Abstract

The method of instrumental variables provides a fundamental and practical tool for causal inference in many empirical studies where unmeasured confounding between the treatments and the outcome is present. Modern data such as the genetical genomics data from these studies are often high-dimensional. The high-dimensional linear instrumental-variables regression has been considered in the literature due to its simplicity albeit a true nonlinear relationship may exist. We propose a more data-driven approach by considering the nonparametric additive models between the instruments and the treatments while keeping a linear model between the treatments and the outcome so that the coefficients therein can directly bear causal interpretation. We provide a two-stage framework for estimation and inference under this more general setup. The group lasso regularization is first employed to select optimal instruments from the high-dimensional additive models, and the outcome variable is then regressed on the fitted values from the additive models to identify and estimate important treatment effects. We provide non-asymptotic analysis of the estimation error of the proposed estimator. A debiasing procedure is further employed to yield valid inference. Extensive numerical experiments show that our method can rival or outperform existing approaches in the literature. We finally analyze the mouse obesity data and discuss new findings from our method.

1 Introduction

The method of instrumental variables has been extensively used in observational studies to control for unmeasured confounding. If measurements of the treatments and the outcome are confounded by unobserved variables, the casual effects of the endogenous treatments can be identified if instrumental variables are available. The instrumental variables need to be independent of the unmeasured confounders and can only affect the outcome indirectly through the treatment variables. The method originates from early research on structural equations in econometrics [43, 1], and has become increasingly popular in biostatistics and epidemiology with Mendelian randomization as one of the most exciting recent applications [8, 9, 27, 5]. The general setting of this method involves modeling the instrument-treatment and treatment-outcome relationships. The classical two-stage least squares approach assumes linearity of both relationships and is widely used in the low-dimensional setting. However, in many concurrent studies, data are often high-dimensional. For example, gene expression data collected to identify genetic variants associated with complex traits in genome-wide association studies are usually high-dimensional. Many factors such as unmeasured environmental conditions may induce spurious associations and distort
the true relationships between the gene expressions and the outcome of interest. Nevertheless, the random assortment of the genes transferred from parents to offspring resembles the use of randomization in experiments, and single nucleotide polymorphisms (SNPs) therefore serve as natural instrumental variables. The SNPs are also high-dimensional.

Recent developments of the instrumental-variables regression have introduced regularization as a means to address the high dimensionality issue [14, 2, 10, 7, 3]. For example, [2] use the lasso to select optimal instruments from a large pool when the number of treatments remains fixed or low-dimensional. Various procedures using different types of regularization have been proposed thereafter. See [19] and [11], among others. Linear methods in which the instruments and treatments are both high-dimensional have also been considered [27, 50, 17]. [27] demonstrate an application of the high-dimensional linear instrumental-variables regression to genetic genomics. However, nonlinear effects of the SNPs on the gene expressions are likely to exist as can be seen from some recent articles that employ different kernel-based procedures to capture possible nonlinear relationships [41, 48, 46, 49]. While these methods keep fully nonparametric forms in linking the gene expressions and SNPs, they are not very effective when applied to the high-dimensional regime. [50] also considers the high-dimensional linear instrumental-variables regression for peer effect estimation in econometrics. Specifically, to analyze the effects of peers’ output on a firm’s production output using panel data, the Research and Development expenditures of peer firms from a previous period are treated as potential instrumental variables for the endogenous treatments. Nevertheless, when the linear relationships are in question, which likely are, the approach by [50] may lead to unignorable bias.

Specification of the outcome equation, either in a parametric or nonparametric form, is often based on expert knowledge or domain theory. The treatment model, however, can be more data-driven and should involve nonlinear relationships when possible to reduce bias [32, 11]. To better approximate the treatments using optimal instruments, a general nonparametric model can be beneficial. A substantial body of the recent literature on high-dimensional nonparametric estimation focuses on the additive models [see, e.g., 23, and references therein]. To this end, we consider the high-dimensional additive models to capture the nonlinear effects of the large number of instrumental variables on the treatments. We keep the linearity assumption for the outcome model so that its coefficients directly bear causal interpretations. We allow the dimensions of both the instrumental variables and the treatments to be larger than the sample size. Similar to the regularized two-stage framework for the high-dimensional linear instrumental-variables regression, our proposed procedure consists of a first stage in which we use the group lasso to select important instruments to best predict the treatments, and a second stage in which we employ lasso to regress the outcome on the first-stage predictions to perform variable selection and estimation. We provide rigorous non-asymptotic analysis of the estimator and further employ a debiasing procedure to establish valid inference.

In contrast to existing methods in the literature, the present work has the following favorable features and makes several contributions to the high-dimensional instrumental-variables regression. Firstly, the proposed procedure is more data-adaptive which allows possible nonlinear instrument-treatment relationships under high dimensions. A few recent articles from the machine learning literature adopt deep learning to better estimate the instrumental-treatment relationships [21, 44]. However, these methods typically require the dimensions of the instruments and the treatments both be smaller than the sample size, and are not directly applicable to the setting considered in the present article. Secondly, for the high-dimensional additive models in the first stage, we develop a probabilistic bound for the estimation error of the group lasso estimator. Compared with existing work in this area [e.g., 23], we explicitly derive the non-asymptotic probabilistic bounds of the estimation errors, which may be of independent interest. Similar probabilistic bounds for the estimation error of the second stage are also provided. Lastly,
we provide statistical inference for the causal parameters of interest by leveraging the debiasing procedures under high dimensionality. It is recognized that inference for high-dimensional models is typically difficult even when endogeneity is not present [24, 47, 15]. [17] consider inference in the high-dimensional linear instrumental-variables regression to deal with endogeneity. The present work goes beyond that by establishing valid inference in the more flexible additive models. Hence, our work enriches the literature on high-dimensional inference that explicitly handles endogeneity.

2 The Sparse Instrumental-Variables Model

Suppose we have \( n \) independent and identically distributed observations from a population of interest. Let \( y_i, x_i \), and \( z_i \) denote the \( i \)th observations of the outcome, the \( p \times 1 \) vector of treatment variables, and the \( q \times 1 \) vector of instrumental variables, respectively, where \( i = 1, \ldots, n \). Without loss of generality, assume the \( x_i \)'s and \( y_i \)'s are centered. Consider the following joint modeling framework:

\[
y_i = x_i^T \beta + \eta_i, \quad x_{i\ell} = \sum_{j=1}^{q} f_{j\ell}(z_{ij}) + \varepsilon_{i\ell} \quad (i = 1, \ldots, n; \ell = 1, \ldots, p),
\]

where \( \eta_i \sim N(0, \sigma^2_\eta) \) and \( \varepsilon_{i\ell} \sim N(0, \sigma^2_{\varepsilon\ell}) \). Assume the treatment variables are endogeneous in the sense that \( E(\eta_i \mid x_{i\ell}) \neq 0 \), and the instrumental variables satisfy \( E(\eta_i \mid z_{ij}) = E(\varepsilon_{i\ell} \mid z_{ij}) = 0 \). The \( f_{j\ell}(\cdot) \)'s are unknown smooth functions with compact support \([a, b]\), where \( a < b \). To ensure identifiability, assume \( E(f_{j\ell}(z_{ij})) = 0 \) for each \( i \), \( j \) and \( \ell \). This is commonly assumed in the literature on additive models. We also impose some smoothness conditions on the \( f_{j\ell}(\cdot) \)'s and set the function class of consideration to a Hölder space \( \mathcal{F} \).

Assumption 1. For \( j = 1, \ldots, q \) and \( \ell = 1, \ldots, p \), the function \( f_{j\ell} \) belongs to \( \mathcal{F} \), where

\[
\mathcal{F} = \left\{ f : |f^{(k_0)}(z') - f^{(k_0)}(z)| \leq C|z' - z|^{\alpha_0}, \quad z, z' \in [a, b]; \quad \sup_{z \in [a, b]} |f(z)| \leq C_0 \right\}
\]

with \( d = k_0 + \alpha_0 > 1.5 \) and a universal constant \( C_0 > 0 \).

This assumption is common in nonparametric regression [see, e.g., 12, 37, 23]. Other similar assumptions such as existence of high-order continuous derivatives are also widely adopted [Assumption A3, 22].

In model (1), we are mainly interested in estimating the average treatment effects, \( \beta \). The linear setting has been investigated by [27] and [50], where \( \sum_{j=1}^{q} f_{j\ell}(z_{ij}) = z_j^T \gamma_\ell \). Here, we relax the linearity assumption and embrace the more general nonparametric additive form. Define \( J_\ell = \{ j : f_{j\ell} \neq 0 \} \) for \( \ell = 1, \ldots, p \), and \( \mathcal{L} = \{ \ell : \beta_\ell \neq 0 \} \). The sparsistency assumption for the high-dimensional additive model entails that \( |J_\ell| \leq r \) for all \( \ell \) and some positive integer \( r \), where \( |J_\ell| \) denotes the cardinality of the set \( J_\ell \). Similarly, we assume \( s \)-sparsity in the second stage with \( |\mathcal{L}| \leq s \), where \( s \) is a positive integer. To rewrite model (1) in matrix form, let \( Y = (y_1, \ldots, y_n)^T \in R^n \), \( X = (x_1, \ldots, x_n)^T \in R^{n \times p} \), \( \eta = (\eta_1, \ldots, \eta_n)^T \in R^n \), \( F_j = (F_{j1}, \ldots, F_{jp}) \in R^{n \times p} \) with \( F_{j\ell} = \{ f_{j\ell}(z_{ij1}), \ldots, f_{j\ell}(z_{ijn}) \}^T \in R^n \), and \( \varepsilon = (\varepsilon_1, \ldots, \varepsilon_p) \in R^{n \times p} \) with \( \varepsilon_\ell = (\varepsilon_{1\ell}, \ldots, \varepsilon_{n\ell})^T \in R^n \) for \( j = 1, \ldots, q \) and \( \ell = 1, \ldots, p \). Then model (1) can be rewritten as

\[
Y = X\beta + \eta, \quad X = F + \varepsilon,
\]

where \( F = \sum_{j=1}^{q} F_j \). To handle high dimensionality and endogeneity, we allow \( p, q \gg n \) and develop a two-stage penalized estimation framework.
In the first stage, we estimate each univariate function \( f_{j\ell} \) via the B-spline approximation. Let \( a = \xi_0 < \xi_1 < \cdots < \xi_K < \xi_{K+1} = b \) be an equal-distanced partition of \([a,b]\), where \( K = [n^r] \) is a positive integer for some \( 0 < \nu < 0.5 \). Let \( I_{Kt} = [\xi_t, \xi_{t+1}) \) for \( t = 0, \ldots, K-1 \) and \( I_{KK} = [\xi_K, \xi_{K+1}] \). Let \( \{\phi_k(\cdot)\}_{k=1}^m \) be the normalized B-splines such that each of them is (i) a polynomial function of degree \( L \) on \( I_{Kt} \) for \( t = 0, \ldots, K \), and (ii) up to \((L-1)\) times continuously differentiable on \([a,b]\), where \( L > 1 \) is an integer and \( m = K + L \). A well-known property of such normalized basis functions is that \( 0 \leq \phi_k(z) \leq 1 \) and \( \sum_{k=1}^m \phi_k(z) = 1 \) for any \( z \in [a,b] \) [35, Theorem 4.20]. Given the \( z_{ij} \)'s, let \( \psi_{kj}(\cdot) = \phi_k(\cdot) - n^{-1} \sum_{i=1}^n \phi_k(z_{ij}) \) for \( i = 1, \ldots, n \) and \( j = 1, \ldots, q \). We will denote \( \psi_k(\cdot) = \psi_{kj}(\cdot) \) when no confusion arises. Now approximate the additive functions using \( \{\psi_k(\cdot)\}_{k=1}^m \):

\[
x_{i\ell} \approx \sum_{j=1}^q \sum_{k=1}^m \gamma_{kj\ell} \psi_k(z_{ij}) + \varepsilon_{i\ell} \quad (i = 1, \ldots, n; \ell = 1, \ldots, p).
\]

Let \( U = (U_1, \ldots, U_q) \in \mathbb{R}^{n \times qm} \), where for each \( i \) and \( j \), \( U_j = (U_{1j}, \ldots, U_{nj})^T \in \mathbb{R}^{n \times m} \) and \( U_{ij} = (\psi_1(z_{ij}), \ldots, \psi_m(z_{ij}))^T \). Further define the parameter matrix \( \Gamma = (\gamma_1, \ldots, \gamma_p) \in \mathbb{R}^{qm \times p} \), where for each \( j \) and \( \ell \), \( \gamma_{j\ell} = (\gamma_{j1\ell}, \ldots, \gamma_{jq\ell})^T \in \mathbb{R}^{qm} \) and \( \gamma_{j\ell} = (\gamma_{1j\ell}, \ldots, \gamma_{mj\ell})^T \in \mathbb{R}^{m} \). The approximation in (2) becomes \( X \approx UT + \varepsilon \).

**Lemma 1.** For each \( f_{j\ell} \in \mathcal{F} \), there exists \( \hat{\gamma}_{j\ell} = (\hat{\gamma}_{1j\ell}, \ldots, \hat{\gamma}_{mj\ell})^T \) such that with probability at least \( 1 - 2(pqm)^{-2} \), the following holds:

\[
\sup_{z \in [a,b]} |f_{j\ell}(z) - \hat{f}_{nj\ell}(z)| \leq 2C_L m^{-d} + 2C_0 \{\log(pqm)/n\}^{1/2},
\]

where \( \hat{f}_{nj\ell}(z) = \sum_{k=1}^m \hat{\gamma}_{kj\ell} \psi_k(z) \) and \( C_L \) is a universal constant depending only on \( L \).

Lemma 1 characterizes the approximation error of the centered B-splines \( \{\psi_k(\cdot)\}_{k=1}^m \) to each \( f_{j\ell}(\cdot) \) with corresponding coefficients \( \hat{\gamma}_{j\ell} \). Define \( \gamma_{\ell} = (\gamma_{1\ell}, \ldots, \gamma_{q\ell})^T \in \mathbb{R}^{qm} \). Lemma 1 implies that an intermediate step of recovering \( f_{j\ell}(\cdot) \) is to estimate \( \gamma_{\ell} \) by considering the following penalized problem:

\[
\hat{\gamma}_{\ell} = \arg\min_{\gamma_{\ell} \in \mathbb{R}^{qm}} \left\{ \frac{1}{2n} \|X_{\ell} - U \gamma_{\ell}\|_2^2 + \lambda_{\ell} \sum_{j=1}^q \|\gamma_{j\ell}\|_2 \right\} \quad (\ell = 1, \ldots, p),
\]

where \( X_{\ell} \) is the \( \ell \)th column of \( X \) and \( \lambda_{\ell} \geq 0 \) is a tuning parameter. This is a group lasso problem [45] and is motivated by the fact that when \( f_{j\ell} = 0 \), the vector \( \hat{\gamma}_{j\ell} = 0 \). After obtaining the predicted treatments \( \hat{X} = (\hat{X}_1, \ldots, \hat{X}_p) \) with \( \hat{X}_{\ell} = U \hat{\gamma}_{\ell} \), we plug \( \hat{X} \) into the following lasso problem to estimate \( \beta \) in the second stage:

\[
\hat{\beta} = \arg\min_{\beta \in \mathbb{R}^p} \left\{ \frac{1}{2n} \|Y - \hat{X} \beta\|_2^2 + \mu \|\beta\|_1 \right\}
\]

for some tuning parameter \( \mu \geq 0 \). Estimation with high-dimensional predictors has been a popular research topic in the past two decades. We note that the above formulation is slightly different from the original lasso problem due to the observed data being replaced by their estimations from the first stage. This turns out to be more involved when showing the estimation consistency.
3 Non-asymptotic analysis

In this section, we provide a probabilistic error bound for the first-stage group lasso problem. Compared with existing results in this area [23, 34], we make contributions by explicitly deriving probabilities and bounds. Based on this non-asymptotic bound, we then establish a similar probabilistic error bound for the second-stage lasso problem. Before showing these theoretical results, we define $\Sigma_U = E(U^T U/n)$ and make the following assumptions.

**Assumption 2.** Each instrumental variable $z_{ij}$ has a continuous density on $[a, b]$, which is bounded away from zero and infinity.

**Assumption 3.** There exists a universal constant $0 < \rho < 1$ such that

$$\min \left\{ \frac{\gamma^T \Sigma_U \gamma}{\|\gamma\|_2^2} : |J| \leq r, \gamma \in \mathbb{R}^{q m} \setminus \{0\}, \sum_{j \in J^c} \|\gamma_j\|_2 \leq 3 \sum_{j \in J} \|\gamma_j\|_2 \right\} \geq \frac{\rho}{m},$$

where $J \subseteq \{1, \ldots, q\}$, $J^c$ denotes the complement of $J$, and $\gamma_j = (\gamma_{j \ell} : j \in J)$.

Assumption 2 is rather standard in the literature of high dimensional additive modeling [23, 11]. Assumption 3 is often called group-wise restricted eigenvalue assumption [28, 30, 29]. This is a natural extension of the restricted eigenvalue assumption for the usual lasso and Dantzig selector problems [4]. When the instrumental variables are independent, $\Sigma_U$ is a block diagonal matrix with each block diagonal $\Sigma_j = E(U_j^T U_j/n)$. A well-known result when each instrumental variable is uniformly distributed is $\lambda_{\text{min}}(\Sigma_j) \geq c_* / m$, where $c_*$ is a constant depending on the smoothness of B-splines; see, for example, [26] and [23]. Denote $a_n = o(b_n)$ if $\lim_{n \to \infty} a_n/b_n = 0$, $a_n = O(b_n)$ if there exists a positive constant $C_1$ such that $\limsup_{n \to \infty} a_n/b_n \leq C_1$, and $a_n = \Theta(b_n)$ if there exists positive constants $C_2, C_3$ such that $C_2 \leq \inf_{n \to \infty} a_n/b_n \leq \sup_{n \to \infty} a_n/b_n \leq C_3$.

**Theorem 1.** Suppose Assumptions 1–3 hold. There exist positive constants $c_1, c_2,$ and $c_3$ such that if

$$\lambda_{\text{max}} = \max_{\ell} \lambda_{\ell} = \max \left\{ c_1 \sigma_{\text{max}} \left( \frac{\log(pqm)}{n} \right)^{1/2}, c_2 r m^{-2(2d+1)/2} + c_3 \left( \frac{\log(pqm)}{mn} \right)^{1/2} \right\},$$

then for sufficiently large $n$, with probability at least $1 - 20(pqm)^{-1}$, the regularized estimator $\hat{\gamma}_\ell$ in (3) satisfies

$$\max_{\ell} \left\| \sum_{j=1}^q F_{j \ell} - U \tilde{\gamma}_\ell \right\|_2^2 \leq \frac{50 r m n \sigma_{\text{max}}^2}{\lambda_{\text{max}}^2}, \quad \max_{\ell} \sum_{j=1}^q \left\| \tilde{\gamma}_{j \ell} - \hat{\gamma}_{j \ell} \right\|_2 \leq \frac{32 r m \sigma_{\text{max}}}{\rho},$$

where $\sigma_{\text{max}} = \max_{\ell} \sigma_{\ell}$, $m = \Theta \left( n^{1/(2d+1)} \right)$, and $r^2 = o(\{m^4 \log(pqm)\})$.

