \) and decreasing when \( x \in (\bar{y}^{*}, \infty) \), and therefore \( x^{2}/(x + \bar{y}^{*})^{4} \leq \frac{1}{16(\bar{y}^{*})^{2}} \) for all \( x > 0 \). Let \( t^{*} \in \{0, \ldots, T\} \) be such that \( c_{0}t^{*}/T \leq \bar{y}^{*} \) for \( t \in \{1, \ldots, t^{*}\} \) and \( c_{0}t^{*}/T > \bar{y}^{*} \) for \( t \in \{t^{*} + 1, \ldots, T\} \). In the case when \( c_{0}/T > \bar{y}^{*} \), we set \( t^{*} = 0 \). We have:

\[
m \sum_{t=1}^{T} \frac{\lambda_{t}^{2}}{(\lambda_{t} + \bar{y}^{*})^{4}} \leq c_{3}^{m} \left[ \sum_{t=1}^{T-1} \frac{(c_{0}t^{2}/T)^{2}}{(c_{0}t^{2}/T + \bar{y}^{*})^{4}} \right] \quad \text{using (C.24)}
\]

\[
= c_{3}^{m} \left[ \sum_{t=1}^{T-1} \frac{(c_{0}t^{2}/T)^{2}}{(c_{0}t^{2}/T + \bar{y}^{*})^{4}} + \sum_{t=t^{*}+1}^{T} \frac{(c_{0}t^{2}/T)^{2}}{(c_{0}t^{2}/T + \bar{y}^{*})^{4}} + \frac{(c_{0}(t^{*}+1)^{2}/T)^{2}}{(c_{0}(t^{*}+1)^{2}/T + \bar{y}^{*})^{4}} \right]
\]

\[
\leq c_{3}^{m} \left[ \int_{1}^{t^{*}} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx + \int_{t^{*}+1}^{T} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx + \frac{(c_{0}(t^{*}+1)^{2}/T)^{2}}{(c_{0}(t^{*}+1)^{2}/T + \bar{y}^{*})^{4}} \right]
\]

\[
\leq c_{3}^{m} \left[ \int_{0}^{T} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx + \frac{(c_{0}(t^{*})^{2}/T)^{2}}{(c_{0}(t^{*})^{2}/T + \bar{y}^{*})^{4}} + \frac{(c_{0}(t^{*}+1)^{2}/T)^{2}}{(c_{0}(t^{*}+1)^{2}/T + \bar{y}^{*})^{4}} \right]
\]

\[
\leq c_{3}^{m} \left[ \int_{0}^{T} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx + \frac{1}{8(\bar{y}^{*})^{2}} \right] \quad \text{since } \max_{x>0} \frac{x^{2}}{(x + \bar{y}^{*})^{4}} \leq \frac{1}{16(\bar{y}^{*})^{2}}
\]

\[
\leq c_{3}^{m} \left[ \int_{0}^{T} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx + \frac{1}{8c_{2}^{2}n_{1}^{4}} \right].
\]

We now bound:

\[
\int_{0}^{T} \frac{(c_{0}x^{2}/T)^{2}}{(c_{0}x^{2}/T + \bar{y}^{*})^{4}} dx = c_{3}^{T} \left[ \frac{1}{48c_{0}^{2}T\bar{y}_{*}(c_{0}T + \bar{y}^{*})^{2}} + \frac{\tan^{-1}\left( \sqrt{\frac{c_{0}T}{\bar{y}^{*}}} \right)}{16c_{0}^{5/2}T^{3/4}(\bar{y}^{*})^{3/2}} \right]
\]

\[
\leq c_{3}^{T} \left[ \frac{1}{16c_{0}\bar{y}^{*}(c_{0}T + \bar{y}^{*})^{2}} + \frac{\pi}{32c_{0}^{5/2}T^{3/4}(\bar{y}^{*})^{3/2}} \right]
\]

\[
\leq c_{3}^{T} \left[ \frac{1}{16c_{0}^{3}\bar{y}^{*}T^{2}} + \frac{\pi}{32c_{0}^{5/2}T^{3/2}(\bar{y}^{*})^{3/2}} \right]
\]

\[
\leq c_{3}^{T} \left[ \frac{1}{16c_{0}^{3}c_{2}n_{1}^{2}} + \frac{\pi}{32c_{0}^{3}c_{2}^{3/2}n_{1}^{3}} \right] \quad \text{using (C.25)}
\]

\[
\leq \left[ \frac{1}{1024c_{0}c_{2}} + \frac{\pi}{32c_{0}^{1/2}c_{2}^{3/2}n_{1}} \right] \frac{m^{3}T^{2}}{n_{1}^{3}} \quad \text{since } mT \geq n.
\]
Combining these inequalities, assuming that \( m \leq n_1 \):

\[
\sum_{t=1}^{T} \frac{\lambda_t^2}{(\lambda_t + \bar{y}^*)^4} \leq \frac{c_1^2}{c_0^2} \left[ \frac{1}{1024c_0c_2} + \frac{\pi}{8c_0^{1/2}c_2^{3/2}} \right] \frac{m^4T^2}{n_1^2} + \frac{1}{8c_2^2} \frac{m^5T^2}{n_1^2}
\]

\[
\leq \frac{c_1^2}{c_0^2} \left[ \frac{1}{1024c_0c_2} + \frac{\pi}{8c_0^{1/2}c_2^{3/2}} + \frac{1}{8c_2^2} \right] \frac{m^4T^2}{n_1^2}
\]

