SEQUENT CALCULI OF FINITE DIMENSION

A. BUCCIARELLI, A. LEDDA, F. PAOLI, AND A. SALIBRA

Abstract. In recent work, the authors introduced the notion of $n$-dimensional Boolean algebra and the corresponding propositional logic $n$CL. In this paper, we introduce a sequent calculus for $n$CL and we show its soundness and completeness.

1. Introduction

Equational consequence relations are a major recurring theme in the research activity of Janusz Czelakowski (see e.g. [10, Q.4] and the work related therein), in so far as this topic reaches out to several other areas that he always regarded as crucial for algebraic logic: to name but a few, quasivarieties of algebras, equational logic, and the deduction theorem. In particular, the equational consequence relation of Boolean algebras appears to be extremely well-behaved in many respects. This is not surprising, since Boolean algebras encompass virtually all the "desirable" properties one can expect from a variety. Although many of these properties can be accounted for within the theory of pointed discriminator varieties generated by a single primal algebra, such a framework does not explain them entirely.

A research programme developed by the present authors over the last few years [34, 21, 36, 7, 33, 8] has attempted to single out the features of Boolean algebras that are responsible for this state of affairs. A Church algebra is an algebra $A$ with a term definable operations $q$ (ternary) and $0$, $1$ (nullary), such that for every $a, b \in A$, $q(1, a, b) = a$ and $q(0, a, b) = b$. The ternary operation $q$ intends to formalise the "if-then-else" construct, widely employed in computer science. An element $e$ of a Church algebra $A$ is called 2-central if $A$ can be decomposed as the product $A/\theta(e, 0) \times A/\theta(e, 1)$, where $\theta(e, 0)$ ($\theta(e, 1)$) is the smallest congruence on $A$ that collapses $e$ and $0$ ($e$ and $1$). According to a well-known result in the elementary structure theory of Boolean algebras, all elements of a Boolean algebra are 2-central. More generally, Church algebras where every element is 2-central were called Boolean-like algebras in [34], since the variety of all such algebras in
the language \((q, 0, 1)\) is term-equivalent to the variety of Boolean algebras. In [33, 8] and in the present paper, on the other hand, they are called \emph{Boolean algebras of dimension 2}.

This approach can be generalised to algebras \(A\) having \(n\) designated elements \((n \geq 2)\) and an \(n + 1\)-ary operation (a sort of ”generalised if-then-else”) that induces a decomposition of \(A\) into \(n\), rather than just 2, factors. In [33, 8], naturally enough, these algebras were called \emph{Church algebras of dimension \(n\) (\(n\)CHs)}, while algebras \(A\) all of whose elements induce an \(n\)-ary factorisation of this sort were given the name of \emph{Boolean algebras of dimension \(n\) (\(n\)BAs)}. Free \(\mathcal{V}\)-algebras (for \(\mathcal{V}\) a variety), lambda abstraction algebras, semimodules over semirings — hence, in particular, Boolean vector spaces — give rise to \(n\)CHs, where \(n\) is generally greater than 2. The notion of a 2-central element can be naturally extended to that of an \(n\)-central element in an \(n\)CH. Since \(n\)-central elements are equationally definable, the \(n\)BAs of a specified type form a variety, which happens to share many remarkable properties with the variety of Boolean algebras. In particular:

- all subdirectly irreducible \(n\)BAs have the same finite cardinality; moreover, any \(n\)BA is a subdirect product of a finite family of algebras of cardinality \(n\);
- any \(n\)BA whose type includes just the generalised if-then-else and the \(n\) constants is a subdirect power of the \(n\)-element algebra \(n\) of ”generalised truth values”;
- For every \(n \geq 2\), all \(n\)BAs of cardinality \(n\) are primal, and every variety generated by an \(n\)-element primal algebra is a variety of \(n\)BAs.

In [8] the theory of \(n\)-central elements was put to good use to yield an extension to arbitrary semirings of the technique of \emph{Boolean powers}. We defined the semiring power \(A[R]\) of an algebra \(A\) by a semiring \(R\), and showed that any \(n\)BA \(A\) in the variety generated by \(n\) is isomorphic to the semiring power \(A[B_A]\) of \(A\) by the Boolean algebra \(B_A\) of 2-central elements of \(A\). Foster’s celebrated theorem on primal algebras follows as a corollary from this result.