The performance of the group lasso estimator depends crucially on the eigen behavior of the empirical covariance matrix $U^T U/n$. While it can be shown that the group restricted eigenvalue condition for the empirical covariance matrix is satisfied under Assumption 3, this does come with a price on the rate of the sparsity level, that is, $r^2 = o(\{m^4 \log(pqm)\})$. Similar requirements can be found in Corollary 1 of [33]. In view of the conditions of Theorem 1, it is easy to verify that $\lambda_{\text{max}}^2 = O(r^2 \log(pqm)/n)$. Thus, to ensure the consistency of the average in-sample prediction, it is required that $r^4 = o(\{n^{2d/(2d+1)} \log(pqm)\})$, while for the estimation consistency of the coefficients, $r^4 = o(\{n^{(2d-1)/(2d+1)} \log(pqm)\})$ is required. This is a more restrictive requirement.
than that in the standard lasso, but it is expected due to the unspecified additive functional forms. In contrast to Theorem 1 of [23] that only gives the convergence rates, our result is completely non-asymptotic. Moreover, our result allows the sparsity $r$ to grow with the sample size and dimension of the data while this is not allowed in [23]. Guaranteed by Theorem 1 part (i) of [23], we can directly compare the estimation consistency result obtained here with part (ii) of their theorem, and when $r$ is a fixed number, it is easy to show they are the same. Other aligned results include [34] and [29]. [34] obtain the out-of-sample risk consistency while both the explicit rate and the in-sample error bound remain unclear. [29] consider a kernel-sieve hybrid estimator and obtain a similar non-asymptotic bound.

To provide an estimation error bound for $\hat{\beta}$ defined by (4), we make an extra assumption on the population covariance matrix $\Sigma_F = E(F^*F/n)$.

**Assumption 4.** There exists a constant $\kappa > 0$ such that
\[
\min \left\{ \frac{\beta^T \Sigma_F \beta}{\| \beta \|^2} : |L| \leq s, \beta \in \mathbb{R}^d \setminus \{0\}, \sum_{\ell \in L} |\beta_\ell| \leq 3 \sum_{\ell \in L} |\beta_\ell| \right\} \geq \kappa,
\]
where $L \subset \{1, \ldots, p\}$ and $\beta_L = (\beta_\ell : \ell \in L)$.

Assumption 4 is the restricted eigenvalue condition on $\Sigma_F$ and is useful for deriving the error bounds in the second-stage lasso problem. This assumption imposes some requirements on the covariance structures of the treatment matrix $X$ and the noise variables $\varepsilon$. For example, when $\text{cov}(\varepsilon_\ell, \varepsilon_{\ell'}) = 0$ for $\ell \neq \ell'$ and the minimum eigenvalue of $\Sigma_X = E(X^*X/n)$ is larger than $\max \sigma_\ell$, the above condition immediately holds. To provide an estimation error bound for $\hat{\beta}$, we restrict the parameter space of consideration to an $L_1$-ball $\| \beta \|_1 \leq B$ for some $B > 0$. Similar technique has been frequently used in the literature [see, e.g., 27]. This restriction can be further relaxed to the $L_\infty$-ball $\| \beta \|_\infty \leq B$, but it may lead to a sacrifice of the convergence rate.

**Theorem 2.** Suppose that Assumptions 1–4 hold. Let the regularization parameter $\lambda_{\text{max}}$ be chosen as in Theorem 1 that further satisfies $560C_0 \lambda_{\text{max}} (2r m/\rho)^{1/2} \leq \kappa^2/(4s)$. If we choose the second-stage regularization parameter
\[
\mu = 2r \lambda_{\text{max}} (7s_0 + 8\sqrt{5}B\sigma_{\text{max}} + 30B)(2m/\rho)^{1/2},
\]
then with probability at least $1 - 234(pqm)^{-1}$, the estimator $\hat{\beta}$ defined in (4) satisfies:
\[
\| \hat{\beta} - \beta \|_1 \leq \frac{64}{r^4} s_\mu, \quad \| \hat{X}(\hat{\beta} - \beta) \|_2^2 \leq \frac{64}{\kappa^2} n s_\mu^2.
\]

As far as we know, Theorem 2 is the first to present a non-asymptotic estimation error bound for the two-stage additive model. Straightforward analysis shows that consistency is guaranteed if we take $\mu^2 = O\{r^4 \log(pqm)/n^{2d/(2d+1)}\}$ and $s^2 r^3 = o\{n^{2d/(2d+1)} / \log(pqm)\}$. When $r$ is fixed, we have $s^2 = o\{n/\{m \log(pqm)\}\}$. This almost recovers the sparsity in the classical lasso setting when $d$ is large enough. Since the two-stage linear model considered by [27] and [50] is a special case of our setting, the empirical results in Section 5 demonstrate similar performance between the two models when the true relationship in both stages is linear.

### 4 Inference

In this section, we develop a method for statistical inference for each component of the outcome regression parameter vector $\beta$. When endogeneity is absent, several papers have adopted different
methods to debias the penalized estimator so that valid inference can be conducted [47, 15, 24]. A recent paper by [17] accounted for endogeneity issues and adapted the commonly-used parametric one-step update to construct confidence intervals under the high-dimensional two-stage linear models. We extend their approach to conduct statistical inference under a more general setting as considered in model (1).

The key step to derive the debiased estimator is to utilize the conditional moment restriction $E(\eta^i | Z) = 0$. This equation entails the orthogonality condition $E(\beta^T U^T \eta) = 0$. Here $\Gamma$ is any fixed coefficient matrix and we will later set $\Gamma = (\gamma_1, \ldots, \gamma_p)$. We let $D = UT$ and $d_i$ be the $i$th row of $D$. According to Lemma 1 and Theorem 1, the estimate $\hat{D} = U\hat{\Gamma}$ should be a good estimate of $D$, where $\hat{\Gamma} = (\hat{\gamma}_1, \ldots, \hat{\gamma}_p)$. Then the orthogonality condition implies its empirical counterpart based on the estimate $\hat{D}$ is approximately equal to zero; that is,

$$E_n\{h(y_i, x_i, \hat{d}_i; \beta)\} := -\hat{D}^T(Y - X\hat{\beta})/n \approx 0,$$

where $E_n(w_i) = n^{-1}\sum_{i=1}^n w_i$ for some generic variable $w$. The one-step update to the second-stage estimator $\hat{\beta}$ can be thus written as

$$\hat{\beta} = \hat{\beta} - \hat{\Omega} E_n(h(y_i, x_i, \hat{d}_i; \beta)) = \hat{\beta} + \hat{\Omega} \hat{D}^T(Y - X\hat{\beta})/n,$$

where $\hat{\Omega}$ is some estimate of $\Omega = \Sigma^{-1}$. There are two main difficulties in estimating $\Omega$ here. First, note that $\hat{D}$ is a good estimate of $F$ based on Theorem 1. One may use the empirical matrix $\hat{\Sigma}_F = \hat{D}^T\hat{D}/n$ to estimate $\Sigma_F$. However, this matrix is singular when $p > n$ and cannot be inverted to produce an estimator of $\Omega$. Second, even if an inverse were available, since the sequence of population covariance matrices $\Sigma_F$ does not itself have a limit if $p \to \infty$, one cannot naively use the continuous mapping theorem to derive asymptotic guarantees. In spirit with [17], we construct an estimator $\hat{\Omega}$ as a modification of the constrained $L_1$-minimization for inverse matrix estimation proposed in [6]. The rows $\hat{\theta}_\ell$ of the estimator $\hat{\Omega}$ are obtained as solutions to the following program:

$$\min_{\theta_\ell \in \mathbb{R}^p} \|\theta_\ell\|_1, \quad \text{subject to } \|\hat{\Sigma}_F \theta_\ell - c_\ell\|_\infty \leq \nu \quad (\ell = 1, \ldots, p),$$

(5)

where $c_\ell$ is the $\ell$th canonical basis vector in $p$ dimensions and $\nu > 0$ is a controlled tolerance. The following lemma characterizes a decomposition of the one-step update estimator $\hat{\beta}$.

**Lemma 2.** The one-step update estimator $\hat{\beta} = \hat{\beta} + \hat{\Omega} \hat{D}^T(Y - X\hat{\beta})/n$ satisfies $\sqrt{n}(\hat{\beta} - \beta) = \Omega D^T \eta/\sqrt{n} + \sum_{k=1}^4 R_k$, where

$$R_1 = (\hat{\Omega} - \Omega) D^T \eta/\sqrt{n}, \quad R_2 = \hat{\Omega} (\hat{D} - D)^T \eta/\sqrt{n},$$

$$R_3 = \hat{\Omega} \hat{D}^T(X - D)(\beta - \hat{\beta})/\sqrt{n}, \quad R_4 = \sqrt{n}(\hat{\Omega} \hat{\Sigma}_F - I)(\beta - \hat{\beta}).$$

Lemma 2 implies that to establish asymptotic normality of each component $\tilde{\beta}_k$, it suffices to guarantee each remainder term $R_k = o_p(1)$ under some conditions. The $L_1$-bound for $\hat{\theta}_\ell - \theta_\ell$, which we require for controlling the remainder terms, depends on the following restriction on the class of population precision matrices.

**Assumption 5.** There exist some positive number $m_\Omega$, the controlled tolerance $b \in [0, 1)$, and the generalized sparsity level $s_\Omega$ such that the population precision matrix $\Omega \in U(m_\Omega, b, s_\Omega)$, where

$$U(m_\Omega, b, s_\Omega) = \left\{ \Omega = (\theta_{\ell \ell'})_{\ell,\ell' = 1}^p > 0 : \|\Omega\|_1 \leq m_\Omega; \max_{\ell \in \{1, \ldots, p\}} \sum_{\ell' \in \{1, \ldots, p\}} |\theta_{\ell \ell'}|^b \leq s_\Omega \right\},$$

and $\|\Omega\|_1 = \sup_{\ell} \|\theta_\ell\|_1$. 

7
For high-level conditions, we assume that the probability that the rows \( \theta_\ell \) of the population precision matrix \( \Omega \) are feasible for the minimization program (5) approaches one. To express this requirement in a formal way, we require that \( \text{Pr}(\|\Omega\Sigma_F - I\|_\infty \leq \upsilon) \to 1 \) as \( n \to \infty \). The validity of such a requirement mainly depends on choices of the controlled tolerance \( \upsilon \). We give a theoretical choice for \( \upsilon \) in Theorem 3 and provide some rate conditions under which \( \sqrt{n}(\hat{\beta}_\ell - \beta_\ell)/\omega_\ell \) converges in distribution to the standard normal random variable, where \( \omega_\ell^2 = \sigma_0^2 \theta_\ell \ell \) and \( \theta_\ell \ell \) is the \( \ell \)-th diagonal of \( \Omega \).

**Theorem 3.** Suppose that Assumptions 1–5 and the conditions in Theorems 1–2 hold. We also assume that each element \( \theta_\ell \) > \( \vartheta \) for some universal constant \( \vartheta > 0 \) and choose \( \upsilon = 36C_0m\lambda_{\max}(2rn/p)^{1/2} \). If the following rate conditions

\[
\begin{align*}
& r^{(7-5b)/2} \left\{ \frac{\log(pqm)}{n} \right\}^{(1-b)/2} \left[ m^{1/2} + \{ \log(pqm) \}^{1/2} \right] = o(1), \\
& r^2 \left( m^3/n \right)^{1/2} \log(pqm) = o(1), \\
& r^{7/2} s \left( m^2/n \right)^{1/2} \log(pqm) = o(1),
\end{align*}
\]

hold, then each remainder term in Lemma 2 satisfies \( \| \tilde{R}_\ell \|_\infty = o_p(1) \). Moreover, \( \sqrt{n}(\tilde{\beta}_\ell - \beta_\ell)/\omega_\ell \) converges in distribution to the standard normal distribution.

The rates we assume in Theorem 3 is mainly required to control the remainder terms so that they are negligible. When the sparse parameter in first stage \( r \) remains fixed, we observe that the requirement for the sparsity level of second stage \( s = o(n^{1/2}m/\log(pqm)) \) is almost same with the usual requirement of debias lasso result \( s = o(n^{1/2}/\log(p)) \) see \([24, 15]\). With this theorem, one can construct the confidence interval if a consistent estimator \( \hat{\omega}_\ell \) is available. Given \( \ell \in \{1, \ldots, p\} \) and \( \alpha \in (0, 1) \), an asymptotic 100(1–\( \alpha \))% confidence interval is \([\hat{\beta}_\ell - z_\alpha \hat{\omega}_\ell/n^{1/2}, \hat{\beta}_\ell + z_\alpha \hat{\omega}_\ell/n^{1/2}]\), where \( z_\alpha = \Phi^{-1}(1-\alpha/2) \). We now provide one way to construct a consistent estimator \( \hat{\omega}_\ell \).

**Theorem 4.** Suppose the conditions in Theorem 1–3 hold, and define

\[
\hat{\omega}_\ell = \hat{\sigma}_0 \left( \hat{\alpha}^T \hat{U}^T U \hat{\alpha}/n \right)^{1/2}, \quad \text{where} \quad \hat{\sigma}_0 = n^{-1/2} \| Y - X \hat{\beta} \|_2.
\]

Then \( \hat{\omega}_\ell \) is a consistent estimator of \( \omega_\ell \) for each \( \ell \in \{1, \ldots, p\} \).

## 5 Simulation

In this section, we conduct simulation studies to evaluate the finite sample performance of the proposed estimators. Our objective is to test both the estimation and inferential procedures under a variety of experiments. For estimation, we compare our procedure with the classical one-stage penalized least squares (PLS) with lasso and the two-stage regularized (2SR) method [27]. For inference, we use the method proposed by [17] for comparison.

We first investigate the estimation performance of the proposed method and design two settings where endogeneous treatments are generated respectively from linear and nonlinear treatment models. In both settings, we take \( p = q = 600 \) and vary \( n \) from 100 to 2100 so that both high-dimensional and low-dimensional cases are covered. We generate instrumental variables \( z_i \) of the \( i \)-th sample from the multivariate normal distribution with zero mean and covariance matrix \( \Sigma_Z = \{ (\Sigma_Z)_{jj'} \} \), where \( (\Sigma_Z)_{jj'} = 0.2^{|j-j'|} \) for \( j, j' = 1, \ldots, q \). To generate the noise vector \( (\eta_1, \varepsilon_{11}, \ldots, \varepsilon_{1p})^T \), we sample from another normal distribution with zero mean and covariance matrix \( \Sigma = (\Sigma_\ell \ell) \) where \( \Sigma_\ell \ell = 0.2^{(\ell-\ell')} \) for \( \ell, \ell' = 2, \ldots, p+1 \) and \( \Sigma_11 = 1 \); in addition to the five \( \Sigma_\ell \ell \)'s \( (\ell = 2, \ldots, 6) \), five another nonzero entries are sampled from the first
column of Σ; we set these ten elements to 0.3 and other remaining elements to zero; we finally let Σ_{1\ell} = Σ_{\ell1} for ℓ = 2, \ldots, p + 1. Note that the nonzero Σ_{1\ell}'s are used to cause endogeneity issues. In linear model settings, we generate treatment variables x_i according to $x_i = \Gamma^* z_i + \varepsilon_i$, where Γ = (γ_{j\ell}) ∈ R^{q×p} is a sparse coefficient matrix that is obtained by sampling r = 5 nonzero entries of each column from the uniform distribution U(0, 0.75, 1). In the nonlinear setting, we generate $x_i$ from the following equation:

$$x_i\ell = γ_{1\ell} z_{i1}^2 + γ_{2\ell} z_{i2} + γ_{3\ell} z_{i3}^2 + γ_{4\ell} \sin(π z_{i4}) + γ_{5\ell} z_{i5}^2 + \varepsilon_i, \quad (ℓ = 1, \ldots, p).$$

The sampling strategy for the coefficients γ_{j\ell}'s are the same with that in linear setting. We finally generate outcome data according to $y_i = x_i^T \beta + η_i$, where the coefficient vector β is generated by sampling s = 5 nonzero components from the uniform distribution $U\{(−1, −0.75) \cup (0.75, 1)\}$.

In all simulations, we use BIC rule to select the first-stage tuning parameters m and λ_ℓ’s, and apply 5-fold cross validation to select the second-stage regularization parameter μ. We report the $L_1$ estimation loss $||\hat{β} - β||_1$ of each method based on 100 replications. The results are summarized in Table 1. It can be seen that when the instrument-treatment relationship is linear, the proposed method generally has as good performance as 2SR. Specifically, as sample size increases, the $L_1$ estimation losses of both methods decrease, whereas the PLS method without considering endogeneity performs worse. When the instrument-treatment relationship is nonlinear, the results of the proposed method are similar with those in the linear setting. The $L_1$ estimation loss of our method is smallest in almost all settings and still exhibits the decreasing trend as sample size increases. In contrast, neither of the two existing methods share such performance trends in this setting. It seems that the impact of model misspecifications on 2SR is heavier than that on PLS. This is not general and may be specific to this simulation setting. Overall, the results in Table 1 demonstrate the estimation consistency of our estimator.

Table 1: $L_1$ estimation loss of each method averaged over 100 replications with standard deviation shown in parentheses for p = 600.

| Sample | Linear | | | | Nonlinear | | | |
|---|---|---|---|---|---|---|---|
| | Proposed | 2SR | PLS | | Proposed | 2SR | PLS |
| 100 | 1.26 (0.53) | 2.52 (1.19) | 0.86 (0.22) | 2.96 (1.41) | 1.19 (0.38) | 1.25 (0.38) |
| 300 | 0.50 (0.23) | 0.59 (0.30) | 0.51 (0.16) | 0.74 (0.28) | 1.27 (0.79) | 0.79 (0.27) |
| 600 | 0.34 (0.15) | 0.27 (0.11) | 0.46 (0.17) | 0.43 (0.17) | 1.73 (1.26) | 0.89 (0.27) |
| 900 | 0.25 (0.10) | 0.23 (0.08) | 0.52 (0.14) | 0.32 (0.13) | 2.90 (1.98) | 1.10 (0.23) |
| 1200 | 0.19 (0.09) | 0.19 (0.08) | 0.61 (0.18) | 0.27 (0.13) | 3.35 (2.36) | 1.18 (0.18) |
| 1500 | 0.17 (0.08) | 0.18 (0.08) | 0.70 (0.25) | 0.24 (0.10) | 4.17 (3.29) | 1.27 (0.16) |
| 1800 | 0.16 (0.07) | 0.17 (0.08) | 0.81 (0.29) | 0.21 (0.09) | 4.74 (4.03) | 1.34 (0.17) |
| 2100 | 0.14 (0.05) | 0.16 (0.07) | 1.09 (0.42) | 0.21 (0.11) | 5.61 (4.38) | 1.43 (0.16) |

We next evaluate the performance of the inferential procedure proposed in Section 4 and consider a more challenging nonlinear setting as follows:

$$x_{i\ell} = −8γ_{1\ell} z_{i1}^2 + γ_{2\ell} \sin(π z_{i2}) + 2γ_{3\ell} \log(z_{i3}^2) + γ_{4\ell}(10 z_{i4})^3 + γ_{5\ell} z_{i5}^2 + \varepsilon_i, \quad (ℓ = 1, \ldots, p).$$

We calculate the 95% confidence interval of each element of β based on the proposed estimator and the estimator proposed by [17]. The coverage probabilities and confidence interval length averaged over all elements are shown in Table 2. The proposed estimator based confidence intervals
have coverage probabilities close to the nominal level of 0.95. In contrast, the confidence intervals based on the estimator proposed by [17] have coverage probabilities well below the nominal level. Moreover, their interval lengths are much wider than ours in all settings. These results are as expected, because the inferential procedure by [17] is proposed in the high-dimensional linear instrumental-variable model setting and may not perform well in the current nonlinear setting. The results in Table 2 validate the theoretical results on inference.