\( =: c_6 \frac{m^4T^2}{n_1^2} \) \hspace{1cm} \text{(C.32)}

Combining (C.30), (C.31), and (C.32) yields

\[
P \left( p'(\bar{y}^*) < c_5 \frac{m^2T}{n_1} - 2\sqrt{\ell \sqrt{c_6 m^2T}} \right) \leq e^{-\ell} \forall \ell > 0. \tag{C.33}
\]

**Lower bounds on \( y^* \).** We now combine (C.29) with (C.33) to establish a lower bound on \( y^* \). Equations (C.21) and (C.25) imply that:

\[
y^* \geq \bar{y}^* - \frac{p(\bar{y}^*)}{p'(\bar{y}^*)} = \frac{c_2n_1^2}{m^2T} - \frac{p(\bar{y}^*)}{p'(\bar{y}^*)}.
\]

We first set \( t_\ell = \frac{c_2^2}{16c_0} n_1 \), so that by (C.33),

\[
P \left( p'(\bar{y}^*) < \frac{c_5 m^2T}{2n_1} \right) \leq e^{-\frac{c_2^2}{16c_0} n_1}.
\]

We next set \( t_u = \beta n_1 \) for a \( \beta > 0 \) to be specified. By (C.29),

\[
P \left( p(\bar{y}^*) > 2(\sqrt{c_4} + \beta) n_1 \right) \leq e^{-\beta n_1}.
\]

Let \( E_2 \) denote the event:

\[
E_2 := \left\{ p'(\bar{y}^*) \geq \frac{c_5 m^2T}{2n_1} \right\} \cap \left\{ p(\bar{y}^*) \leq 2(\sqrt{c_4} + \beta) n_1 \right\}.
\]

By a union bound, \( P(E_2^c) \leq e^{-\frac{c_2^2}{16c_0} n_1} + e^{-\beta n_1} \). Furthermore,

\[
1\{E_2\} \left[ \frac{c_2n_1^2}{m^2T} - \frac{p(\bar{y}^*)}{p'(\bar{y}^*)} \right] \geq 1\{E_2\} \left[ \frac{c_2 - 4(\sqrt{c_4} + \beta)}{c_5} \right] \frac{n_1^2}{m^2T}.
\]

Setting \( \beta = c_7 := \min \left\{ \frac{c_2c_5}{16}, \frac{c_2^2}{16c_0 c_4} \right\} \), we have that \( c_2 - \frac{4(\sqrt{c_4} + \beta)}{c_5} \geq c_2/2 \), and therefore from (C.21),

\[
1\{E_1\} \bar{y}^* \geq 1\{E_1 \cap E_2\} \left[ \frac{c_2n_1^2}{m^2T} - \frac{p(\bar{y}^*)}{p'(\bar{y}^*)} \right] \geq 1\{E_1 \cap E_2\} \frac{c_2}{2} \frac{n_1^2}{m^2T}. \tag{C.34}
\]

92
Finishing the proof. Define $\mathcal{E} := \mathcal{E}_1 \cap \mathcal{E}_2$ and define $y^* := \frac{c_6 n^2}{2 m^2 T}$. By a union bound,
\[
\mathbb{P}(\mathcal{E}) \leq e^{-n/128} + e^{-mT/16} + e^{-\frac{c_6^2}{16m^2} n^2} + e^{-c_7 n^1}
\]
\[
\leq e^{-n/128} + e^{-n/16} + e^{-\frac{c_2^2}{1024 c_0^2} \frac{c_2}{64} n} + e^{-c_7 n^1}
\]
\[
\leq 4 \exp \left( - \min \left\{ \frac{1}{128}, \frac{1}{16}, \frac{c_2^2}{1024 c_0^2}, \frac{c_7}{64} \right\} n \right) =: 4e^{-c_8 n}. \tag{C.35}
\]

From (C.20), since $y^* \geq y^*$ on $\mathcal{E}$ by (C.34),
\[
1\{\mathcal{E}\} Z_i \leq 1\{\mathcal{E}\} \frac{1}{\lambda_i + y^*} \leq \frac{1}{\lambda_i + y^*}. \tag{C.36}
\]

Next, by Proposition B.2, if $n \geq 2 \max\{1, c_8^{-1}\} \log(4 \max\{1, c_8^{-1}\})$, then we have
\[
n \geq c_8^{-1} \log n \iff ne^{-c_8 n} \leq 1.
\]