In [33] we focused on an application to logic. Just like Boolean algebras are the algebraic counterpart of classical propositional logic \(CL\), for every \(n \geq 2\) we defined a logic \(nCL\) whose algebraic counterpart are \(n\)BAs. We also proved that every tabular logic with a single designated value is a sublogic of some \(nCL\). Although we provided Hilbert-style calculi for each \(nCL\), the proof theory of these logics was not investigated in detail.

In the present paper, we intend to develop more perspicuous calculi for the logics \(nCLs\), which may afford better insights into the behaviour of higher-dimensional logical connectives. The proof-theoretic framework of Gentzen’s \emph{sequent calculi} appears as a promising candidate to achieve such a goal. Under optimal conditions, such as we find in classical logic, it may yield an algorithmic presentation
of the equational consequence relation of Boolean algebras, via the derivability relation of a logical calculus that is equivalent (in the sense of [4]) to it. While it is relatively easy to transform the sequent calculus for classical logic into a calculus for the equivalent logic 2CL, logics with a dimension greater than 2 present trickier challenges.

To face these issues, we introduce the framework of higher-dimensional calculi. Although our approach appears to be new, it presents similarities with other proof-theoretic methods available in the literature. In particular:

• A successful generalisation of Gentzen’s sequent calculi to finite-valued logics, dating back to Rousseau [32], consists in replacing 2-sided sequents $\Gamma \Rightarrow \Delta$ by $n$-sided sequents $\Gamma_1 | \ldots | \Gamma_n$, one for each different truth value. The rules for each connective can be directly read off the truth table of the connective itself, which dictates what side of the conclusion-sequent should host the principal formula depending on the whereabouts of the auxiliary formulas in the premiss-sequents. Clearly, this process can be entirely automated: the programme Multlog (https://www.logic.at/multlog/) generates a $n$-sided calculus for any finite-valued logic whose truth tables are given as input [1]. Here, instead, we keep Gentzen’s 2-sided sequents but we split the turnstile $\vdash$ into $n$ different turnstiles $\vdash_i$ ($1 \leq i \leq n$), one for each truth value $e_i$ of the calculus.

• Ordinary sequent calculi for a logic $L$ aim at generating the $L$-valid sequents and, in particular, the tautologies of $L$; refutation systems (see e.g. [17] for a survey) aim at generating the $L$-antivalent sequents and, in particular, the contradictions of $L$. In the literature, a number of hybrid deduction-refutation systems have been proposed [16, 31, 18], characterised by the presence of two different turnstiles $\vdash$ and $\dashv$ for deduction and refutation, respectively. The rules of these calculi, generally speaking, admit the simultaneous presence, as premisses or conclusions, of sequents formed with both turnstiles. In our calculus this idea is further generalised in so far as each truth value has its own associated turnstile.

Outline of the paper. In Section 2 we recapitulate a few notions from our previous papers on the subject, to make the present work reasonably self-contained. In particular, we give the definitions of Church algebras, and of Boolean algebras, of finite dimension, summarising the main results thus far obtained about them. In Section 3 we introduce the $n$-dimensional propositional calculi for each $n$CL and their semantics, giving a soundness proof. Section 4 contains the completeness proof. In Section 5 which precedes a short concluding section, we specialise our results to the 2-dimensional case.
2. Preliminaries

2.1. Church algebras of finite dimension. In [33] we introduced Church algebras of dimension \( n \), algebras having \( n \) designated elements \( e_1, \ldots, e_n \) \( (n \geq 2) \) and an operation \( q \) of arity \( n+1 \) (a sort of “generalised if-then-else”) satisfying \( q(e_i, x_1, \ldots, x_n) = x_i \). The operator \( q \) induces, through the so-called \( n \)-central elements, a decomposition of the algebra into \( n \) factors.

Definition 1. An algebra \( A \) of type \( \tau \) is a Church algebra of dimension \( n \) (an \( n \)-CH, for short) if there are term definable elements \( e_1^A, e_2^A, \ldots, e_n^A \in A \) and a term operation \( q^A \) of arity \( n+1 \) such that, for all \( b_1, \ldots, b_n \in A \) and \( 1 \leq i \leq n \), \( q^A(e_1^A, b_1, \ldots, b_n) = b_i \). A variety \( V \) of type \( \tau \) is a variety of algebras of dimension \( n \) if every member of \( V \) is an \( n \)-CH with respect to the same terms \( q, e_1, \ldots, e_n \).

If \( A \) is an \( n \)-CH, then \( A_0 = (A, q^A, e_1^A, \ldots, e_n^A) \) is the pure reduct of \( A \).