Table 2: Coverage probability and length of the 95% confidence interval for the proposed method and the method by [17]; values have been multiplied by 100.

6 Real Data Analysis

We illustrate the proposed method by reanalyzing the mouse obesity dataset described by [40]. The data set consists of genotypes, gene expressions and clinical information of the F2 intercross mice. The genotypes are characterized by SNPs at an average density of 1.5 cM across the whole genome and the gene expressions are profiled on microarrays in the liver tissues of the mice. We are interested in the causal effect of gene expressions on the body weight of the mice. Following [27], we focus on the data collected from \( n = 287 \) (144 female and 143 male) mice with \( q = 1250 \) SNPs and \( p = 2816 \) genes. Since there are only three genotypes, high-dimensional linear models between SNPs and gene expressions are often postulated. However, some recent papers suspected that nonlinear effects may exist [25, 48, 18]. This has motivated us to consider the current setting and we have proposed a method that can handle possible nonlinear relationships. Before using our method, we need to adjust for confounding induced by sex of mice. We first fit a linear regression model between sex and body weight of mice, and subtract the estimated effect from the body weight. We then apply the proposed method with the adjusted body weight as the outcome. We use 10-fold cross-validation to select tuning parameters and the resulting model includes 28 genes. In order to increase the stability and interpretability of our analysis, we apply the stability selection approach proposed by [31] to compute the selection probability of each gene over 100 subsamples of size \( \lfloor n/2 \rfloor \) for a sequence of tuning parameters \( \mu \). Following [27], we set the threshold probability to be 0.5, and the corresponding results are shown in Table 3.

It is interesting to compare our analysis result with that given in [27]. We observe that there are 5 genes overlapped with theirs, which are Igfbp2, Gstm2, Wvf, 2010002N04Rik, and Ccnl2. As argued in [27], these overlapping genes are highly likely to connect with obesity from a biological point of view. This also indicates the effectiveness and stability of our method on analysis of the real data set. Table 3 shows that our method also identifies some other genes that were not found in [27], since we consider a nonparametric function form instead of a linear model in the first stage. In fact, some genes selected with high probability as have been verified by many biological studies. In particular, Solute Carrier Family 43 Member 1 (Sle43a1) is a Protein Coding gene that can encode the amino acid transporters that are known to regulate the transmembrane transport of phenylalanine. [16] found that the expression of Sle43a1 is quite
Table 3: Stability selection: the selected genes with superscript “*” denote the ones overlapping with 2SR [Table 3, 27].

different in fat mice group compared with that in lean mice group and Scl43a1 is a potential factor leading to obesity.

Another analysis on this data we perform is to apply the inference procedure established in this paper. We use the R package Flare to obtain the optimal precision matrix, which is a practical implementation of the program (5). Then we can establish the confidence interval based on the debiased estimator. Table 4 presents the causal effect of genes on the body weight whose confidence interval does not contain zero. Notice the confidence interval is wide, which may be due to the low signal-to-noise ratio of gene data or small sample size. The result is generally consistent with that obtained by stable selection. The confidence intervals that are far away from zero include Vwf, 2010002N04Rik, Gstm2, Gpld1, Scl43a1, Igfbp2, which are also shown to have high selection probability in both our result (Table 3) and the result of [27]. Moreover, several other genes that are shown to have significant causal effect on the body weight of mice are newly found based on Table 4 and have been confirmed to have close biological relation with obesity. For example, a recent study in [42] shows that by silencing Anxa2, the obesity-induced insulin resistance is attenuated and our result confirms such positive relation. Cyp4f15 genes control the omega-hydroxylated fatty acids in liver tissue, which can be metabolized and used for energy production [20]. Another independent study shows that the downregulation of Cyp4f15 happens in the liver tissue among the group of mice fed with high-fat diet [13]. The negative causal effect obtained in our result coincides with this finding.

Table 4: 95% confidence intervals for the causal effects of the genes on the body weights of the mice. Shown are only the genes whose corresponding intervals do not contain zero.

Appendix

We provide all of the proofs for the results in the main text and additional numerical experiments.

A Proof of Theoretical Results

We first define the notation that will be used throughout the supplement. Suppose $A \in \mathbb{R}^{m \times n}$. Let $\|A\|_2$ be the largest singular value of $A$ and $\|A\|_\infty$ the largest absolute value of the entries of $A$. Also, let $\|A\|_1 = \max_{j \in [n]} \|A_j\|_1$, where $A_j$ is the $j$th column of $A$ and $[n] = \{1, \ldots, n\}$. Denote by $\lambda_{\min}(A)$ and $\lambda_{\max}(A)$ the minimum and maximum eigenvalues of $A$, respectively, when $A$ is symmetric.

A.1 Some Useful Lemmas

**Lemma 3** (Hoeffding Bound, Proposition 2.5 in [39]). Suppose random variables $X_i, i = 1, \ldots, n$ are independent, and $X_i$ has mean $\mu_i$ and sub-Gaussian parameter $\sigma_i$. Then for all $t \geq 0$, we have

$$\mathbb{P}\left\{ \left| \frac{1}{n} \sum_{i=1}^{n} (X_i - \mu_i) \right| \geq t \right\} \leq 2 \exp \left( - \frac{n^2 t^2}{2 \sum_{i=1}^{n} \sigma_i^2} \right).$$

Specifically, if $X_i$ is bounded in $[a, b]$, we have

$$\mathbb{P}\left\{ \left| \frac{1}{n} \sum_{i=1}^{n} (X_i - \mu_i) \right| \geq t \right\} \leq 2 \exp \left( - \frac{2nt^2}{(b-a)^2} \right).$$

Lemma 4 follows from Lemma 5 of [37], which is a well-known approximation result for B-splines and has been frequently used in additive models.

**Lemma 4.** For each $f_{jt} \in \mathcal{F}$, there exists $\tilde{f}_{njt} = \sum_{k=1}^{m} \hat{g}_{kjt} \phi_k$ such that $\sup_{z \in [a, b]} |f_{jt}(z) - \tilde{f}_{njt}(z)| \leq C_L m^{-d}$, where $C_L$ is a constant depending only on the B-spline degree $L$.

The next result shows that the minimum and maximum eigenvalues of the spline matrices have the same order. Denote the uncentered B-spline matrix by $\tilde{U} = (\tilde{U}_1, \ldots, \tilde{U}_q) \in \mathbb{R}^{n \times qm}$, where $\tilde{U}_j = (\tilde{U}_{1j}, \ldots, \tilde{U}_{nj})^T \in \mathbb{R}^{n \times m}$ and $\tilde{U}_{ij} = \{\phi_1(Z_{ij}), \ldots, \phi_m(Z_{ij})\}^T \in \mathbb{R}^m$.

**Lemma 5** (Lemma 6.2 in [36]). For $j = 1, \ldots, q$, we have

$$3c_a/m - 2\|P_j - P_j^n\|_\infty \leq \lambda_{\min}(\tilde{U}_j^T \tilde{U}_j/n) \leq \lambda_{\max}(\tilde{U}_j^T \tilde{U}_j/n) \leq c^*/2m + 2\|P_j - P_j^n\|_\infty,$$

where $c_a < 1 < c^*$, $P_j$ and $P_j^n$ being the population and empirical distributions of $Z_j$, respectively.

The following result gives a bound on $\|P_j - P_j^n\|_\infty$.

**Lemma 6** (Glivenko–Cantelli Theorem, Corollary 4.15 in [38]). Let $F(t) = \mathbb{P}(X \leq t)$ be the cumulative distribution function (CDF) of a random variable $X$ and $F_n$ the empirical CDF based on $n$ i.i.d. copies, $X_1, \ldots, X_n$, of $X$. Then, we have

$$\|P_n - P\|_\infty \leq 8\left(\log(n+1)/n\right)^{1/2} + \delta$$

with probability at least $1 - \exp(-n\delta^2/2)$ for all $\delta \geq 0$. 

16
Combining Lemmas 5 and 6, we obtain the following result on the B-spline matrix.

**Lemma 7.** If \( 8 \log(n+1)/n + (2/m^3)^{1/2} \leq \min\{c_s/m, c^*/4m\} \), then for each \( j = 1, \ldots, q \), with probability at least \( 1 - \exp(-nm^{-3}) \), we have
\[
c_s/m \leq \lambda_{\min}(\tilde{U}^T_j \tilde{U}_j/n) \leq \lambda_{\max}(\tilde{U}^T_j \tilde{U}_j/n) \leq c^*/m.
\]

**Proof.** Apply the Glivenko–Cantelli Theorem (Lemma 6) with \( \delta = \sqrt{2/m^3} \).

**Lemma 8** (Bernstein’s Inequality, Proposition 2.14 in [39]). Let \( X_1, \ldots, X_n \) be i.i.d. random variables such that \( |X_i| \leq b \) almost surely for some positive number \( b \). Then for any \( \delta > 0 \), we have
\[
\left| \frac{1}{n} \sum_{i=1}^{n} \{X_i - \mathbb{E}(X_i)\} \right| \leq \delta
\]
holds with probability at least \( 1 - 2 \exp[-n\delta^2/(2(b^2 + \delta^2))] \).

**Lemma 9** (Concentration Inequality for \( \chi^2 \) Variable, Example 2.11 in [39]). Suppose \( X_1, \ldots, X_n \) are i.i.d. standard normal random variables. Then for \( t \geq 0 \), we have
\[
\mathbb{P}\left( \frac{1}{n} \sum_{i=1}^{n} X_i^2 - 1 \geq t \right) \leq 2 \exp\left(-nt^2/8\right).
\]

We present a key concentration result which will be used in our proofs.

**Lemma 10** (Lemma B.1 in [28]). Let \( \xi_1, \ldots, \xi_N \) be i.i.d. standard normal random variables. Also, let \( v = (v_1, \ldots, v_N) \neq 0 \), \( \eta_v = \sum_{i=1}^{N} (\xi_i^2 - 1)v_i/(\sqrt{2}\|v\|_2) \) and \( m(v) = \|v\|_{\infty}/\|v\|_2 \). Then for all \( x > 0 \), we have
\[
\mathbb{P}(\|\eta_v\| > x) \leq 2 \exp\left[-\frac{x^2}{2\{1 + \sqrt{2}m(v)\}}\right].
\]

The following lemma validates that the restricted eigenvalue condition holds with high probability when Assumption 3 holds.

**Lemma 11.** Suppose Assumption 3 holds. With probability at least \( 1 - 6(qm)(pqm)^{-2} \), we have
\[
\min \left\{ \gamma^T U^T U \gamma/n : |J| \leq r, \gamma \in \mathbb{R}^{qm}\{0\}, \sum_{j \in J^c} \|\gamma_j\|_2 \leq 3 \sum_{j \in J} \|\gamma_j\|_2 \right\} \geq \frac{\rho}{2m}.
\]

if \( 160r\{m^4 \log(pqm)/n\}^{1/2} \leq \rho/2 \).

**Proof.** Note that
\[
\Sigma = \frac{U^T U}{n} = \frac{n - 1}{n} \mathbb{E} \left\{ \tilde{U} - \mathbb{E}(\tilde{U}) \right\}^T \left\{ \tilde{U} - \mathbb{E}(\tilde{U}) \right\} n + \frac{\mathbb{E}(\tilde{U})^T \mathbb{E}(\tilde{U})}{n} + \frac{\tilde{U}^T 11^T \tilde{U}}{n^2} - \frac{\mathbb{E}(\tilde{U})^T \tilde{U}}{n} - \frac{\tilde{U}^T \mathbb{E}(\tilde{U})}{n}.
\]
Let \( \hat{\Sigma} = \mathbb{E}[(\hat{U} - \mathbb{E}(\hat{U}))^T(\hat{U} - \mathbb{E}(\hat{U}))]/n \). Then, we have

\[
\| \Sigma - \frac{U^* U}{n} \|_\infty \leq \left\| \frac{n-1}{n} \Sigma - \frac{(U - \mathbb{E}(\hat{U}))^T(U - \mathbb{E}(\hat{U}))}{n} \right\| + \left\| \frac{\mathbb{E}(U)^T \mathbb{E}(U)}{n} - \frac{\hat{U}^* \mathbb{E}(\hat{U})}{n} \right\|_\infty
\]

\[
+ \left\| \frac{\hat{U}^* 11^T \hat{U}}{n^2} - \frac{\mathbb{E}(U)^T \hat{U}}{n} \right\| = T_1 + T_2 + T_3.
\]

For \( T_2 \), we can write

\[
T_2 = \left\| \frac{\mathbb{E}(\hat{U})^T \mathbb{E}(\hat{U})}{n} - \frac{\hat{U}^* \hat{U}}{n} \right\|_\infty = \left\| \mathbb{E}(\hat{U})^T (\mathbb{E}(\hat{U}) - \frac{\hat{U}^* \hat{U}}{n}) \right\|_\infty
\]

\[
= \max_{j,j',k,k'} \left| \mathbb{E}\{\phi_k(Z_{ij})\} \mathbb{E}\{\phi_{k'}(Z_{ij'})\} - \frac{n}{n} \sum_{i=1}^{n} \phi_k(Z_{ij}) \mathbb{E}\{\phi_{k'}(Z_{ij'})\} \right|
\]

\[
\forall j,j' \in \{1, \ldots, q\}, k,k' \in \{1, \ldots, m\},
\]

where \( \hat{U}_{ij}^* \) is the \( i \)th row of \( U \). By the property of the B-spline matrix, we have \( 0 \leq \phi_k(z) \leq 1 \) and \( 0 \leq \mathbb{E}\{\phi_k(Z_{ij})\} \leq 1 \). Therefore,

\[
T_2 = \left\| \frac{\mathbb{E}(\hat{U})^T \mathbb{E}(\hat{U})}{n} - \frac{\hat{U}^* \mathbb{E}(\hat{U})}{n} \right\|_\infty \leq \max_{j,j',k,k'} \left| \mathbb{E}\{\phi_k(Z_{ij})\} - \frac{n}{n} \sum_{i=1}^{n} \phi_k(Z_{ij}) \right|
\]

Now apply Lemma 3 with \( t = \{4 \log(pqm)/n\}^{1/2} \) and take the union bound to obtain

\[
T_2 = \left\| \frac{\mathbb{E}(\hat{U})^T \mathbb{E}(\hat{U})}{n} - \frac{\hat{U}^* \mathbb{E}(\hat{U})}{n} \right\|_\infty \leq \left\{ \frac{4 \log(pqm)}{n} \right\}^{1/2},
\]

which holds with probability at least \( 1 - 2(qm)(pqm)^{-2} \). For \( T_3 \), the same bound can be obtained with the same probability since

\[
T_3 = \left\| \frac{\hat{U}^* 11^T \hat{U}}{n^2} - \frac{\mathbb{E}(U)^T \hat{U}}{n} \right\|_\infty
\]

\[
= \max_{j,j',k,k'} \left| \frac{\sum_{i=1}^{n} \phi_k(Z_{ij}) \phi_{k'}(Z_{ij'})}{n} - \mathbb{E}\{\phi_k(Z_{ij})\} \right| \left| \frac{\sum_{i=1}^{n} \phi_{k'}(Z_{ij'})}{n} - \mathbb{E}\{\phi_{k'}(Z_{ij'})\} \right|
\]

\[
\leq \max_{j,j',k,k'} \left| \frac{\sum_{i=1}^{n} \phi_{k'}(Z_{ij'})}{n} - \mathbb{E}\{\phi_{k'}(Z_{ij'})\} \right|
\]

Now we bound \( T_1 \)

\[
T_1 = \left\| \frac{n-1}{n} \Sigma - \frac{(\hat{U} - \mathbb{E}(\hat{U}))^T(\hat{U} - \mathbb{E}(\hat{U}))}{n} \right\|_\infty
\]

\[
\leq \left\| \Sigma - \frac{(\hat{U} - \mathbb{E}(\hat{U}))^T(\hat{U} - \mathbb{E}(\hat{U}))}{n} \right\|_\infty + \frac{1}{n} \left\| \Sigma \right\|_\infty
\]

\[
\leq \max_{j,j',k,k'} \left| \mathbb{E}\{\phi_k(Z_{ij})\} \phi_{k'}(Z_{ij'}) - \mathbb{E}\{\phi_k(Z_{ij})\} \right| \left| \mathbb{E}\{\phi_{k'}(Z_{ij'})\} - \mathbb{E}\{\phi_{k'}(Z_{ij'})\} \right| \left| \frac{n}{n} \sum_{i=1}^{n} \phi_k(Z_{ij}) \phi_{k'}(Z_{ij'}) \right| + \frac{1}{n} \sum_{i=1}^{n} \left| \phi_k(Z_{ij}) \right| \left| \phi_{k'}(Z_{ij'}) \right| + \frac{2}{n},
\]

18
where the last inequality holds because each entry of $\tilde{\Sigma}$ can be bounded

$$|\mathbb{E}\{\phi_k(Z_{ij})\phi_k(Z_{ij'})\} - \mathbb{E}\{\phi_k(Z_{ij})\} \mathbb{E}\{\phi_k(Z_{ij'})\}| \leq |\mathbb{E}\{\phi_k(Z_{ij})\phi_k(Z_{ij'})\}| + |\mathbb{E}\{\phi_k(Z_{ij})\} \mathbb{E}\{\phi_k(Z_{ij'})\}| \leq 2.$$  

Note $|\phi_k(Z_{ij}) - \mathbb{E}\{\phi_k(Z_{ij})\}| \leq 1, \forall j \in \{1, \ldots, q\}, k \in \{1, \ldots, m\}$, so we have

$$|\phi_k(Z_{ij}) - \mathbb{E}\{\phi_k(Z_{ij})\} - \mathbb{E}\{\phi_k(Z_{ij'})\}| \leq 1.$$  

Applying Lemma 3 again with $t = \{8 \log(pqm)/n\}^{1/2}$, we obtain by the union bound argument over $j, j' \in \{1, \ldots, q\}, k, k' \in \{1, \ldots, m\}$

$$T_1 \leq \{8 \log(pqm)/n\}^{1/2} + 2/n \leq 6\{\log(pqm)/n\}^{1/2}, \quad \text{(6)}$$

which holds with probability at least $1 - 2(qm)^2(pqm)^{-4}$. Thus, we have

$$\left\|\Sigma - \frac{U^* U}{n}\right\| \leq T_1 + T_2 + T_3 \leq 10\left\{\frac{\log(pqm)}{n}\right\}^{1/2},$$

which holds with probability at least $1 - 6(qm)^2(pqm)^{-2}$. Consider $\gamma$ such that $\sum_{j \in J} \|\gamma_j\|_2 \leq 3 \sum_{j \in J} \|\gamma_j\|_2$, then by Assumption 3, we have

$$\frac{\gamma^TU^* U\gamma}{n} = \gamma^T U^* U \frac{\gamma}{n} - \gamma^T \Sigma \gamma + \gamma^T \Sigma \gamma \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \left\|\gamma^T U^* U \frac{\gamma}{n}\right\| - \gamma^T \Sigma \gamma \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} \left(\sum_{j \in J} \|\gamma_j\|_1 + \sum_{j \in J} \|\gamma_j\|_1\right)^2 \left\|\Sigma - \frac{U^* U}{n}\right\| \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} \left(\sum_{j \in J} \|\gamma_j\|_2 + 3 \sum_{j \in J} \|\gamma_j\|_2\right)^2 \left\|\Sigma - \frac{U^* U}{n}\right\| \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} \left(\sum_{j \in J} \|\gamma_j\|_2\right)^2 \left\|\Sigma - \frac{U^* U}{n}\right\| \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} \left(\sum_{j \in J} \|\gamma_j\|_2\right)^2 \left\|\Sigma - \frac{U^* U}{n}\right\| \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} \left(\sum_{j \in J} \|\gamma_j\|_2\right)^2 \left\|\Sigma - \frac{U^* U}{n}\right\|.$$  

It follows from (6) that

$$\frac{\gamma^TU^* U \gamma}{n} \geq \frac{\rho}{m} \frac{\|\gamma_j\|_2^2}{m} - 160rmn\|\gamma_j\|_2^2 \left\{\frac{\log(pqm)}{n}\right\}^{1/2} \geq \frac{\|\gamma_j\|_2^2 \rho}{2m}$$

holds with probability at least $1 - 6qm(pqm)^{-2}$, as long as $160\{m^4 \log(pqm)/n\}^{1/2} \leq \rho/2$. This concludes the lemma.