We now bound,
\[
\sum_{i=1}^T \mathbb{E}[Z_i] = \sum_{i=1}^T \left[ \mathbb{E}[1\{\mathcal{E}\} Z_i] + \mathbb{E}[1\{\mathcal{E}^c\} Z_i] \right]
\]
\[
\leq \sum_{i=1}^T \left[ \frac{1}{\lambda_i + y^*} + \mathbb{P}(\mathcal{E}^c) (\Theta_{1,T,T})_{ii} \right]
\]
\[
= \sum_{i=1}^T \frac{1}{\lambda_i + y^*} + \mathbb{P}(\mathcal{E}^c) T
\]
\[
\leq \sum_{i=1}^T \frac{1}{c_0 t^2/T + y^*} + 4T e^{-c_8 n}
\]
\[
\leq \int_0^T \frac{1}{c_0 x^2/T + y^*} dx + 4T e^{-c_8 n}
\]
\[
\leq \frac{\pi}{2} \sqrt{\frac{T}{c_0 y^*}} + 4T e^{-c_8 n} = \frac{\sqrt{2} \pi}{2 \sqrt{c_0 c_2}} \frac{m T}{n_1} + 4T e^{-c_8 n}
\]
\[
\leq \left[ \frac{\sqrt{2} \pi}{2 \sqrt{c_0 c_2}} + \frac{1}{16} \right] \frac{m T}{n_1} =: c_8 \frac{m T}{n_1}
\]
\[
\text{since } ne^{-c_8 n} \leq 1 \text{ and } m \geq 1.
\]

Plugging this upper bound into (C.19):
\[
R(m, T, T'; \{P_x^f\}) \geq \sigma_2^2 \frac{1}{T} \cdot \frac{T'}{2m} \cdot \frac{n}{c_8} \cdot \frac{1}{m T} \cdot \frac{1}{256 c_8} \cdot \frac{m n^2}{m^2 T'} \cdot \frac{T'}{T}.
\]

The claim now follows. \qed
C.9 Proof of Theorem 5.3

**Theorem 5.3** (Risk lower bound). There are universal positive constants $c_0$, $c_1$, and $c_2$ such that the following holds. Recall that $P_x^n$ (resp. $P_{x^*}^{0_n \times n}$) denotes the covariate distribution for a linear dynamical system with $A = I_n$ and $B = I_n$ (resp. $A = 0_{n \times n}$ and $B = I_n$). If $T \geq c_0$, $n \geq c_1$, and $mT \geq n$, then:

$$R(m, T, T'; \{P_x^{0_n \times n}, P_x^n\}) \geq c_2 \sigma^2 \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

**Proof.** Let $\mathcal{P}_x := \{P_x^{0_n \times n}, P_x^n\}$. We let $c_0', c_1', c_2'$, and $c_3'$ denote the universal positive constants in the statement of Lemma C.14. We first invoke Lemma C.7 to conclude that:

$$R(m, T, T'; \mathcal{P}_x) \geq \frac{\sigma^2}{2} \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{T'}{T}, 1 \right\}. \quad \text{(C.37)}$$

The proof now proceeds in three cases:

**Case** $nT'/(mT) \leq 1$. In this case, we trivially have $\max \left\{ \frac{T'}{T}, 1 \right\} = \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}$. Therefore, (C.37) yields:

$$R(m, T, T'; \mathcal{P}_x) \geq \frac{\sigma^2}{2} \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

**Case** $nT'/(mT) > 1$ and $m \leq c_2' n$. In this case, we can invoke Lemma C.14 to conclude that:

$$R(m, T, T'; \mathcal{P}_x) \geq c_3' \sigma^2 \cdot \frac{pm}{mT} \cdot \frac{nT'}{mT} = c_3' \sigma^2 \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{nT'}{mT}, 1 \right\}. \quad \text{(C.38)}$$

Since $n/m \geq 1/c_2'$, we have that $nT'/(mT) \geq T'/(c_2'T)$. Therefore:

$$\max \left\{ \frac{nT'}{mT}, 1 \right\} = \max \left\{ \frac{nT'}{mT}, \frac{T'}{c_2'T}, 1 \right\} \geq \min \{1, 1/c_2' \} \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

Hence, from (C.38),

$$R(m, T, T'; \mathcal{P}_x) \geq \min \{c_3', c_3'/c_2' \} \sigma^2 \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

**Case** $nT'/(mT) > 1$ and $m > c_2' n$. In this case, we have $T'/T > c_2' nT'/(mT)$. Therefore, we have:

$$\max \left\{ \frac{T'}{T}, 1 \right\} = \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\} \geq \min \{1, c_2' \} \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

Hence, from (C.37),

$$R(m, T, T'; \mathcal{P}_x) \geq \min \{1/2, c_3'/2 \} \sigma^2 \cdot \frac{pm}{mT} \cdot \max \left\{ \frac{nT'}{mT}, \frac{T'}{T}, 1 \right\}.$$  

The claim now follows taking $c_0 = c_0'$, $c_1 = c_1'$, and $c_2 = \min \{1/2, c_3', c_3'/c_2', c_2'/2 \}$.