Church algebras of dimension 2 were introduced as Church algebras in [26] and studied in [31]. Examples of Church algebras of dimension 2 are Boolean algebras (with \( q(x, y, z) = (x \land z) \lor (\neg x \land y) \)) or rings with unit (with \( q(x, y, z) = xz + y - xy \)). Next, we list some relevant examples of Church algebras having dimension greater than 2.

Example 1. (\( n \)-Sets) Let \( X \) be a set. An \( n \)-subset of \( X \) is a sequence \( (Y_1, \ldots, Y_n) \) of subsets \( Y_i \) of \( X \). We denote by \( \text{Set}_n(X) \) the family of all \( n \)-subsets of \( X \). \( \text{Set}_n(X) \) can be viewed as the universe of a Church algebra of dimension \( n \) where, for all \( y^i = (Y_1^i, \ldots, Y_n^i) \):

\[
q(y^0, y^1, \ldots, y^n) = \bigcup_{i=1}^n Y_i^0 \cap Y_i^1 \cap \cdots \cap Y_i^n.
\]

In [31], Vaggione introduced the notion of a central element to study algebras whose complementary factor congruences can be replaced by certain elements of their universes. If a neat description of such elements is available, one usually gets important insights into the structure theories of the algebras at issue. To list a few examples, central elements coincide with central idempotents in rings with unit, with complemented elements in \( FL_{ew} \)-algebras, which form the equivalent algebraic semantics of the full Lambek calculus with exchange and weakening, and with members of the centre in ortholattices. In [31], T. Kowalski and three of the present authors investigated central elements in Church algebras of dimension 2. In [33], the idea was generalised to Church algebras of arbitrary finite dimension.

Definition 2. If \( A \) is an \( n \)-CH, then \( c \in A \) is called \( n \)-central if the sequence of congruences \( (\theta(c, e_1), \ldots, \theta(c, e_n)) \) is an \( n \)-tuple of complementary factor congruences of \( A \). A central element \( c \) is nontrivial if \( c \notin \{e_1, \ldots, e_n\} \).

The following characterisation of \( n \)-central elements, as well as the subsequent elementary result about them, were also proved in [33].
Theorem 1. If $A$ is an $n$CH of type $\tau$ and $c \in A$, then the following conditions are equivalent:

1. $c$ is $n$-central;
2. $\cap_{i \leq n} \theta(c, e_i) = \Delta$;
3. for all $a_1, \ldots, a_n \in A$, $q(c, a_1, \ldots, a_n)$ is the unique element such that $a_i \theta(c, e_i) q(c, a_1, \ldots, a_n)$, for all $1 \leq i \leq n$;
4. The following conditions are satisfied:
   \begin{align*}
   &B1: q(c, e_1, \ldots, e_n) = c. \\
   &B2: q(c, x, x, \ldots, x) = x \text{ for every } x \in A. \\
   &B3: \text{If } \sigma \in \tau \text{ has arity } k \text{ and } x \text{ is a } n \times k \text{ matrix of elements of } A, \text{ then } q(c, \sigma(x_1), \ldots, \sigma(x_n)) = \sigma(q(c, x_1), \ldots, q(c, x_k)).
   
   &B4: q(c, q(c, x_1), \ldots, q(c, x_n)) = q(c, x_1, x_2, \ldots, x_n).
   
   &B5: f_c, \text{ defined by } f_c(x_1, \ldots, x_n) = q(c, x_1, \ldots, x_n), \text{ is a decomposition operator on } A \text{ such that } f_c(e_1, \ldots, e_n) = c.
   
5. The function $f_c$, defined by $f_c(x_1, \ldots, x_n) = q(c, x_1, \ldots, x_n)$, is a decomposition operator on $A$ such that $f_c(e_1, \ldots, e_n) = c$.

For any $n$-central element $c$ and any $n \times n$ matrix $x$ of elements of $A$, a direct consequence of (B1)-(B3) gives

$B4$: $q(c, q(c, x_1), \ldots, q(c, x_n)) = q(c, x_1, x_2, \ldots, x_n)$.

Proposition 1. Let $A$ be an $n$CH. Then the set of all $n$-central elements of $A$ is a subalgebra of the pure reduct of $A$.

2.2. Boolean-like algebras of finite dimension. Boolean algebras are Church algebras of dimension 2 all of whose elements are 2-central. It turns out that, among the $n$-dimensional Church algebras, those algebras all of whose elements are $n$-central inherit many of the remarkable properties that distinguish Boolean algebras.