We first give a Lemma which will be fundamental for proving Theorem 1.

19
Lemma 12. For every \( j \in \{1, \ldots, q\} \), we consider the random event

\[
\mathcal{A}_\ell = \cap_{j=1}^q A_{j\ell}
\]

where

\[
A_{j\ell} = \left\{ \frac{1}{n} \| U_j^T \varepsilon_\ell \|_2 \leq \frac{\lambda_{1\ell}}{4} \right\}
\]

If \( \lambda_{1\ell} \) chosen to be

\[
\lambda_{1\ell} \geq \frac{4\sigma_\ell \epsilon^*}{n^{1/2} (14 \log(pqm))^{1/2}}, \quad \ell = 1, \ldots, p
\]

then \( \mathbb{P}(\mathcal{A}_\ell^c) \leq 3(pqm)^{-2}q. \)

Proof. Note that

\[
\mathbb{P}(A_{j\ell}) = \mathbb{P}\left( \frac{1}{n^2} \varepsilon_\ell^T U_j U_j^T \varepsilon_\ell \leq \frac{\lambda_{1\ell}^2}{16} \right) = \mathbb{P}\left\{ \sum_{i=1}^n \nu_{j,i} (\xi_i^2 - 1) \leq \frac{1}{\sqrt{2}} \| \nu_j \|_2 \right\},
\]

where \( \xi_1, \ldots, \xi_n \) are i.i.d standard normal random variables, \( \nu_{j,1}, \ldots, \nu_{j,n} \) denote the eigenvalues of the matrix \( U_j U_j^T / n \) among which the positive ones are the same as those of \( \Psi_j = U_j U_j^T / n \), and

\[
x_{j\ell} = \frac{\lambda_{1\ell}^2 n / (16\sigma_j^2) - \text{tr}(\Psi_j)}{\sqrt{2} \| \Psi_j \|_F}.
\]

We bound from the above the probability of \( A_{j\ell}^c \) using Lemma 10. Specifically, choose \( \nu = \nu_j = (\nu_{j,1}, \ldots, \nu_{j,n}), x = x_j \) and \( m(\nu) = \| \Psi_j \|_2 / \| \Psi_j \|_F = \| \nu_j \|_2 / \| \nu_j \|_F \) to obtain

\[
\mathbb{P}(A_{j\ell}^c) \leq 2 \exp\left\{ - \frac{x_{j\ell}^2}{2 \left( 1 + \sqrt{2x_{j\ell} \| \Psi_j \|_2 / \| \Psi_j \|_F} \right)} \right\}.
\]

Now we find the appropriate \( \lambda_{1\ell} \) such that the above probability approaches one as \( p \) and \( q \) increase with \( n \). Let

\[
\exp\left\{ - \frac{x_{j\ell}^2}{2 \left( 1 + \sqrt{2x_{j\ell} \| \Psi_j \|_2 / \| \Psi_j \|_F} \right)} \right\} \leq (pqm)^{-2},
\]

which implies \( x_{j\ell}^2 \geq 4 \log(pqm) (1 + \sqrt{2x_{j\ell} \| \Psi_j \|_2 / \| \Psi_j \|_F}) \). Equivalently, we need to have

\[
x_{j\ell} = \frac{\lambda_{1\ell}^2 n / (16\sigma_j^2) - \text{tr}(\Psi_j)}{\sqrt{2} \| \Psi_j \|_F} \geq 2\sqrt{2} \| \Psi_j \|_2 / \| \Psi_j \|_F \log(pqm) + \left[ 2 \left( 2 \| \Psi_j \|_2 / \| \Psi_j \|_F \log(pqm) \right)^2 + 4 \log(pqm) \right]^{1/2},
\]

or

\[
\lambda_{1\ell}^2 n / 16\sigma_j^2 \geq \text{tr}(\Psi_j) + 4 \| \Psi_j \|_2 \log(pqm) + \left[ 4 \left( 2 \| \Psi_j \|_2 \log(pqm) \right)^2 + 8 \| \Psi_j \|_F^2 \log(pqm) \right].
\]

Therefore, a sufficient condition for the above is (by noting \( (a + b)^{1/2} \leq a^{1/2} + b^{1/2}, \forall a, b \geq 0 \))

\[
\lambda_{1\ell}^2 n / 16\sigma_j^2 \geq \text{tr}(\Psi_j) + 8 \| \Psi_j \|_2 \log(pqm) + \left\{ 8 \| \Psi_j \|_F^2 \log(pqm) \right\}^{1/2}.
\] (7)
Therefore, when (7) holds, \( P(\mathcal{A}_q^\ell) \leq 2(pqm)^{-2} \). It suffices to find the probability of (7) when \( \lambda_r \geq 4c^*\sigma_r(14 \log(pqm)/n)^{1/2} \). By Lemma 7, when \( \{2 \log(pqm)m^3/n\}^{1/2} \leq 1 \), with probability at least \( 1 - \exp(-nm^{-3}) \) \( \geq 1 - (pqm)^{-2} \), the following inequality
\[
\text{tr}(\Psi_j) = \text{tr}\left( \frac{U_j^T U_j}{n} \right) = \text{tr}\left( \frac{\tilde{U}_j^T \tilde{U}_j}{n^2} - \frac{\tilde{U}_j^T \tilde{U}_j}{n^2} \right) \leq \text{tr}\left( \frac{\tilde{U}_j^T \tilde{U}_j}{n} \right) \leq m \frac{c^*}{m} = c^*
\]
holds, where the first inequality follows from the positive semidefiniteness of \( \tilde{U}_j^T \tilde{U}_j/n^2 \).

Similarly, \( \|\Psi_j\|_2 \leq c^*/m \) and \( \|\Psi_j\|_F \leq \{\|\Psi_j\|_2 \text{tr}(\Psi_j)\}^{1/2} \leq c^*/\sqrt{m} \). Therefore, when \( \lambda_r \geq 4c^*\sigma_r(14 \log(pqm)/n)^{1/2} \),
\[
\frac{\lambda_r^2 n/(16\sigma_r^2)}{\geq c^* + \frac{8c^* \log(pqm)}{m} + \left\{\frac{8(c^*)^2 \log(pqm)}{m}\right\}^{1/2}} \geq \text{tr}(\Psi_j) + 8\|\Psi_j\|_2 \log(pqm) + \left\{8\|\Psi_j\|_F^2 \log(pqm)\right\}^{1/2}
\]
holds with probability at least \( 1 - (pqm)^{-2} \). As a result, \( A_{\beta} \) happens with probability at least \( 1 - 3(pqm)^{-2} \) when \( \lambda_r \geq 4\sigma_r c^*(14 \log(pqm)/n)^{1/2} \). The proof is complete by taking the union bound argument. \( \square \)

**Lemma 13** (Error Bound for Approximation). Under the assumption of Lemma 4, the event
\[
\mathcal{D}_\ell = \left\{ \frac{1}{\sqrt{n}} \left\| U\tilde{\gamma}_\ell - \sum_{j=1}^{q} F_j \right\|_2 \leq 4rC_Lm^{-d} + 4r\left\{C_0^2 \log(pqm)/n\right\}^{1/2} \right\}
\]

happens with probability at least \( 1 - 2r(pqm)^{-2} \).

**Proof.** First, note that
\[
\frac{1}{n} \left\| U\tilde{\gamma}_\ell - \sum_{j=1}^{q} F_j \right\|_2^2 = \frac{1}{n} \sum_{i=1}^{n} \left\{ \sum_{j=1}^{q} f_{ij}(Z_{ij}) - \sum_{j=1}^{q} \sum_{k=1}^{m} \gamma_{jk} \psi_k(Z_{ij}) \right\}^2 \\
\leq \frac{1}{n} \sum_{i=1}^{n} \sum_{j \in J_\ell} \left\{ f_{ij}(Z_{ij}) - \sum_{k=1}^{m} \gamma_{jk} \psi_k(Z_{ij}) \right\}^2 \leq r \sum_{j \in J_\ell} \sup_{z \in [a,b]} \left| f_{ij}(z) - \tilde{f}_{ij}(z) \right|^2.
\]

Applying Lemma 1 with a union bound argument, with probability at least \( 1 - 2r(pqm)^{-2} \), we have
\[
\frac{1}{\sqrt{n}} \left\| U\tilde{\gamma}_\ell - \sum_{j=1}^{q} F_j \right\|_2 \leq 4rC_Lm^{-d} + 4r\left\{C_0^2 \log(pqm)/n\right\}^{1/2}.
\]

This completes the proof. \( \square \)

The next lemma resembles Lemma 11 but focus on classical restricted eigenvalue condition.

**Lemma 14.** Suppose \( \beta \) holds. Then with probability at least \( 1 - 2(pqm)^{-2} \)
\[
\min \left\{ \frac{\beta^T F^T F \beta}{n \left\| \beta \right\|_2^2} : \mathcal{L} \leq s, \beta \in \mathbb{R}^p \setminus \{0\}, \sum_{\ell \in \mathcal{L}} |\beta_\ell| \leq 3 \sum_{\ell \in \mathcal{L}} |\beta_\ell| \right\} \geq \frac{\kappa}{2}
\]
holds when \( 64sr^2C_0 \{\log(pqm)/n\}^{1/2} \leq \kappa/2 \) and \( \{\log(pqm)/n\} \leq 1/2 \).
Proof. Consider $\beta$ satisfying $\sum_{\ell \in L} |\beta_{\ell}| \leq 3 \sum_{\ell \in L} |\beta_{\ell}|$. Then,

\[
\frac{\beta^T F^TF \beta}{n} = \beta^T \Sigma_f \beta - \beta^T \Sigma_f \beta + \beta^T F^TF \beta \\
\geq \|\beta_{\ell}\|^2 \kappa - \beta^T \left( \Sigma_f - \frac{F^TF}{n} \right) \beta \\
= \|\beta_{\ell}\|^2 \kappa - \left( \sum_{\ell \in L} |\beta_{\ell}| + \sum_{\ell \in L} |\beta_{\ell}| \right)^2 \|\Sigma_f - \frac{F^TF}{n} \|_\infty \\
\geq \|\beta_{\ell}\|^2 \kappa - \left( 3 \sum_{\ell \in L} |\beta_{\ell}| + \sum_{\ell \in L} |\beta_{\ell}| \right)^2 \|\Sigma_f - \frac{F^TF}{n} \|_\infty \\
= \|\beta_{\ell}\|^2 \kappa - 16 \|\beta_{\ell}\|^2 \|\Sigma_f - \frac{F^TF}{n} \|_\infty \geq \|\beta_{\ell}\|^2 \kappa - 16 \|\beta_{\ell}\|^2 \|\Sigma_f - \frac{F^TF}{n} \|_\infty.
\]

We first bound $\|\Sigma_f - F^TF/n\|_\infty$:

\[
\left\| \Sigma_f - \frac{F^TF}{n} \right\|_\infty = \max_{\ell,\ell'} \mathbb{E}\left[ \left\{ \sum_{j=1}^q f_{\ell,j}(Z_j) \right\} \left\{ \sum_{j=1}^q f_{\ell',j}(Z_j) \right\} \right] - \sum_{i=1}^n \frac{1}{n^2} \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \left\{ \sum_{j=1}^q f_{\ell',j}(Z_{ij}) \right\}.
\]

As there are at most $r$ nonzero summands in $\sum_{j=1}^q f_{\ell,j}(z)$ for every $\ell \in \{1, \ldots, p\}$, we have

\[
\left\| \sum_{j=1}^q f_{\ell,j}(z) \right\|_\infty \leq r C_0, \; \forall \ell \in \{1, \ldots, p\},
\]

which implies

\[
\left\| \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \right\|_\infty \leq r^2 C_0^2.
\]

Now applying Lemma 8 with $b = r^2 C_0^2$ and $\delta = 4 r^2 C_0^2 (\log(pqm)/n)^{1/2}$, with probability at least $1 - 2 \exp \left[ -8 r^2 C_0^4 \log(pqm) / \{r^4 C_0^4 + \frac{1}{4} r^4 C_0^4 (\log(pqm)/n)^{1/2} \} \right]$, we have

\[
\mathbb{E}\left[ \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \right] - \sum_{i=1}^n \frac{1}{n^2} \left\{ \sum_{j=1}^q f_{\ell,j}(Z_{ij}) \right\} \left\{ \sum_{j=1}^q f_{\ell',j}(Z_{ij}) \right\} \leq 4 r^2 C_0^2 \left\{ \log(pqm) / n \right\}^{1/2}.
\]

When $\{\log(pqm)/n\}^{1/2} \leq 1/2$, we have

\[
1 - 2 \exp \left[ - \frac{8 r^4 C_0^4 \log(pqm)}{\{r^4 C_0^4 + \frac{1}{4} r^4 C_0^4 (\log(pqm)/n)^{1/2} \}} \right] \geq 1 - 2 (pqm)^{-4}
\]

and by taking the union bound we get

\[
\left\| \Sigma_f - \frac{F^TF}{n} \right\|_\infty \leq 4 r^2 C_0^2 \left\{ \log(pqm) / n \right\}^{1/2},
\]

22
which holds with probability at least $1 - 2p^2(pqm)^{-2}$. It follows that

$$\frac{\beta^T F^T F \beta}{n} \geq \|\beta_{E}\|^2/2 \kappa - 64s\|\beta_{E}\|^2 \epsilon^{-2} C_0^2 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2}$$

holds with probability at least $1 - 2p^2(pqm)^{-2}$. When $64s\epsilon^{-2} C_0^2 \{\log(pqm)/n\}^{1/2} \leq \kappa/2$, we have $\beta^T F^T F \beta/n \geq \kappa \|\beta_{L}\|^2/2$ holds with probability at least $1 - 2(pqm)^{-2}$. This concludes the lemma. \qed

**A.2 Proof of Results in Section 2**

**A.2.1 Proof of Lemma 1**

*Proof.* By the assumption $E\{f_{j\ell}(z_{ij})\} = 0$ and Lemma 4, we know

$$\sup_{z \in [0,1]} |f_{j\ell}(z) - \tilde{f}_{n_{j\ell}}(z)| \leq \sup_{z \in [0,1]} |f_{j\ell}(z) - \tilde{f}_{n_{j\ell}}(z)| + \left| \frac{1}{n} \sum_{k=1}^{n} \gamma_{j\ell} f_{k}(Z_{ij}) - \frac{1}{n} \sum_{i=1}^{n} f_{j\ell}(Z_{ij}) \right|
+ \left| \frac{1}{n} \sum_{i=1}^{n} f_{j\ell}(Z_{ij}) - \mathbb{E}(f_{j\ell}(Z_{ij})) \right|
\leq C_L m^{-d} + \frac{1}{n} \sum_{i=1}^{n} |\tilde{f}_{n_{j\ell}}(Z_{ij}) - f_{j\ell}(Z_{ij})| + \left| \frac{1}{n} \sum_{i=1}^{n} f_{j\ell}(Z_{ij}) - \mathbb{E}(f_{j\ell}(Z_{ij})) \right|
\leq 2C_L m^{-d} + \left| \frac{1}{n} \sum_{i=1}^{n} f_{j\ell}(Z_{ij}) - \mathbb{E}(f_{j\ell}) \right|,$$

where the first inequality is due to triangle inequality and second to the last inequality is due to Lemma 4. Finally, noting that $|f(Z_{ij})| \leq C_0$ and applying Lemma 3 with $t = \{4C_0^2 \log(pqm)/n\}^{1/2}$, we have that

$$\left| \frac{1}{n} \sum_{i=1}^{n} f_{j\ell}(Z_{ij}) - \mathbb{E}(f_{j\ell}) \right| \leq \{4C_0^2 \log(pqm)/n\}^{1/2}$$

holds with probability at least $1 - 2(pqm)^{-2}$. This completes the proof. \qed

**A.3 Proof of Results in Section 3**

**A.3.1 Proof of Theorem 1**

Consider the $\ell$th optimization problem in (3). By the optimality of $\hat{\gamma}_{\ell}$ in (3), we have $\forall \gamma_{\ell} \in \mathbb{R}^m$,

$$\frac{1}{n} \|U\hat{\gamma}_{\ell} - X_{\ell}\|^2 + 2\lambda_{\ell} \sum_{j=1}^{q} \|\hat{\gamma}_{j\ell}\|_{2} \leq \frac{1}{n} \|U\gamma_{\ell} - X_{\ell}\|^2 + 2\lambda_{\ell} \sum_{j=1}^{q} \|\gamma_{j\ell}\|_{2}.$$

23
Recall that \( \sum_{j=1}^{q} F_{j\ell} + \varepsilon_{\ell} = X_{\ell} \). Therefore,

\[
\frac{1}{n} \left\| U\tilde{\gamma}_{\ell} - \sum_{j=1}^{q} F_{j\ell} + U\tilde{\gamma}_{\ell} - U\tilde{\gamma}_{\ell} + \varepsilon_{\ell} \right\|_2^2 + 2\lambda_{\ell} \sum_{j=1}^{q} \| \tilde{\gamma}_{j\ell} \|_2
\]

Thus, we obtain

\[
\frac{1}{n} \left\| U\tilde{\gamma}_{\ell} - \sum_{j=1}^{q} F_{j\ell} + U\tilde{\gamma}_{\ell} - U\tilde{\gamma}_{\ell} + \varepsilon_{\ell} \right\|_2^2 + 2\lambda_{\ell} \sum_{j=1}^{q} \| \tilde{\gamma}_{j\ell} \|_2
\]

which implies that

\[
\frac{1}{n} \left\| U\tilde{\gamma}_{\ell} - \sum_{j=1}^{q} F_{j\ell} + U\tilde{\gamma}_{\ell} - U\tilde{\gamma}_{\ell} + \varepsilon_{\ell} \right\|_2^2 + 2\lambda_{\ell} \sum_{j=1}^{q} \| \tilde{\gamma}_{j\ell} \|_2
\]
where the last inequality holds due to the Cauchy–Schwarz inequality. By Lemma 12 and the choice of \( \lambda \), we have

\[
\frac{1}{n} \| U \hat{\gamma}_\ell - U \bar{\gamma}_\ell \|_2^2 + 2 \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} \|_2 \\
\leq \frac{1}{n} \| U \gamma_\ell - U \bar{\gamma}_\ell \|_2^2 + \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ \frac{q}{n^{1/2}} \| U \gamma_\ell - \sum_{j=1}^q F_{j\ell} \|_2 \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ 2 \lambda \sum_{j=1}^q \| \gamma_{j\ell} \|_2,
\]

with probability at least \( 1 - 3q(pqm)^{-2} \). Then by Lemma 7, we have

\[
\frac{1}{n} \| U \hat{\gamma}_\ell - U \bar{\gamma}_\ell \|_2^2 + 2 \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} \|_2 \\
\leq \frac{1}{n} \| U \gamma_\ell - U \bar{\gamma}_\ell \|_2^2 + \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ \sum_{j=1}^q \left( \frac{c^*}{n^2} \right) \frac{1}{2} \| U \gamma_\ell - \sum_{j=1}^q F_{j\ell} \|_2 \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ 2 \lambda \sum_{j=1}^q \| \gamma_{j\ell} \|_2,
\]

which holds with probability at least \( 1 - 4q(pqm)^{-2} \) (taking the union bound here) when \( 1 - \exp(-nm^{-3}) \geq 1 - (pqm)^{-2} \). Then by Lemma 13, we have

\[
\frac{1}{n} \| U \hat{\gamma}_\ell - U \bar{\gamma}_\ell \|_2^2 + 2 \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} \|_2 \\
\leq \frac{1}{n} \| U \gamma_\ell - U \bar{\gamma}_\ell \|_2^2 + \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ 2 \lambda \sum_{j=1}^q \| \gamma_{j\ell} \|_2 \\
+ \left[ 8rC_L(c^*)^{1/2}m^{-1/2-\delta} + 8r \left( \frac{C_0^2 \log(pqm)}{nm} \right)^{1/2} \right] \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
\leq \frac{1}{n} \| U \gamma_\ell - U \bar{\gamma}_\ell \|_2^2 + \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
+ 2 \lambda \sum_{j=1}^q \| \gamma_{j\ell} \|_2,
\]

which holds with probability at least \( 1 - 6q(pqm)^{-2} \) since \( r \leq q \). Setting \( \gamma_\ell = \bar{\gamma}_\ell \), we have

\[
\frac{1}{n} \| U \hat{\gamma}_\ell - U \bar{\gamma}_\ell \|_2^2 + \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 \\
\leq 2 \lambda \sum_{j=1}^q \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2 + 2 \lambda \sum_{j=1}^q \| \gamma_{j\ell} \|_2 \\
\leq 4 \lambda \sum_{j\in J_\ell} \| \hat{\gamma}_{j\ell} - \gamma_{j\ell} \|_2.
\]
Therefore, we know \( \lambda \sum_{j=1}^{q} ||\tilde{\gamma}_{j\ell} - \hat{\gamma}_{j\ell}||_2 \leq 4\lambda \sum_{j \in \mathcal{J}_\ell} ||\hat{\gamma}_{j\ell} - \tilde{\gamma}_{j\ell}||_2 \), which implies that

\[
\sum_{j \in \mathcal{J}_\ell} ||\tilde{\gamma}_{j\ell} - \hat{\gamma}_{j\ell}||_2 \leq 3 \sum_{j \in \mathcal{J}_\ell} ||\hat{\gamma}_{j\ell} - \tilde{\gamma}_{j\ell}||_2
\]

holds with probability at least \( 1 - 6q(pqm)^{-2} \). Then, combine with Lemma 11 to obtain

\[
||\hat{\gamma}_{J\ell} - \tilde{\gamma}_{J\ell}||_2 \leq \frac{||U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell||_2}{n^{1/2}} \left( \frac{2m}{\rho} \right)^{1/2},
\]

which holds with probability at least \( 1 - 12(qm)(pqm)^{-2} \). We also know from inequality (8) that

\[
\frac{1}{n}||U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell||_2^2 \leq 4\lambda \sum_{j \in \mathcal{J}_\ell} ||\hat{\gamma}_{j\ell} - \tilde{\gamma}_{j\ell}||_2 \leq 4\lambda \sqrt{r} ||\hat{\gamma}_{J\ell} - \tilde{\gamma}_{J\ell}||_2,
\]

which holds with probability at least \( 1 - 6q(pqm)^{-2} \), where the second inequality follows from the Cauchy–Schwarz inequality. Then, it follows that

\[
\frac{||U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell||_2}{n^{1/2}} \leq 4\lambda r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2}
\]

holds with probability at least \( 1 - 18(qm)(pqm)^{-2} \). It holds with the same probability that

\[
\sum_{j=1}^{q} ||\hat{\gamma}_{j\ell} - \tilde{\gamma}_{j\ell}||_2 \leq 4 \sum_{j \in \mathcal{J}_\ell} ||\hat{\gamma}_{j\ell} - \tilde{\gamma}_{j\ell}||_2 \leq 4n^{1/2} ||\hat{\gamma}_{J\ell} - \tilde{\gamma}_{J\ell}||_2
\]

\[
\leq 4r^{1/2} \frac{||U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell||_2}{\sqrt{n}} \left( \frac{2m}{\rho} \right)^{1/2} \leq 32\lambda \frac{m}{\rho}.
\]

Now we apply Lemma 13 to obtain

\[
\left\| \sum_{j=1}^{q} F_{j\ell} - U\hat{\gamma}_\ell \right\|_2 = \left\| \sum_{j=1}^{q} F_{j\ell} - U\hat{\gamma}_\ell + U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell \right\|_2
\]

\[
\leq \left\| \sum_{j=1}^{q} F_{j\ell} - U\hat{\gamma}_\ell \right\|_2 + ||U\hat{\gamma}_\ell - U\tilde{\gamma}_\ell||_2
\]

\[
\leq 4rn^{1/2}C_0 \rho^{-d} + 4rn^{1/2}C_0 \log(pqm)/n^{1/2} + 4\lambda \left( \frac{2m}{\rho} \right)^{1/2}
\]

\[
\leq 5\lambda \rho \left( \frac{2m}{\rho} \right)^{1/2},
\]

which holds with probability at least \( 1 - 20(qm)(pqm)^{-2} \), where the last inequality follows from the definition of \( \lambda \). The proof is complete by taking the union bound over all \( \ell \).

**A.3.2 Proof of Theorem 2**

**Lemma 15.** Suppose Assumptions 1–4 hold. If the regularization parameters satisfy

\[
560C_0 \lambda_{\max} \left( \frac{2m}{\rho} \right)^{1/2} \leq \frac{\kappa^2}{4r^3},
\]

(9)
then with probability at least $1 - 62(pqm)^{-1}$, the matrix $\hat{X} = U\hat{\Psi}$ satisfies
\[
\min \left\{ \frac{\|\hat{X}^\top \beta\|_{\infty}}{\sqrt{n} \|\beta\|_2} : \|L\|_1 \leq s, \beta \in \mathbb{R}^p \setminus \{0\}, \|\beta_{L^c}\|_1 \leq 3\|\delta_{L^c}\|_1 \right\} \geq \frac{\kappa}{2}
\]
when $n$ is sufficiently large.

**Proof.** For any subset $L \subset \{1, \ldots, p\}$ with $|L| \leq s$ and any $\delta \in \mathbb{R}^p$ such that $\delta \neq 0$ and $\|\delta_{L^c}\|_1 \leq 3\|\delta_{L}\|_1$, we have
\[
\frac{\delta^\top (F^\top F - \hat{X}^\top \hat{X}) \delta}{n\|\delta\|_2^2} \leq \frac{\|\delta\|_2^2 \max_{1 \leq \ell, \ell' \leq p} \left| \left( \sum_{j=1}^q F_{j\ell'} \right)^\top \left( \sum_{j=1}^q F_{j\ell} \right) - \hat{X}_{\ell'}^\top \hat{X}_{\ell} \right|}{n\|\delta\|_2^2}.
\]
Since $\|\delta_{L^c}\|_1 \leq 3\|\delta_{L}\|_1$, we have $\|\delta\|_2 = (\|\delta_{L}\|_1 + \|\delta_{L^c}\|_1)^2 \leq 16\|\delta_{L}\|_2 \leq 16\|\delta\|_2$, which implies that
\[
\frac{\delta^\top (F^\top F - \hat{X}^\top \hat{X}) \delta}{n\|\delta\|_2^2} \leq \frac{16s \max_{1 \leq \ell, \ell' \leq p} \left| \left( \sum_{j=1}^q F_{j\ell'} \right)^\top \left( \sum_{j=1}^q F_{j\ell} \right) - \hat{X}_{\ell'}^\top \hat{X}_{\ell} \right|}{n}.
\]
(10)
To bound the entrywise maximum, we write
\[
\left| \left( \sum_{j=1}^q F_{j\ell} \right)^\top \left( \sum_{j=1}^q F_{j\ell'} \right) - \hat{X}_{\ell'}^\top \hat{X}_{\ell} \right| = \left| \left( \tilde{X}_{\ell} - \sum_{j=1}^q F_{j\ell} \right)^\top \left( \tilde{X}_{\ell'} - \sum_{j=1}^q F_{j\ell'} \right) + \left( \hat{X}_{\ell} - \sum_{j=1}^q F_{j\ell} \right)^\top \left( \sum_{j=1}^q F_{j\ell} \right) + \sum_{j=1}^q F_{j\ell}^\top \left( \hat{X}_{\ell'} - \sum_{j=1}^q F_{j\ell'} \right) \right| = T_1 + T_2 + T_3.
\]
For $T_1$, by the Cauchy–Schwarz inequality and Theorem 1, we have
\[
T_1 \leq \|\tilde{X}_{\ell} - \sum_{j=1}^q F_{j\ell}\|_2 \cdot \left\| \sum_{j=1}^q F_{j\ell'} \right\|_2 \leq 25n\lambda_{\max}^2 \frac{2m}{\rho},
\]
which holds with probability at least $1 - 20(pqm)^{-1}$. For $T_2$, note that $\left\| \sum_{j=1}^q F_{j\ell} \right\|_2 \leq C_0 n^{1/2} r$, $\forall \ell \in \{1, \ldots, p\}$ due to the sparsity assumption. Then, we have
\[
T_2 \leq \left\| U_{\ell}^\top \tilde{X}_{\ell} - \sum_{j=1}^q F_{j\ell} \right\|_2 \cdot \left\| \sum_{j=1}^q F_{j\ell'} \right\|_2 \leq 5n\lambda_{\max} \left( \frac{2mr}{\rho} \right)^{1/2} rC_0
\]
which holds with probability at least $1 - 20(pqm)^{-1}$. Similarly, it holds with the same probability that
\[
T_3 \leq 5n\lambda_{\max} \left( \frac{2mr}{\rho} \right)^{1/2} rC_0.
\]

Therefore, we have
\[
\max_{1 \leq \ell, r \leq p} \left| \left( \sum_{j=1}^{q} F_{\ell r} \right)^T \left( \sum_{j=1}^{q} F_{\ell r} \right) - X_\ell^T \hat{X}_\ell \right| \leq 35n\lambda_{\max}rC_f \left( \frac{2m}{\rho} \right)^{1/2},
\]
which holds with probability at least 1 − 60(pqm)^{-1} when \( \lambda_{\max}(2m/\rho)^{1/2} \leq r^{1/2}C_0 \). We know from Lemma 14 that
\[
\min \left\{ \frac{\|f_{\beta}\|}{\sqrt{n}\|\beta_L\|} : |L| \leq s, \beta \in \mathbb{R}^p \setminus \{0\}, \|\beta_L\|_1 \leq 3\|\beta_L\|_1 \right\} \geq \frac{\sqrt{2}\kappa}{2}
\]
holds with probability at least 1 − 2(pqm)^{-2}. It follows from (9) and (10) that
\[
\frac{\delta^2(F^T F - \hat{X}^T \hat{X})\delta}{n\|\delta_L\|^2} \leq 560\lambda_{\max}C_0\kappa \left( \frac{2m}{\rho} \right)^{1/2} \leq \frac{\kappa^2}{4}
\]
holds with probability at least 1 − 60(pqm)^{-1}. Therefore, with probability at least 1 − 62(pqm)^{-1}, we get
\[
\frac{\beta^T(\hat{X}^T \hat{X})\beta}{n\|\beta_L\|^2} \geq \frac{\kappa^2}{4}
\]
This completes the proof. \( \square \)

**Lemma 16.** Under Assumptions 1–4, if the regularization parameters \( \lambda_\ell \)'s are chosen as in Theorem 1 and
\[
\mu = 2\lambda_{\max}r \left( \frac{2m}{\rho} \right)^{1/2} \left( 7\sigma_0 + 8\sqrt{5}B \max_\ell \sigma_\ell + 30B \right),
\]
then with probability at least 1 − 86(pqm)^{-1}, the regularized estimator \( \hat{\beta} \) of (4) satisfies
\[
\frac{1}{2n} \|Y - \hat{X}\hat{\beta}\|^2 + \frac{\mu}{2} \|\hat{\beta} - \beta\|_1 \leq 2\mu\|\beta_L - \beta_L\|_1.
\]

**Proof.** By the optimality of \( \hat{\beta} \), we have
\[
\frac{1}{2n} \|Y - \hat{X}\hat{\beta}\|^2 + \mu\|\hat{\beta}\|_1 \leq \frac{1}{2n} \|Y - \hat{X}\beta\|^2 + \mu\|\beta\|_1.
\]
Substituting \( Y = X\beta + \eta \), we have
\[
\|Y - \hat{X}\hat{\beta}\|^2 = \|\eta - (\hat{X}\hat{\beta} - X\beta)\|^2
\]
\[
= \|\eta\|^2 + \|\hat{X}\hat{\beta} - X\beta\|^2 - 2\eta^T(\hat{X}\hat{\beta} - X\beta)
\]
\[
= \|\eta\|^2 + \|\hat{X}\hat{\beta} - X\beta\|^2 + \|\hat{X}\beta - X\beta\|^2 - 2\eta^T(\hat{X}\beta - X\beta)
\]
\[
= \|\eta\|^2 + \|\hat{X}(\hat{\beta} - \beta)\|^2 + \|(-X\beta + \hat{X}\beta)\|^2 - 2\eta^T(\hat{X}\beta - X\beta)
\]
\[
+ 2\beta^T(-X + \hat{X})\hat{X}(\hat{\beta} - \beta)
\]
and
\[
\|Y - \hat{X}\beta\|^2 = \|\eta - (\hat{X} - X)\beta\|^2 = \|\eta\|^2 + \|(-X + \hat{X})\beta\|^2 - 2\eta^T(\hat{X} - X)\beta.
\]

28
It then follows that
\[
\frac{1}{2n} \| \hat{X}(\hat{\beta} - \beta) \|_2^2 \leq \mu \| \beta \|_1 - \mu \| \hat{\beta} \|_1 + \frac{1}{n} \eta^T \hat{X}(\hat{\beta} - \beta) - \frac{1}{n} \beta^T (\hat{X} - X)^T \hat{X}(\hat{\beta} - \beta)
\]
\[
\leq \mu \| \beta \|_1 - \mu \| \hat{\beta} \|_1 + \left\| \frac{1}{n} \hat{X}^T \eta - \frac{1}{n} \hat{X}^T (\hat{X} - X) \beta \right\|_\infty \| \hat{\beta} - \beta \|_1. \tag{11}
\]
Next, we find a probability bound for the following event
\[
\left\| \frac{1}{n} \hat{X}^T \eta - \frac{1}{n} \hat{X}^T (\hat{X} - X) \beta \right\|_\infty \leq \frac{\mu}{2}.
\]
Substituting \( \hat{X} = U \hat{\Gamma} \) and \( X = F + \varepsilon \), we write
\[
\frac{1}{n} \hat{X}^T \eta - \frac{1}{n} \hat{X}^T (\hat{X} - X) \beta = \frac{1}{n} (U \hat{\Gamma})^T \eta - \frac{1}{n} (U \hat{\Gamma})^T (U \hat{\Gamma} - X) \beta
\]
\[
= \frac{1}{n} \hat{\Gamma}^T U^T \eta - \frac{1}{n} \hat{\Gamma}^T U^T (U \hat{\Gamma} - F - \varepsilon) \beta
\]
\[
= \frac{1}{n} \left( \hat{\Gamma}^T U^T - F^T \right) \eta + \frac{1}{n} F^T \eta + \frac{1}{n} \left( \hat{\Gamma}^T U^T - F^T \right) \varepsilon \beta + \frac{1}{n} F^T \varepsilon \beta
\]
\[
- \frac{1}{n} \left( \hat{\Gamma}^T U^T - F^T \right)(U \hat{\Gamma} - F) \beta - \frac{1}{n} F^T (U \hat{\Gamma} - F) \beta
\]
\[
= T_1 + T_2 + T_3 + T_4 + T_5 + T_6.
\]
For \( T_1 \), it follows from Theorem 1 that
\[
\| T_1 \|_\infty \leq \frac{1}{n} \max_i \left\| \sum_{j=1}^q F_{ji} - U^T \gamma_i \right\|_2 \| \eta \|_2 \leq 5 \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} \| \eta \|_2 \quad \frac{n}{\| \eta \|_2^{1/2}}
\]
holds with probability at least \( 1 - 20(pqm)^{-1} \). For a Gaussian variable \( \eta_i \), \( \eta_i^2 \) is sub-exponential and follows the \( \sigma_0^2 \chi^2 \) distribution. Apply Lemma 9 with \( t = \{16 \log(pqm)/n\}^{1/2} \) to obtain
\[
\left| \frac{1}{\sigma_0^2 n} \| \eta \|_2^2 - 1 \right| \leq 4 \left( \frac{\log(pqm)}{n} \right)^{1/2},
\]
which holds with probability at least \( 1 - 2(pqm)^{-2} \). Therefore, we have
\[
\| T_1 \|_\infty \leq 5 \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} \left( \| \eta \|_2 \right)^{1/2}
\]
\[
\leq 5 \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} \left[ 4 \sigma_0^2 \left( \log(pqm)/n \right)^{1/2} + \sigma_0^2 \right]
\]
\[
\leq 5 \lambda_{\max} r^{1/2} \left( \frac{10m}{\rho} \right)^{1/2} \sigma_0,
\]
which holds with probability at least \( 1 - 22(pqm)^{-1} \) when \( \log(pqm)/n \leq 1 \). For \( T_2 \), we have
\[
\| T_2 \|_\infty = \frac{1}{n} \| f^T \eta \|_\infty \leq \frac{1}{n} \max_i \left\| \left( \sum_{j=1}^q F_{ji} \right)^T \eta \right\|_\infty.
\]
By the tail bound of a standard normal random variable $X$

$$P(|X| \geq t) \leq 2 \left( \frac{2}{\pi} \right)^{1/2} \frac{\exp(-t^2/2)}{t},$$

we have

$$P(\|T_2\|_\infty \geq t) \leq \mathbb{P}\left\{ \frac{1}{n} \max_{\ell} \left| \left( \sum_{j=1}^{q} F_{j\ell} \right)^T \eta \right| \geq t \right\}$$

$$\leq p \mathbb{P}\left( \frac{1}{n} \sum_{j=1}^{q} F_{j\ell}^T \eta \geq t \right) = p \mathbb{P}\left( \frac{1}{n} \sum_{j \in J_0} F_{j\ell}^T \eta \geq t \right)$$

$$\leq 2p \left( \frac{2}{\pi} \right)^{1/2} \exp \left[ \frac{-n^2 t^2}{2 \sigma_0^2 \sum_{i=1}^{n} \left\{ \sum_{j \in J_0} f_{j\ell}(Z_{ij}) \right\}^2} \right] \sigma_0 \left[ \sum_{i=1}^{n} \left\{ \sum_{j \in J_0} f_{j\ell}(Z_{ij}) \right\}^2 \right]^{1/2}$$