Definition 3. An $n$CH $A$ is called a Boolean-like algebra of dimension $n$ ($n$BA, for short) if every element of $A$ is $n$-central.

By Proposition 1 the algebra $\text{Ce}_n(A)$ of all $n$-central elements of an $n$CH $A$ is a canonical example of $n$BA. The class of all nBAs of type $\tau$ is a variety of nCHs axiomatised by the identities B1-B3 in Theorem 1.

Example 2. The algebra $n = (\{e_1, \ldots, e_n\}, q^n, e^n_1, \ldots, e^n_n)$, where

$q^n_i(e_i, x_1, \ldots, x_n) = x_i$

for every $i \leq n$, is a pure $n$BA.

Example 3. $(n$-Partitions$)$ Let $X$ be a set. An $n$-partition of $X$ is an $n$-subset $(Y_1, \ldots, Y_n)$ of $X$ such that $\bigcup_{i=1}^n Y_i = X$ and $Y_i \cap Y_j = \emptyset$ for all $i \neq j$. The set of $n$-partitions of $X$ is closed under the $q$-operator defined in Example 1 and

constitutes the algebra of all \( n \)-central elements of the \( n \text{CH} \) Set\(_n(X) \) of all \( n \)-subsets of \( X \). Notice that the algebra of \( n \)-partitions of \( X \), denoted by \( \text{Par}(X) \), is isomorphic to the \( n \text{BA} \) \( n^X \).

Several remarkable properties of Boolean algebras find some analogue in the structure theory of \( n \text{BAs} \).

**Theorem 2.**  
1. An \( n \text{BA} \) \( A \) is subdirectly irreducible if and only if \( |A| = n \).
2. Any variety \( V \) of \( n \text{BAs} \) is generated by the finite set \( \{A \in V : |A| = n\} \). In particular, the variety of pure \( n \text{BAs} \) is generated by the algebra \( n \).
3. If an \( n \text{BA} \) \( A \) has a minimal subalgebra \( E \) of cardinality \( n \), then \( V(A) = V(E) \).
4. Every \( n \text{BA} \) \( A \) is isomorphic to a subdirect product of \( B_{I_1}^{I_1} \times \cdots \times B_{I_k}^{I_k} \) for some sets \( I_1, \ldots, I_k \) and some \( n \text{BAs} \) \( B_1, \ldots, B_k \) of cardinality \( n \).
5. Every pure \( n \text{BA} \) \( A \) is isomorphic to a subdirect power of \( n^I \), for some set \( I \).

However, we cannot assume that any two \( n \)-element algebras in an arbitrary variety \( V \) of \( n \text{BAs} \) are isomorphic, for such algebras may have further operations over which we do not have any control.

A subalgebra of the \( n \text{BA} \) \( \text{Par}(X) \) of the \( n \)-partitions on a set \( X \), defined in Example 3, is called a field of \( n \)-partitions on \( X \). The Stone representation theorem for \( n \text{BAs} \) follows.

**Corollary 1.** Any pure \( n \text{BA} \) is isomorphic to a field of \( n \)-partitions on a suitable set \( X \).

The notion of multideal plays an important role in the theory of \( n \text{BA} \)’s, like the one of ideal does for Boolean algebras. Multideals are introduced and studied in [7]. Here we recall the definition, and we state a proposition needed for future use.

**Definition 4.** Let \( A \) be a \( n \text{BA} \). A multideal is a \( n \)-partition \( (I_1, \ldots, I_n) \) of a subset \( I \) of \( A \) such that

1. \( e_k \in I_k \);
2. \( a \in I_r, b \in I_k \) and \( c_1, \ldots, c_n \in A \) imply \( q(a, c_1, \ldots, c_{r-1}, b, c_{r+1}, \ldots, c_n) \in I_k \);
3. \( a \in A \) and \( c_1, \ldots, c_n \in I_k \) imply \( q(a, c_1, \ldots, c_n) \in I_k \).

The set \( I \) is called the carrier of the multideal. An ultramultideal of \( A \) is a multideal whose carrier is \( A \).