Note that $\sum_{i=1}^{n} \left\{ \sum_{j \in J_0} f_{j\ell}(Z_{ij}) \right\}^2 \leq r^2 C_0^2 n$. By setting $t = 2C_0 \left\{ r^2 \log(pqm) / n \right\}^{1/2} \sigma_0$, we obtain

$$P(\|T_2\|_\infty \geq 2C_0 \left\{ r^2 \log(pqm) / n \right\}^{1/2} \sigma_0) \leq p(pqm)^{-2}.$$ 

Therefore, we can bound $T_2$ as

$$\|T_2\|_\infty \leq 2C_0 \sigma_0 \left\{ \frac{r^2 \log(pqm)}{n} \right\}^{1/2},$$

which holds with probability at least $1 - p(pqm)^{-2}$. Now for $T_3$, we have

$$\|T_3\|_\infty \leq \|\beta\|_1 \frac{1}{n} \left\| (U\hat{\Gamma} - F)^T \epsilon \right\|_\infty \leq B \frac{1}{n} \max_{\ell, \ell'} \left\| U\hat{\gamma}_{\ell} - \sum_{j=1}^{q} F_{j\ell} \right\| \|\epsilon_{\ell'}\|_2.$$ 

It follows from Theorem 1 that

$$\max_{\ell} \left\| U\hat{\gamma}_{\ell} - \sum_{j=1}^{q} F_{j\ell} \right\|_2 \leq 5 \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} \sqrt{n},$$

which implies that

$$\|T_3\|_\infty \leq 5B \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} \max_{\ell, \ell'} \frac{\|\epsilon_{\ell'}\|_2}{\sqrt{n}}$$

holds with probability at least $1 - 20(pqm)^{-1}$. Now applying Lemma 9 again with $t = \{16 \log(pqm) / n\}^{1/2}$, we get

$$\left| \frac{\|\epsilon_{\ell'}\|_2^2}{n\sigma_{\ell'}^2} - 1 \right| \leq 4 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2}$$
with probability at least $1 - 2(pqm)^{-2}$, which implies
\[
\frac{\|\epsilon_{\ell}\|^2}{n^{1/2}} \leq \left[4\sigma_{\ell}^2 \left(\log(pqm)/n\right)^{1/2} + \sigma_{\ell}^2 \right] \leq \sqrt{5}\sigma_{\ell},
\]
with probability at least $1 - 2(pqm)^{-2}$ when $\log(pqm)/n \leq 1$. Therefore, we have
\[
\|T_3\|_{\infty} \leq 5\sqrt{5} \max_{\ell} \sigma_{\ell} B \lambda_{\max} r^{1/2} \left(\frac{2n}{\rho}\right)^{1/2} = 5B \max_{\ell} \sigma_{\ell} \lambda_{\max} \left(\frac{10r \rho}{m}\right)^{1/2},
\]
which holds with probability at least $1 - 22(pqm)^{-1}$. Similar to $T_2$, we can bound $T_3$ as
\[
\|T_3\|_{\infty} = \frac{1}{n} \|F^T \epsilon\|_{\infty} \leq \frac{\|\beta\|_1}{n} \|F^T \epsilon\|_{\infty} \leq \frac{B}{n} \max_{\ell, t, \ell'} \left(\sum_{j=1}^q F_{jt}\right)^\top \epsilon_{\ell'}.
\]
Therefore, we have
\[
\mathbb{P}(\|T_3\|_{\infty} \geq t) \leq p^2 \mathbb{P} \left\{ \frac{B}{n} \left(\sum_{j=1}^q F_{jt}\right)^\top \epsilon_{\ell'} \geq t \right\} = p^2 \mathbb{P} \left\{ \frac{B}{n} \left(\sum_{j=1}^q F_{jt}\right)^\top \epsilon_{\ell'} \geq t \right\} \leq 2p^2 \left(\frac{2}{n}\right)^{1/2} \exp \left[ -\frac{n^2 t^2}{2\sigma_{\ell}^2 B^2 \sum_{j=1}^q \left(\sum_{j=1}^q F_{jt}(Z_{ij})\right)^2} \right].
\]
Since $\sum_{i=1}^n \left(\sum_{j=1}^q F_{jt}(Z_{ij})\right)^2 \leq r^2 C_0^2 n$, by setting $t = \max_{t'} \sigma_{t'} BC_0 \{8r^2 \log(pqm)/n\}^{1/2}$, we obtain
\[
\|T_3\|_{\infty} \leq \max_{t'} \sigma_{t'} BC_0 \{8r^2 \log(pqm)/n\}^{1/2},
\]
which holds with probability at least $1 - p^2(pqm)^{-4}$. Now we bound $T_5$ as
\[
\|T_5\|_{\infty} \leq \frac{\|\beta\|_1}{n} \|\left(\hat{F}^T U^T - F^T\right) (\hat{U}^T - F)\|_{\infty}
\leq \frac{B}{n} \max_{t, t'} \left\| \sum_{j=1}^q F_{jt} - U_{\gamma_{t'}} \right\|_2 \left\| \sum_{j=1}^q F_{jt} - U_{\gamma_{t'}} \right\|_2
\leq \frac{B}{n} \max_{\ell, t, \ell'} \left\| \sum_{j=1}^q F_{jt} - U_{\gamma_{t'}} \right\|_2^2 \leq 25B \lambda_{\max}^2 \frac{2n}{\rho},
\]
which holds with probability at least $1 - 20(pqm)^{-1}$. Finally, we bound $T_6$ as
\[
\|T_6\|_{\infty} \leq \frac{\|\beta\|_1}{n} \|F^T (U \hat{U} - F)\|_{\infty} \leq \frac{B}{n} \max_{t, t'} \left\| \sum_{j=1}^q F_{jt} \right\|_2 \left\| \sum_{j=1}^q F_{jt} - U_{\gamma_{t'}} \right\|_2
\leq \frac{B}{n} (rn)^{1/2} C_0 \max_{t'} \left\| \sum_{j=1}^q F_{jt} \right\|_2 \leq 5Bn \lambda_{\max} \left(\frac{2m}{\rho}\right)^{1/2},
\]
31
which holds with probability at least $1 - 20(pqm)^{-1}$. Therefore, we have

\[
\frac{1}{n} \left\| \frac{1}{n} \hat{X} \tau \eta - \frac{1}{n} \hat{X} \tau (\hat{X} - X) \beta \right\|_\infty \\
\leq \|T_1\|_\infty + \|T_2\|_\infty + \|T_3\|_\infty + \|T_4\|_\infty + \|T_5\|_\infty + \|T_6\|_\infty \\
\leq 5\sigma_0 \lambda_{\max} \left( \frac{2rm}{\rho} \right)^{1/2} + 2C_0 \sigma_0 r \left\{ \log(pqm) \right\} \left( \frac{n}{m} \right)^{1/2} + 5B \max \sigma_{\ell} (r)^{1/2} \lambda_{\max} \left( \frac{10rm}{n} \right)^{1/2} \\
+ \max_{\ell} \sigma_{\ell} B C_0 r \left\{ \frac{8 \log(pqm)}{n} \right\} \left( \frac{2m}{\rho} \right)^{1/2} + 25B \lambda_{\max}^2 \frac{2m}{\rho} + 5Br \max \sigma_{\ell} \left( \frac{2m}{\rho} \right)^{1/2} \\
\leq 7\sigma_0 \lambda_{\max} \left( \frac{2rm}{\rho} \right)^{1/2} + 8B \max \sigma_{\ell} r \lambda_{\max} \left( \frac{10m}{n} \right)^{1/2} + 30B \lambda_{\max} \left( \frac{2m}{\rho} \right)^{1/2} \\
\leq \lambda_{\max} \left( \frac{2m}{\rho} \right)^{1/2} (7\sigma_0 + 8\sqrt{5B} \max \sigma_{\ell} + 30B),
\]

which holds with probability at least $1 - 86(pqm)^{-1}$ when $\lambda_{\max} (2m/\rho)^{1/2} \leq 1$, where we use the definition of $\lambda_{\max}$ in the third inequality. This, together with (11), implies

\[
\frac{1}{2n} \left\| \hat{X} (\hat{\beta} - \beta) \right\|_2^2 \leq \mu \left\| \beta \right\|_1 - \mu \left\| \hat{\beta} \right\|_1 + \frac{\mu}{2} \left\| \hat{\beta} - \beta \right\|_1.
\]

Adding $\mu \left\| \hat{\beta} - \beta \right\|_2^2$ to both sides yields

\[
\frac{1}{2n} \left\| \hat{X} (\hat{\beta} - \beta) \right\|_2^2 + \frac{\mu}{2} \left\| \hat{\beta} - \beta \right\|_1 \leq \mu \left( \left\| \beta \right\|_1 - \left\| \hat{\beta} \right\|_1 + \left\| \hat{\beta} - \beta \right\|_1 \right) \\
= \mu \left( \left\| \beta \right\|_1 + \left\| \hat{\beta} \right\|_1 + \left\| \hat{\beta} - \beta \right\|_1 - \left\| \hat{\beta} \right\|_1 + \left\| \hat{\beta} - \beta \right\|_1 \right) \\
= \mu \left( \left\| \beta \right\|_1 + \left\| \hat{\beta} \right\|_1 + \left\| \hat{\beta} - \beta \right\|_1 \right) \\
= \mu \left( \left\| \beta \right\|_1 + \left\| \hat{\beta} \right\|_1 + \left\| \hat{\beta} - \beta \right\|_1 \right) \leq 2\mu \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_1,
\]

where the last inequality follows from the triangle inequality. This completes the proof.

Now we are ready to prove our main results. We note from Lemma 16 that with probability at least $1 - 86(pqm)^{-1}$, we have

\[
\frac{1}{2n} \left\| \hat{X} (\hat{\beta} - \beta) \right\|_2^2 \leq 2\mu \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_1 \leq 2\mu s^{1/2} \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_2 \\
\tag{12}
\]

and

\[
\frac{\mu}{2} \left\| \hat{\beta} - \beta \right\|_1 \leq 2\mu \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_1.
\]

By Lemma 15, with probability at least $1 - 148(pqm)^{-1}$, we have

\[
\left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_2 \leq \frac{2}{n^{1/2}} \left\| \hat{X} (\hat{\beta} - \beta) \right\|_2. \\
\tag{13}
\]

Combining (12) and (13), we obtain

\[
\left\| \hat{X} (\hat{\beta} - \beta) \right\|_2^2 \leq \frac{64}{\kappa^2} n s \mu^2
\]

and

\[
\left\| \hat{\beta} - \beta \right\|_1 \leq 4 \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_1 \leq 4s^{1/2} \left\| \hat{\beta} \right\|_2 - \left\| \beta \right\|_2 \leq \frac{64}{\kappa^2} s \mu,
\]

which hold with probability at least $1 - 234(pqm)^{-1}$.
A.4 Proof of Results in Section 4

A.4.1 Proof of Lemma 2

Proof. Note that
\[ \tilde{\beta} = \hat{\beta} + \hat{\Omega}\hat{D}^\top(Y - X\hat{\beta})/n \]
\[ = \hat{\beta} + \hat{\Omega}\hat{D}^\top(X(\beta - \tilde{\beta}) + \eta)/n \]
\[ = \hat{\beta} + \hat{\Omega}\hat{D}^\top(D(\beta - \tilde{\beta}) + (X - \tilde{D})(\beta - \tilde{\beta}) + \eta)/n \]
\[ = \beta + \hat{\Omega}\hat{D}^\top\eta/n + \hat{\Omega}\hat{D}^\top(X - \tilde{D})(\beta - \tilde{\beta})/n + (\hat{\Omega}\hat{\Sigma}_d - I)(\beta - \tilde{\beta}). \]

Now decompose the second term on the rightmost-hand side of the above display as
\[ \hat{\Omega}\hat{D}^\top\eta/n = \hat{\Omega}D^\top\eta/n + \hat{\Omega}(\hat{D} - D)^\top\eta/n \]
\[ = \Omega D^\top\eta/n + (\Omega - \hat{\Omega})D^\top\eta/n + \hat{\Omega}(\hat{D} - D)^\top\eta/n, \]
which completes the proof.

A.4.2 Proof of Theorem 3

Proof. In this proof, we will temporarily assume \( \|R_k\|_\infty = o_p(1) \), \( k = 1, 2, 3, 4 \), which will be elaborated in the next subsection. First, we show \( \omega_\ell \) is bounded away from zero for large \( n \), that is, \( \omega_\ell \geq c \) for some constant \( c > 0 \). This follows immediately since \( \Omega_{\ell\ell} \) is lower bounded by a constant. Define
\[ T_{\ell,n} = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (\theta_\ell^T \Gamma^T \tilde{U}_i^T) \frac{\eta_i}{\omega_\ell}, \]
where \( \tilde{U}_i \) is the \( i \)th row of \( \tilde{U} \). Then, we have
\[ \left| T_{\ell,n} - n^{1/2} \frac{\hat{\beta}_\ell - \beta_\ell}{\omega_\ell} \right| \leq \left| \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \theta_\ell^T \Gamma^T \tilde{U}_i^T \frac{\eta_i}{\omega_\ell} - \theta_\ell^T D^\top \eta/n \frac{1}{\sqrt{n} \omega_\ell} - \frac{4}{\min_{\ell} \omega_\ell} R_{\ell} \right| \]
\[ \leq \left| \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \theta_\ell^T \Gamma^T \tilde{U}_i^T \frac{\eta_i}{\omega_\ell} - \theta_\ell^T D^\top \eta/n \frac{1}{\sqrt{n} \omega_\ell} \right| \leq \sum_{i=1}^{n} \frac{\|R_i\|_\infty}{\min_{\ell} \omega_\ell}. \]

As noted above, we will control the remainder terms \( \|R_k\|_\infty \) in the next subsection and for now we assume they are all \( o_p(1) \). Now we have
\[ \left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_\ell^T \Gamma^T \tilde{U}_i^T \frac{\eta_i}{\omega_\ell} - \frac{\theta_\ell^T D^\top \eta}{n^{1/2} \omega_\ell} \right| = \frac{1}{n^{1/2} \omega_\ell} \left| \frac{1}{n} \theta_\ell^T \Gamma^T \tilde{U}^T 1^\top \eta \right| \leq \frac{1}{n^{1/2} \omega_\ell} \left| \theta_\ell^T \Gamma^T \tilde{U}^T 1^\top \eta \right| \leq \frac{1}{n^{1/2} \omega_\ell} \left| \theta_\ell^T \Gamma^T \tilde{U}^T 1^\top \eta \right| \leq \frac{1}{n^{1/2} \omega_\ell} \left| \theta_\ell^T F^\top 1^\top \eta \right| \leq \frac{1}{n^{1/2} \omega_\ell} \left| \theta_\ell^T (\Gamma^T \tilde{U}^T - F^\top) 1^\top \eta \right| + \frac{1}{n^{1/2} \omega_\ell} \left| \theta_\ell^T F^\top 1^\top \eta \right|, \]
Similarly, by Lemma 3, we have

$$\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \frac{\eta_{i}}{\omega_{t}} - \frac{\theta_{t}^{\mathbf{T}} D^{\top} \eta}{n^{1/2} \omega_{t}} \right|$$

where the first equality follows from the fact

$$\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \eta_{i} - \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \eta_{i} + \frac{1}{n} \theta_{t}^{\mathbf{T}} 11^{\top} \eta \right|$$

$$\leq \frac{1}{n^{1/2} \omega_{t}} \left| \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \eta_{i} \right|$$

Apply the H"older's inequality to get

$$\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \frac{\eta_{i}}{\omega_{t}} - \frac{\theta_{t}^{\mathbf{T}} D^{\top} \eta}{n^{1/2} \omega_{t}} \right|$$

$$\leq \frac{1}{n^{1/2} \omega_{t}} \left( \left\| \theta_{t} \right\|_{1} \max_{\ell} \left\| \sum_{j=1}^{q} F_{\ell j} - \hat{U}_{i \ell} \gamma_{\ell} \right\|_{2} + \left\| \theta_{t} \right\|_{1} \left\| F^{\top} \right\|_{\infty} \right) \frac{1}{n} \left| \sum_{i=1}^{n} \eta_{i} \right|$$

$$\leq \left\{ m_{\Omega} \max_{\ell} \left\| \sum_{j=1}^{q} F_{\ell j} - \hat{U}_{i \ell} \gamma_{\ell} \right\|_{2} + m_{\Omega} \max_{\ell} \left\| \sum_{j=1}^{q} \sum_{i=1}^{n} f_{\ell i}(Z_{ij}) \right\|_{/n^{1/2} \omega_{t}} \right\} \frac{1}{n} \left| \sum_{i=1}^{n} \eta_{i} \right|$$

$$\leq \left\{ m_{\Omega} \max_{j} \left\| \sum_{i=1}^{n} f_{j i}(Z_{ij}) \right\|_{/n^{1/2} \omega_{t}} \right\} \frac{1}{n} \left| \sum_{i=1}^{n} \eta_{i} \right|$$

It then follows from the Gaussian tail probability that

$$P \left( \left| \frac{1}{n^{1/2} \sigma_{0}} \sum_{i=1}^{n} \eta_{i} \right| \geq t \right) \leq 2 \left( \frac{2}{\pi} \right)^{1/2} \exp \left( -t^{2}/2 \right)$$

Setting $t = 2(\log(n))^{1/2}$, we obtain with probability at least $1 - n^{-1}$

$$\left| \frac{1}{n} \sum_{i=1}^{n} \eta_{i} \right| \leq \sigma_{0} \left\{ \log(n) \right\}^{1/2}.$$

Similarly, by Lemma 3, we have

$$\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} f_{j i}(Z_{ij}) \right| \leq \left\{ 4C_{0} \log(pqm)/n \right\}^{1/2}$$

with probability at least $1 - 2(pqm)^{-2}$. By the union bound argument, we have

$$\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_{t}^{\mathbf{T}} \hat{U}_{i}^{\top} \frac{\eta_{i}}{\omega_{t}} - \frac{\theta_{t}^{\mathbf{T}} D^{\top} \eta}{n^{1/2} \omega_{t}} \right| \leq \sigma_{0} \left\{ \log(n) \right\}^{1/2} \frac{m_{\Omega}}{\omega_{t}} \left[ C_{L} m^{-d} + 2C_{0} \left\{ \log(pqm)/n \right\}^{1/2} \right]$$

34
with probability at least $1 - 2(pqm)^{-1} - n^{-1}$. Since $\omega_t$ is lower bounded by a constant when $n$ is large, we conclude

\[
\left| \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_i^T \Gamma^T \hat{U}_i^T \eta - \frac{\theta_i^T D^T \eta}{n^{1/2} \omega_t} \right| = o_p(1).
\]

It follows that

\[
\left| T_{t,n} - n^{1/2} \frac{\beta_t - \beta_t}{\omega_t} \right| = o_p(1).
\]

Therefore, $T_{t,n}$ and $\sqrt{n}(\beta_t - \beta_t)/\omega_t$ share the same weak limit. Now we show $T_{t,n}$ converges in distribution to the standard normal. Note that

\[
T_{t,n} = \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_i^T \Gamma^T \hat{U}_i^T \eta / \omega_t
\]

\[
= \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_i^T \Gamma^T \hat{U}_i^T \eta / \omega_t \left\{ \frac{1}{n} \sum_{i=1}^{n} \theta_i^T \Gamma^T \mathbb{E}(\hat{U}_i^T \hat{U}_i) \Gamma \theta_i \right\}^{1/2} \sigma_0 / \sigma_0 \left\{ \theta_i^T \mathbb{E}(\Gamma^T \mathbb{U}^T \mathbb{U}^T / n) \theta_i \right\}^{1/2}
\]

It follows that

\[
P \left[ \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left\{ \frac{1}{n} \sum_{i=1}^{n} \theta_i^T \Gamma^T \mathbb{E}(\hat{U}_i^T \hat{U}_i) \Gamma \theta_i \right\}^{1/2} \sigma_0 \leq t \right] = \mathbb{E} \left[ \text{P} \left( \frac{1}{n^{1/2}} \sum_{i=1}^{n} \theta_i^T \Gamma^T \hat{U}_i^T \eta / \omega_t \left\{ \frac{1}{n} \sum_{i=1}^{n} \theta_i^T \Gamma^T \mathbb{E}(\hat{U}_i^T \hat{U}_i) \Gamma \theta_i \right\}^{1/2} \sigma_0 \leq t \right) \right] = \mathbb{E} \left\{ \Phi(t) \right\} = \Phi(t)
\]

for all $t \in \mathbb{R}$, where $\Phi(t)$ denotes the CDF of the standard normal distribution. Finally, we note that

\[
\left\{ \frac{1}{n} \sum_{i=1}^{n} \theta_i^T \Gamma^T \mathbb{E}(\hat{U}_i^T \hat{U}_i) \Gamma \theta_i \right\}^{1/2} \sigma_0 = \left( \frac{n}{n-1} \right)^{1/2},
\]

where we use the fact that $\mathbb{E}(\hat{U}^T \hat{U} / n) = \frac{n-1}{n} \mathbb{E}(\mathbb{U}^T \mathbb{U} / n)$. Then, by the triangular inequality, we have

\[
\left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{\Gamma^T \mathbb{U}^T \mathbb{U}^T}{n} \right) \right\|_{\infty}
\]

\[
= \left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{n-1}{n} \Gamma^T \mathbb{U}^T \mathbb{U}^T \right) \right\|_{\infty}
\]

\[
\leq \left\| \mathbb{E} \left( \frac{n-1}{n} \frac{F^T F}{n} - \frac{n-1}{n} \Gamma^T \mathbb{U}^T \mathbb{U}^T \right) \right\|_{\infty} + \left\| \frac{1}{n} \mathbb{E} \left( \frac{F^T F}{n} \right) \right\|_{\infty}
\]

\[
= \frac{n-1}{n} \left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{F^T \mathbb{U}^T}{n} + \frac{F^T \mathbb{U}^T}{n} - \frac{\Gamma^T \mathbb{U}^T \mathbb{U}^T}{n} \right) \right\|_{\infty} + \left\| \frac{1}{n} \mathbb{E} \left( \frac{F^T F}{n} \right) \right\|_{\infty}
\]

\[
\leq \frac{n-1}{n} \left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{F^T \mathbb{U}^T}{n} \right) \right\|_{\infty} + n-1 \left\| \mathbb{E} \left( \frac{F^T \mathbb{U}^T}{n} - \frac{\Gamma^T \mathbb{U}^T \mathbb{U}^T}{n} \right) \right\|_{\infty}
\]

\[
+ \left\| \frac{1}{n} \mathbb{E} \left( \frac{F^T F}{n} \right) \right\|_{\infty}.
\]

35
It then follows from the triangular and Jensen’s inequalities that

\[
\left\| \mathbb{E}\left( \frac{F^t F}{n} - \frac{\Gamma^t U^t U \Gamma}{n} \right) \right\|_{\infty} \\
\leq \frac{n - 1}{n} \max_{\ell, \ell'} \frac{1}{\| F_{j, \ell} \|_2} \left\| \left( \sum_{j=1}^q F_{j, \ell} - \tilde{U}_{j, \ell} \right) \right\|_2 \\
+ \frac{n - 1}{n} \max_{\ell, \ell'} \frac{1}{\| F_{j, \ell} \|_2} \left\| \left( \sum_{j=1}^q F_{j, \ell'} - \tilde{U}_{j, \ell'} \right) \right\|_2 \\
+ \frac{1}{n} \max_{\ell, \ell'} \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2
\]

Now we apply the Cauchy–Schwarz inequality to get

\[
\left\| \mathbb{E}\left( \frac{F^t F}{n} - \frac{\Gamma^t U^t U \Gamma}{n} \right) \right\|_{\infty} \\
\leq \frac{n - 1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
+ \frac{n - 1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
+ \frac{1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \cdot \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
\leq \frac{n - 1}{n} r C_0 \mathbb{E} \max_{\ell} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \right\} \\
+ \frac{n - 1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
+ \frac{1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
\leq \frac{n - 1}{n} r C_0 \mathbb{E} \max_{\ell} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \right\} \\
+ \frac{n - 1}{n} \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} + r C_0 \mathbb{E} \max_{\ell, \ell'} \left\{ \left\| \sum_{j=1}^q F_{j, \ell} \right\|_2 \left\| \sum_{j=1}^q F_{j, \ell'} \right\|_2 \right\} \\
+ \frac{r^2 C_0^2}{n}.
\]

36
Finally, we obtain
\[
\left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{\Gamma^T U^T U}{n} \right) \right\|_\infty \\
\leq \frac{n-1}{n} r^2 C_0 \sup_{z \in [a, b]} \left| f_{j\ell}(z) - \sum_{k=1}^{m_n} \hat{\gamma}_{jk\ell} \phi_k(z) \right| + \frac{r^2 C_0^2}{n} \\
+ \frac{n-1}{n} \left\{ r \sup_{z \in [a, b]} \left| f_{j\ell}(z) - \sum_{k=1}^{m_n} \hat{\gamma}_{jk\ell} \phi_k(z) \right| + r C_0 \right\} \left\{ r \sup_{z \in [a, b]} \left| f_{j\ell}(z) - \sum_{k=1}^{m_n} \hat{\gamma}_{jk\ell} \phi_k(z) \right| \right\},
\]
where we apply the Cauchy–Schwarz and triangular inequalities. Now by Lemma 4, we have
\[
\left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{\Gamma^T U^T U}{n} \right) \right\|_\infty \leq \frac{n-1}{n} r^2 C_0 C_L m_n^{-d} + \frac{n-1}{n} \left( r C_L m_n^{-d} + r C_0 \right) r C_2^2 C_0^2 \\
\leq 3 \frac{n-1}{n} r^2 C_0 C_L m_n^{-d} + \frac{r^2 C_0^2}{n}.
\]
The above inequality holds when \( C_L m_n^{-d} \leq C_0 \). It then follows that
\[
\left\| \mathbb{E} \left( \frac{F^T F}{n} - \frac{\Gamma^T U^T U}{n} \right) \right\|_\infty \leq \frac{3}{n} m_0 \frac{n-1}{n} \left( r^2 C_0 C_L m_n^{-d} + \frac{r^2 C_0^2}{n} \right),
\]
from which we know
\[
\sigma_0 \left\{ \mathbb{E} \left( \frac{\Gamma^T U^T U}{n} \right) \theta_\ell \right\}^{1/2} \to \omega_\ell.
\]
Next, we show, for a consistent estimator \( \hat{\omega}_\ell \),
\[
n^{1/2} (\hat{\beta}_\ell - \beta_\ell) / \hat{\omega}_\ell \to \mathcal{N}(0, 1).
\]
Since \( \omega_\ell \) is lower bounded by a constant when \( n \) is large, for a consistent estimator \( \hat{\omega}_\ell \), we know \( \hat{\omega}_\ell = \Omega_p(1) \). Therefore, we have
\[
\left| \frac{\hat{\omega}_\ell}{\omega_\ell} - 1 \right| = o_p(1).
\]
By Slutsky’s theorem, we have
\[
n^{1/2} (\hat{\beta}_\ell - \beta_\ell) / \hat{\omega}_\ell = \frac{n^{1/2} (\hat{\beta}_\ell - \beta_\ell) \omega_\ell}{\hat{\omega}_\ell} \to \mathcal{N}(0, 1).
\]

**A.4.3 Proof of Lemma 4**

**Proof.** Note that
\[
\hat{\omega}_\ell^2 = \sigma_0^2 \theta_\ell \frac{\hat{\Gamma}^T U^T U \hat{\Gamma}}{n} \theta_\ell.
\]
We first prove $\hat{\sigma}_0$ is a consistent estimator of $\sigma_0$ by showing $\hat{\sigma}_0^2 \to \sigma_0^2$ in probability. Note that

$$\left| \hat{\sigma}_0^2 - \sigma_0^2 \right| = \frac{1}{n} ||Y - X\hat{\beta}||_2^2 - \sigma_0^2 = \frac{1}{n} ||X\beta + \eta - X\hat{\beta}||_2^2 - \sigma_0^2$$

$$= \frac{1}{n} ||\eta||_2^2 + \frac{1}{n} ||X\beta - X\hat{\beta}||_2^2 + \frac{2}{n} \eta^T (X\beta - X\hat{\beta}) - \sigma_0^2$$

$$\leq \frac{1}{n} ||\eta||_2^2 - \sigma_0^2 + \frac{||X\beta - X\hat{\beta}||_2^2}{n} + \frac{2||\eta||_2||X\beta - X\hat{\beta}||_2}{n^{1/2}}$$

$$\leq \frac{1}{n} ||\eta||_2^2 - \sigma_0^2 + \frac{64}{\kappa} \frac{s^2 \mu^2}{\kappa} + \frac{2||\eta||_2^2}{n^{1/2}} \frac{s^{1/2} \mu}{\kappa},$$

which holds with probability at least $1 - 234(pqm)^{-1}$ by applying Theorem 2. From Theorem 2, we have

$$\left| \frac{1}{n} ||\eta||_2^2 - \sigma_0^2 \right| \leq 4\sigma_0^2 \left( \frac{\log(pqm)}{n} \right)^{1/2}$$

with probability at least $1 - 2(pqm)^{-2}$, which implies

$$\left| \hat{\sigma}_0^2 - \sigma_0^2 \right| \leq 4\sigma_0^2 \left( \frac{\log(pqm)}{n} \right)^{1/2} + \frac{64}{\kappa} \frac{s^2 \mu^2}{\kappa} + \frac{2||\eta||_2^2}{n^{1/2}} \frac{s^{1/2} \mu}{\kappa}$$

holds with probability at least $1 - 236(pqm)^{-1}$ when $\log(pqm_n)/n \leq 1$. Then we consider

$$\left| \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} - \theta_t^1 \hat{\Gamma}^{U^TU}\Gamma \theta_t \right|$$

$$= \left| \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} - \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} + \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} - \theta_t^1 \hat{\Gamma}^{U^TU}\Gamma \theta_t \right|$$

$$\leq \left| \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} - \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} \right| + \left| \hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} - \theta_t^1 \hat{\Gamma}^{U^TU}\Gamma \theta_t \right|$$

$$\leq \frac{||\hat{\theta}_t||_2^2}{n} \left| \hat{\Gamma}^{U^TU}\hat{\Gamma} - \hat{\Gamma}^{U^TU}\hat{\Gamma} \right| + \frac{\hat{\theta}_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma}}{n} \theta_t - \theta_t^1 \hat{\Gamma}^{U^TU}\Gamma \theta_t$$

$$= T_1 + T_2 + T_3$$

For $T_1$, we know that

$$T_1 \leq ||\hat{\theta}_t||_2 \left| \hat{\Gamma}^{U^TU}\hat{\Gamma} - \hat{\Gamma}^{U^TU}\Gamma \right| \leq 35m_\Omega^2 \lambda_{\max} \sqrt{C_0} \left( \frac{2\rho m}{\rho} \right)^{1/2}$$

with probability at least $1 - 60(pqm)^{-1}$ when $\lambda_{\max} \{2m/\rho \}^{1/2} \leq \sqrt{r} C_0$, where we use the definition of $\hat{\theta}$ in the first inequality and Lemma 15 in the second inequality. For $T_2$, we have

$$T_2 \leq \left| \theta_t^1 \hat{\Gamma}^{U^TU}\hat{\Gamma} \theta_t - \theta_t^1 \hat{\Gamma}^{U^TU}\Gamma \theta_t \right| \leq ||\theta_t||_1 \left| \theta_t - \hat{\theta}_t \right||_1 \left| \hat{\Gamma}^{U^TU} \theta_t \right| \leq m_\Omega^2 \sqrt{C_0} \left| \theta_t - \hat{\theta}_t \right||_1,$$
where we use the fact that
\[
\left| \left( \sum_{j=1}^q f_j \epsilon(Z_j) \right) \left( \sum_{j=1}^q f_j \epsilon(Z_j) \right) \right| \leq r^2 C_0^2.
\]

Applying Lemma 20, we have
\[
T_2 \leq 2m_{\Omega} s \sigma r^2 C_0^2 (2m_{\Omega} u)^{1-b}
\]
with probability at least \(1 - 62 (pqm)^{-1}\), where \(v = 36 m_{\Omega} \lambda_{\max} r C_0 \left( 2rm/\rho \right)^{1/2} \). For \(T_3\), we have
\[
T_3 \leq \left| \theta^T \left( \frac{F^T F}{n} - \frac{\Gamma^T \E(U^T U)}{n} \Gamma \right) \theta \right|
\leq \left\| \theta \right\|_2 \left\| \frac{F^T F}{n} - \frac{\Gamma^T \E(U^T U)}{n} \Gamma \right\|_\infty
\leq m_{\Omega}^2 \left( 3 \frac{n-1}{n} r^2 C_L C_0 m_n - d + \frac{r^2 C_0^2}{n} \right).
\]

which follows from Theorem 3. Therefore, we have
\[
\left| \hat{\omega}^2 - \omega^2 \right| = \left| \hat{\sigma}^2 \hat{\theta}^T \frac{\Gamma^T U^T U \Gamma}{n} \hat{\theta} - \sigma^2 \theta^T \E(U^T U) \Gamma \theta \right|
\leq \left| \hat{\sigma}^2 \hat{\theta}^T \frac{\Gamma^T U^T U \Gamma}{n} \hat{\theta} - \sigma^2 \theta^T \E(U^T U) \Gamma \theta \right| - \sigma^2 \theta^T \E(U^T U) \Gamma \theta \left| \sigma^2 \hat{\theta}^T \frac{\Gamma^T U^T U \Gamma}{n} \hat{\theta} - \sigma^2 \theta^T \E(U^T U) \Gamma \theta \right|
\leq \left| 4 \sigma_{\Omega}^2 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2} + \frac{64}{\kappa^2} s \mu^2 + 2 \sqrt{5 \sigma_{\Omega}^2} \sum_{t} \left( \frac{2 \sqrt{5 \sigma_{\Omega}^2} \sum_{t} \frac{8}{\kappa^{1/2}} \mu \left( \frac{F^T F}{n} - \frac{\Gamma^T \E(U^T U)}{n} \Gamma \right) \theta \right) \sigma_{\Omega}^2 \right|
\leq \left| 4 \sigma_{\Omega}^2 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2} + \frac{64}{\kappa^2} s \mu^2 + 2 \sqrt{5 \sigma_{\Omega}^2} \sum_{t} \left( \frac{2 \sqrt{5 \sigma_{\Omega}^2} \sum_{t} \frac{8}{\kappa^{1/2}} \mu \left( \frac{F^T F}{n} - \frac{\Gamma^T \E(U^T U)}{n} \Gamma \right) \theta \right) \sigma_{\Omega}^2 \right|
\leq m_{\Omega}^2 \left( 3 \frac{n-1}{n} r^2 C_L C_0 m_n - d + \frac{r^2 C_0^2}{n} \right).
\]
Therefore, we get
\[
\left| \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U} \mathbf{\hat{Y}}}{n} - \mathbf{F}^T \mathbf{F} \right|_1 
\leq m_{\Omega}^2 \left( \left| \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U}}{n} - \mathbf{F}^T \mathbf{F} \right|_1 + \left| \mathbf{F}^T \mathbf{F} \right|_1 \right)
\leq 35m_{\Omega}^2 \lambda_{\max}^r \mathbf{C}_0 \left\{ \frac{2}{\rho} \right\}^{1/2} + m_{\Omega}^2 \rho C_0^2.
\]

Therefore, we get
\[
|\hat{\omega}_t^2 - \omega_t^2| \leq \left[ 4\sigma_0^2 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2} + \frac{64}{n^2} \mu^2 + 2\sqrt{5\sigma_0} \frac{8}{\kappa} s^{1/2} \mu \right]
\cdot \left[ 35m_{\Omega}^2 \lambda_{\max}^r \mathbf{C}_0 \left\{ \frac{2}{\rho} \right\}^{1/2} + m_{\Omega}^2 \rho C_0^2 \right]
+ \sigma_0^2 \left[ 35m_{\Omega} \lambda_{\max}^r \mathbf{C}_0 \left\{ \frac{2}{\rho} \right\} + 2c_5m_{\Omega} s_{\Omega}\rho C_0^2 (2m_{\Omega} s_{\Omega})^{1-b} + m_{\Omega}^2 \left( \frac{2n - 1}{n} r^2 \mathbf{C}_0 \mathbf{m}_n \frac{d}{n} + \frac{r^2 C_0^2}{n} \right) \right].
\]

\[\square\]

A.5 Control of Remainder Terms
We derive specific conditions to make sure the remainder terms satisfy \( \| R_k \|_\infty = o_p(1) \), \( k = 1, 2, 3, 4 \). We first find the probability of the event \( \| \hat{\Omega} \hat{\Sigma}_d - I \|_\infty = o_p(1) \).