**Proposition 2** ([7]). Every multideal is the intersection of all ultramultideals containing it.
3. The $n$-dimensional Propositional Calculus

In this section we introduce the $n$-dimensional propositional calculus, $n$PC in the sequel. The deduction rules of $n$PC are given in Figure 1. The distinctive feature of this deductive system is that each dimension $i \in \hat{n} = \{1, 2, \ldots, n\}$ has its own turnstyle $\vdash_i$. In the two dimensional case, this gives rise to the turnstyles $\vdash_1$ and $\vdash_2$, the former deriving tautologies, and the latter deriving contradictions.

Entailments in the various dimensions are symmetric, in the sense expressed by the rule (Sym) of Figure 1 that can be instantiated as follows, for $n = 2$ and for a given propositional formula $F$:

$$
\begin{array}{c}
\vdash_1 F \\
\vdash_2 F^{(12)}
\end{array}
$$

where $F^{(12)}$ is the negation of $F$, obtained by switching the truth values in $F^{[1]}$. The rule above is usually written as follows:

$$
\begin{array}{c}
\vdash F \\
\vdash \neg F
\end{array}
$$

In the case $n = 2$ there is a unique way of switching the truth values, whereas in general there are $\binom{n}{2}$ possible “negations”, and more generally there are $n! - 1$ ways of perturbing a formula by permuting the truth values in it. The permutations, and in particular the exchanges, are primitive in our syntax for the formulas of $n$PC.

3.1. Syntax of the $n$PC. Let $S_n$ denote the group of permutations of $\hat{n}$, ranged over by $\sigma, \pi, \rho, \ldots$, and let $V = \{X, Y, Z, X', \ldots\}$ be a countable set of propositional variables.

**Definition 5.** A formula of the $n$PC is either:

- a decorated propositional variable $X^\pi$, or
- one of the constants $e_1, \ldots, e_n$, or
- a compound formula $q(F, G_1, \ldots, G_n)$, where $F, G_1, \ldots, G_n$ are formulas.

We write $\mathcal{F}_n$ for the set of formulas.

The choice of decorating propositional variables by permutations deserves some explanations. As a matter of fact, $X^\pi$ will be proved to be logically equivalent to $q(X, e_{\pi(1)}, \ldots, e_{\pi(n)})$ (see Lemma 8) and we could have stipulated that atomic formulas are either propositional variables or constants. Nevertheless, the choice of decorating variables by permutations eases the task of defining an involutive form of negation.

$$1 - F = q(F, e_2, e_1),$$

where $q$ is the if-then-else, $e_1$ is 1 and $e_2$ is 0, whereas $F = q(F, e_1, e_2)$. Note also that in the instantiation of the rule (Sym) we have used the fact that $(F^{(12)})^{(12)} = F$, showed in Lemma 2.
Definition 6. Given $\rho \in S_n$ and a formula $F \in \mathcal{F}_n$, let $F^\rho$ be the formula inductively defined by:

$$
F^\rho = \begin{cases} 
X^{\rho \pi} & \text{if } F = X^\pi \\
e_{\rho(k)} & \text{if } F = e_k \\
q(F, G_1^\rho, \ldots, G_n^\rho) & \text{if } F = q(F, G_1, \ldots, G_n).
\end{cases}
$$

Lemma 1. For each $F \in \mathcal{F}_n$, $\pi, \rho \in S_n$: $(F^\pi)^\rho = F^{\rho \pi}$ and $F^{id} = F$.

Proof. Easy induction on $F$. □

The simplest non-trivial permutations are the exchanges, noted $(ij)$. Given $i, j \in \mathbb{n}$, the formula $F^{(ij)}$ is the negation of $F$ relatively to the dimensions $i$ and $j$. This kind of negation is involutive.

Lemma 2. For each $F \in \mathcal{F}_n$, $i, j \in \mathbb{n}$, we have that $F^{(ij)(ij)} = F$.

Proof. By Lemma 1 □

Thus, in $n$PC, the negations are strongly involutive in the sense that $F^{(ij)(ij)}$ and $F$ are the same formula.

It is worth noticing that, by defining the size of a formula as the maximal nesting level of compound formulas in it, $F$ and $F^{(ij)}$ have the same size, for all formulas. In an inductive proof, when dealing with $q(F, G_1, \ldots, G_n)$, the inductive hypothesis may be applied to $F, G_1, \ldots, G_n$, and to $F^{(ij)}, G_1^{(ij)}, \ldots, G_n^{(ij)}$ as well.