**Lemma 17.** Suppose Assumption 5 holds, then
\[
\| \hat{\Omega} \hat{\Sigma}_d - I \|_\infty \leq m_{\Omega}^2 \lambda_{\max}^r \mathbf{C}_0 \left\{ \frac{2}{\rho} \right\}^{1/2}
\]
holds with probability at least \( 1 - 62(pqm)^{-1} \), when \( \lambda_{\max}(2m/\rho)^{1/2} \leq r^{1/2} C_0 \).

**Proof.** Note that
\[
\| \hat{\Omega} \hat{\Sigma}_d - I \|_\infty = \| \hat{\Omega} \left\{ \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U}}{n} - \mathbf{F}^T \mathbf{F} \right\} \|_\infty
\leq \| \hat{\Omega} \|_1 \left| \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U}}{n} - \mathbf{F}^T \mathbf{F} \right|_1
\leq m_{\Omega} \| \Sigma_f \|_\infty \left| \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U}}{n} - \mathbf{F}^T \mathbf{F} \right|_1
\leq m_{\Omega} \left( \| \Sigma_f \|_\infty + \left| \frac{\mathbf{\hat{Y}}^T \mathbf{U}^T \mathbf{U}}{n} - \mathbf{F}^T \mathbf{F} \right|_1 \right).
\]
From Lemma 14, we have
\[
\left\| \Sigma_f - \frac{F^T F}{n} \right\|_\infty \leq 4r^2 C_0^2 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2}
\]
with probability at least \( 1 - 2p^2 \) \((pqm)^{-4} \). Also, from Lemma 15, we have
\[
\left\| \frac{F^T F}{n} - \frac{\hat{X}^T \hat{X}}{n} \right\|_\infty \leq 35\lambda_{\text{max}} r C_0 \left( \frac{2rm}{\rho} \right)^{1/2}
\]
with probability at least \( 1 - 60(pqm)^{-1} \), when \( \lambda_{\text{max}} (2m/\rho)^{1/2} \leq r^{1/2} C_0 \). Therefore, we have
\[
\left\| \Omega_f - I \right\|_\infty \leq m q_0^2 36 \lambda_{\text{max}} r C_0 \left( \frac{2rm}{\rho} \right)^{1/2}
\]
with probability at least \( 1 - 62(pqm)^{-1} \) when \( \lambda_{\text{max}} (2m/\rho)^{1/2} \leq r^{1/2} C_0 \).

By Lemma 17, \( v \) can be chosen as \( 36 m q_0^2 \lambda_{\text{max}} r C_0 \sqrt{(2m/\rho)} \).

The next result provides a probabilistic bound for \( \left\| U^T \eta / n \right\|_\infty \).

**Lemma 18.**
\[
P\left[ \frac{\left\| U^T \eta \right\|_\infty}{n} \leq 4\left\{ \log(pqm/n) \right\}^{1/2} \right] \geq 1 - (pqm)^{-1}.
\]

**Proof.** Write \( \frac{\left\| U^T \eta \right\|_\infty}{n} \) as \( \frac{\left\| U^T \eta \right\|_\infty}{n} = \max_{j,k} \left| U^T_{jk} \eta \right| \), where \( U^T_{jk} \) is the \( k \)th column of spline matrix \( U^T \). Recall the Gaussian tail bound
\[
P(|X| \geq t) \leq 2 \left( \frac{2}{\pi} \right)^{1/2} \exp\left\{ -\frac{t^2}{2} \right\}.
\]

Now we have
\[
P\left( \frac{\left\| U^T \eta \right\|_\infty}{n} \geq t \right) \leq qm n P \left( \left| U^T_{jk} \eta \right| \geq t \right)
\]
\[= qm n P \left[ \frac{\left| U^T_{jk} \eta \right|}{n} \geq t \right] = qm n P \left[ \left| \sum_{i=1}^n \psi_k(Z_{ij}) \right| \geq 2 \frac{n t^2}{2 \sigma_0^2 \sum_{i=1}^n \psi_k^2(Z_{ij})} \right]
\]
\[\leq qm n \left( 2 \frac{t^2}{\sigma_0^2 \sum_{i=1}^n \psi_k^2(Z_{ij})} \right)^{1/2} \exp \left\{ -\frac{nt^2}{2 \sigma_0^2} \right\} \leq qm (pqm)^{-1}.
\]

Since \( |\psi_k(Z_{ij})| \leq 2 \), setting \( t = 4\sigma_0 \left\{ \log(pqm/n) \right\}^{1/2} \), we obtain
\[
P\left[ \frac{\left\| U^T \eta \right\|_\infty}{n} \geq 4\sigma_0 \left\{ \log(pqm/n) \right\}^{1/2} \right] \leq qm (pqm)^{-1}.
\]

**Lemma 19** (Lemma A.1 in Gold, Lederer, and Tao, 2020). Suppose (i) \( \| \Omega \|_1 \) is bounded above by a constant \( m_\Omega < \infty \), and (ii) \( \hat{\Omega} \) is an estimate of \( \Omega \) with rows \( \hat{\theta}_t \) obtained as solutions to (5). Then
\[
\| \hat{\Omega} - \Omega \|_\infty \leq 2m_\Omega v
\]
holds with probability at least \( 1 - 62(pqm)^{-1} \).
Proof. Under the conditions of this Lemma, we know that
\[ \|\hat{\Omega} \hat{\Sigma}_d - I\|_{\infty} \leq \nu, \quad \|\hat{\Omega} \hat{\Sigma}_d - I\|_{\infty} \leq \nu. \]
Then, we have
\[
\begin{align*}
\Omega - \hat{\Omega} &= \left\{ I - \hat{\Omega} \mathbb{E} \left( \frac{F^T F}{n} \right) \right\} \Omega = \left[ I + \hat{\Omega} \left\{ \hat{\Sigma}_d - \mathbb{E} \left( \frac{F^T F}{n} \right) \right\} - \hat{\Omega} \hat{\Sigma}_d \right] \Omega \\
&= (I - \hat{\Omega} \hat{\Sigma}_d) \Omega - \hat{\Omega} \left\{ \mathbb{E} \left( \frac{F^T F}{n} \right) - \hat{\Sigma}_d \right\} \Omega = (I - \hat{\Omega} \hat{\Sigma}_d) \Omega - \hat{\Omega} (I - \hat{\Sigma}_d \Omega).
\end{align*}
\]
By Hölder’s inequality, we have
\[
\hat{\Omega} (I - \hat{\Sigma}_d \Omega) \leq \|I - \hat{\Sigma}_d \Omega\|_{\infty} \|\hat{\Omega}^T\|_1 \leq \|I - \hat{\Sigma}_d \Omega\|_{\infty} \|\Omega^T\|_1 \leq m_{\Omega} \nu
\]
and
\[
\| (I - \hat{\Omega} \hat{\Sigma}_d) \Omega \|_{\infty} \leq \|\Omega\|_1 \|I - \hat{\Omega} \hat{\Sigma}_d\|_{\infty} \leq m_{\Omega} \nu.
\]
Therefore, we have
\[
\|\Omega - \hat{\Omega}\|_{\infty} \leq 2m_{\Omega} \nu.
\]
We have shown in Lemma 17 that
\[
\|\hat{\Omega} \hat{\Sigma}_d - I\|_{\infty} \leq 36m_{\Omega} \lambda_{\text{max}} r C_0 \left( \frac{2rm}{\rho} \right)^{1/2}
\]
with probability at least \(1 - 62(pqm)^{-1}\). Therefore, the proof is complete by choosing \(\nu = 36m_{\Omega} \lambda_{\text{max}} r C_0 (2rm/\rho)^{1/2}\). \(\Box\)

Lemma 20 (Lemma A.2 in Gold, Lederer, and Tao, 2020). Suppose, in addition to the conditions of Lemma 19, \(\Omega \in U(m_{\Omega}, b, s_{\Omega})\). Then,
\[
\|\hat{\theta}_\ell - \theta\|_1 \leq 2c_b (2m_{\Omega} \nu)^{1-b} s_{\Omega}
\]
for each \(\ell \in \{1, \ldots, p\}\), where \(c_b = 1 + 2^{1-b} + 3^{1-b}\).

Proof. See the proof of Theorem 6 in [6]. \(\Box\)

Now we examine each remainder term \(R_k\) in the following subsections.

A.5.1 Control of \(R_1\)

Lemma 21. Suppose the conditions of Theorem 2 and Lemma 20 hold. If
\[
v^{1/2} 2c_b (2m_{\Omega} \nu)^{1-b} s_{\Omega} \left[ 4\sqrt{5} \sigma_0 r C_L m_n^{-d} + 14C_0 \sigma_0 \left( \frac{r^2 \log(pqm)}{n} \right)^{1/2} \right] = o(1),
\]
then \(\|R_1\|_{\infty} = o(1)\) with probability at least \(1 - 5(pqm)^{-1}\).
Proof. Note that

\[ R_1 = (\tilde{\Omega} - \Omega)D^\top \eta/n^{1/2} = (\tilde{\Omega} - \Omega) (\Gamma^\top U^\top - F^\top) \eta/n^{1/2} \]
\[ \leq \|\tilde{\Omega} - \Omega\|_1 \left( \|\Gamma^\top U^\top - F^\top\|_1 \eta/n^{1/2} + \|F^\top\eta/n^{1/2}\|_\infty \right) \]
\[ = n^{1/2} \|\tilde{\Omega} - \Omega\|_1 \left( \|\Gamma^\top U^\top - F^\top\|_1 \eta/n^{1/2} + \|F^\top\eta/n^{1/2}\|_\infty \right). \]

As is shown in the proof of Theorem 2, \( \|F^\top\eta/n\|_\infty \leq 2C_0\sigma_0 \{r^2 \log(pqm)/n\}^{1/2} \) holds with probability at least \( 1 - p(pqm)^{-2} \). Applying Lemma 13 and the \( \chi^2 \) concentration bound, we have

\[ \|\Gamma^\top U^\top - F^\top\|_1 \eta/n^{1/2} \leq \frac{1}{n^{1/2}} \max_\ell \left\| U\gamma_{\ell} - \sum_{j=1}^q F_{j\ell} \right\|_2 \max_\ell \frac{\|\eta\|_2}{n^{1/2}} \]
\[ \leq 4\sqrt{5\sigma_0 r C_L \Gamma_{n}^{-d}} + 4r\sigma_0 \{5C_0^2 \log(pqm)/n\}^{1/2} \]
with probability at least \( 1 - 4r(pqm)^{-2} \). It follows that

\[ R_1 \leq n^{1/2} \|\tilde{\Omega} - \Omega\|_1 \|F^\top\eta/n\|_\infty \]
\[ \leq n^{1/2} 2\sigma_0(2m_{\Omega}^{1/2})^{3/2} \sigma_0 \left[ 4\sqrt{5\sigma_0 r C_L \Gamma_{n}^{-d}} + 14C_0\sigma_0 \left\{ \frac{r^2 \log(pqm)}{n} \right\}^{1/2} \right] \]
holds with probability at least \( 1 - 5(pqm)^{-1} \). \( \square \)

A.5.2 Control of \( R_2 \)

**Lemma 22.** Under the same conditions of Lemma 21, if

\[ m_{\Omega}^{128r} \lambda_{\text{max}} \{ \log(pqm) \}^{1/2} \frac{m_n^{3/2}}{\rho} = o(1), \]
then \( \|R_2\|_\infty = o(1) \) with probability at least \( 1 - 19(pqm)^{-1} \).

**Proof.** Note that

\[ \|R_2\|_\infty = \tilde{\Omega}(\tilde{\Gamma}^\top U^\top - \Gamma^\top U^\top) \eta/n^{1/2} \]
\[ \leq n^{1/2} \|\tilde{\Omega} - \Omega\|_1 \|\tilde{\Gamma} - \Gamma\|_1 \|U^\top \eta/n\|_\infty \]
\[ \leq n^{1/2} m_{\Omega} \max_{\ell=1,\ldots,p} \|\tilde{\gamma}_\ell - \gamma_\ell\|_1 \|U^\top \eta/n\|_\infty. \]

Recall from the proof of Theorem 1

\[ \max_{\ell=1,\ldots,p} \|\tilde{\gamma}_\ell - \gamma_\ell\|_1 \leq \max_\ell m_1^{1/2} \sum_{j=1}^q \|\tilde{\gamma}_{j\ell} - \gamma_{j\ell}\|_2 \leq m_1^{1/2} 32r \lambda_{\text{max}} \frac{m}{\rho} \]
holds with probability at least \( 1 - 18(pqm)^{-1} \). Then, by Lemma 18, we obtain

\[ \|U^\top \eta/n\|_\infty \leq 4 \left\{ \frac{\log(pqm)}{n} \right\}^{1/2} \]
with probability at least \( 1 - (pqm)^{-1} \). It follows that

\[ \|R_2\|_\infty \leq m_{\Omega}^{128r} \lambda_{\text{max}} \{ \log(pqm) \}^{1/2} \frac{m_n^{3/2}}{\rho} \]
holds with with probability at least \( 1 - 19(pqm)^{-1} \). \( \square \)
A.5.3 Control of $R_3$

Lemma 23. Under the same conditions of Lemma 21, if

$$n^{1/2}m_\Omega \lambda_{\max} \left( \frac{2rm}{\rho} \right)^{1/2} (30rC_0 + 16 \max_\ell \sigma_\ell) \frac{64}{\kappa^2} s \mu = o(1),$$

then $\|R_3\|_\infty = o(1)$ with probability at least $1 - 277(pqm)^{-1}$.

Proof. We first apply Hölder’s inequality to get

$$\|R_3\|_\infty \leq n^{1/2} ||\hat{\Gamma}^T||_1 \|\hat{\Gamma}^T(X - \hat{D})/n\|_\infty \|\hat{\beta} - \beta\|_1.$$ 

Note that

$$\hat{D}^T(X - \hat{D})/n = \hat{D}^T(F + E - \hat{D})/n \leq \hat{D}^T(F - \hat{D})/n + \hat{D}^T E/n.$$

For the first term on the right-hand side above, we have

$$||\hat{\Gamma}^T U^T(F - \hat{D})/n||_\infty \leq ||\hat{\Gamma}^T(U^T - F^T)(F - \hat{D})/n||_\infty \leq \max_{\ell,\ell'} \frac{\sum_{j=1}^q F_{\ell j}}{n^{1/2}} \|\sum_{j=1}^q F_{\ell j} - U_{\ell j} \gamma_{\ell j} \|_2 + \max \frac{\sum_{j=1}^q F_{\ell j} - U_{\ell j} \gamma_{\ell j} \|_2}{n^{1/2}}$$

$$\leq rC_0 5 \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} + 25 \lambda_{\max}^2 r \left( \frac{2m}{\rho} \right)^{1/2} \leq 30 \lambda_{\max} r^{3/2} C_0 \left( \frac{2m}{\rho} \right)^{1/2},$$

which holds with probability at least $1 - 20(pqm)^{-1}$ when $\lambda_{\max} r^{1/2}(2m/\rho)^{1/2} \leq C_0$. For the second term, we have

$$||\hat{\Gamma}^T E/n||_\infty = ||\hat{\Gamma}^T U^T E/n||_\infty \leq ||\hat{\Gamma}^T(U^T - F^T) E/n||_\infty + ||F^T E/n||_\infty \leq \max_{\ell,\ell'} \frac{\sum_{j=1}^q F_{\ell j}}{n^{1/2}} \|\sum_{j=1}^q F_{\ell j} - U_{\ell j} \gamma_{\ell j} \|_2 + \|F^T E/n||_\infty$$

$$\leq 5 \sqrt{5} \lambda_{\max} \max_{\ell} \sigma_{\ell} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} + \|F^T E/n||_\infty \leq 5 \sqrt{5} \max_{\ell} \sigma_{\ell} \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2} + \max_{\ell} \sigma_{\ell} C_0 \{8r^2 \log(pqm)/n\}^{1/2}$$

$$\leq 16 \max_{\ell} \sigma_{\ell} \lambda_{\max} r^{1/2} \left( \frac{2m}{\rho} \right)^{1/2}$$

with probability at least $1 - 23(pqm)^{-1}$, where we use the arguments in the proof of Theorem 2 when bounding $\|T_3\|_\infty$ and $\|T_4\|_\infty$. It follows that

$$\|\hat{D}^T(X - \hat{D})/n\|_\infty \leq \lambda_{\max} \left( \frac{2rm}{\rho} \right)^{1/2} (30rC_0 + 16 \max_\ell \sigma_\ell)$$

holds with probability at least $1 - 43(pqm)^{-1}$. Finally, we have

$$\|R_3\|_\infty \leq n^{1/2} ||\Gamma^T||_1 \|\hat{D}^T(D - \hat{D})/n\|_\infty \|\hat{\beta} - \beta\|_1 \leq n^{1/2} m_\Omega \lambda_{\max} \left( \frac{2rm}{\rho} \right)^{1/2} (30rC_0 + 16 \max_\ell \sigma_\ell) \frac{64}{\kappa^2} s \mu$$

with probability at least $1 - 277(pqm)^{-1}$. □
A.5.4 Control of $R_4$

**Lemma 24.** Under the same conditions of Lemma 21, if

$$n^{1/2}36m\omega\lambda_{\text{max}}rC_0\left(\frac{2rm}{\rho}\right)^{1/2}64\frac{\mu}{\kappa^2}s = o(1),$$

then $\|R_4\|_\infty = o(1)$ with probability at least $1 - 296(pqm)^{-1}$.

**Proof.** By Hölder’s inequality, we have

$$\|R_4\|_\infty \leq n^{1/2}\|\tilde{\Omega}_{\tilde{\Sigma}} - I\|_\infty \|\tilde{\beta} - \beta\|_1.$$

Applying Lemma 17, we obtain

$$\|R_4\|_\infty \leq n^{1/2}36m\omega\lambda_{\text{max}}rC_0\left(\frac{2rm}{\rho}\right)^{1/2}\|\tilde{\beta} - \beta\|_1,$$

which holds with probability at least $1 - 62(pqm)^{-1}$ when $\lambda_{\text{max}}(2m/\rho)^{1/2} \leq r^{1/2}C_0$. Apply Theorem 2 to get

$$\|R_4\|_\infty \leq n^{1/2}36m\omega\lambda_{\text{max}}rC_0\left(\frac{2rm}{\rho}\right)^{1/2}64\frac{\mu}{\kappa^2},$$

which holds with probability at least $1 - 296(pqm)^{-1}$.

\[\Box\]

B Additional Experiments

In this section, we present more experiments to demonstrate the finite sample performance of our proposed estimator when the dimensions of the treatment and instrumental variables are large.