Contexts ranged over by $\Gamma, \Delta, \ldots$ are finite multisets of formulas, written as lists. As a matter of notation, if $\Gamma = F_1, \ldots, F_n$, $\Gamma^{(ij)}$ stands for $F_1^{(ij)}, \ldots, F_n^{(ij)}$. Also, in some premises of the deduction rules of Figure 1, $\{ \Gamma_i \vdash \Delta_i \}_{i \in I}$, $I \subseteq \mathbb{n}$, stands for a bunch of premises, one for each $i \in I$.

The notation $\Gamma \vdash_i \Delta$ means that the sequent $\Gamma \vdash \Delta$ is provable, using the rules of Figure 1.

The deduction rules of the systems may be justified using the notion of $n$-partition presented in Example 3.

If $G^1 = (G_1^1, \ldots, G_n^1), G^2, \ldots, G^r, F^1, \ldots F^s$ are $n$-partitions of a set $X$ and $1 \leq i \leq n$ then, intuitively, the sequent $G^1, \ldots, G^r \vdash_i F^1, \ldots F^s$ states that

$$
\bigcap_{l=1}^r G_i^l \subseteq \bigcup_{l=1}^s F_i^l
$$

This remark provides a handy guideline to verify the validity of the rules of figure 1 by considering that:

- $e_i$ stands for $n$-partition $(\emptyset, \ldots, \emptyset, X, \emptyset, \ldots, \emptyset)$, $X$ being at the $i$-th position.
- If $Y = (Y_1, \ldots, Y_n)$ is a $n$-partition and $\sigma$ is a permutation, then $Y^\sigma = (Y_{\sigma(1)}, \ldots, Y_{\sigma(n)})$. 

\[
\begin{array}{lll}
\Gamma \vdash \pi_i = \rho \pi_i & \quad & \pi_i \Delta \to \pi_i \Delta \quad \text{(Const)}
\end{array}
\]

\end{array}
\]

\[
\begin{array}{lll}
\Gamma, F, F \vdash \Delta \quad \Gamma, F \vdash F, \Delta \quad \Gamma, F \vdash F, \Delta \quad \text{(ConR)}
\end{array}
\]

**Figure 1.** The \( n \)-dimensional Propositional Calculus. Indexes \( i, j, k \) range over the set \( \hat{n} = \{1, \ldots, n\} \) of dimensions, \( \pi, \rho \in S_n \) and \( X \in V \). \( \Gamma, \Delta \) are finite multisets of formulas, represented as lists.

- The operator \( q_n \) acts on \( n \)-partitions as defined in Example 3.

Let us look now at rule \( \text{(Neg1)} \), for instance: the premise says that the intersection of the \( j \)-th components of the elements of \( \Gamma \) is included in the union of the \( i \)-th component of \( F \) and of the \( j \)-th components of the elements of \( \Delta \). Now, the \( i \)-th and the \( k \)-th component of \( F \) have an empty intersection, since \( i \neq k \). This ensures that that the intersection of the \( j \)-th components of the elements of \( \Gamma \) and of \( F^{(jk)} \) is included in the union of the \( j \)-th components of the elements of \( \Delta \), which is what the conclusion of the rule says. This kind of argument applies to all the rules of \( \text{nPC} \).

Some simple and expected properties of the system are given in the following lemma.

**Lemma 3.** For all \( F \in \mathcal{F}_n \) and for all \( i, j, k \in \hat{n} \):

(i) If \( i \neq j \), then \( \triangleright e_i \vdash_j \).

(ii) \( \triangleright F \vdash_i F \).

(iii) If \( i \neq k \), \( \triangleright F^{(ij)}, F^{(kj)} \vdash_j \).
Proof. (i)

\[
\begin{array}{c}
\vdash e_i \\
\text{(Const)} \\
\end{array}
\quad
\begin{array}{c}
\vdash e_i \\
\text{(Neg1)} \\
\end{array}
\]

where in rule \text{Neg1} \ k = j is chosen.\(\text{https://www.overleaf.com/project/621741b7a0a8f43be409b029}\)

(ii) By induction on the size of \(F\). The case of decorated variables is settled
by using axiom \text{Id}. Concerning constants, \(e_i \vdash e_i\) follows from \text{Const} and then
\text{WeakL}, while \(e_i \vdash e_i (i \neq j)\) follows from (i) and \text{WeakR}. If \(F = q(G, H_1, \ldots, H_n)\),
we apply \text{qL}, and have to prove \(\vdash G, H_{j(i)}(ij) \vdash F(ij)\), for \(1 \leq j \leq n\). Let us consider
first the case \(j = i\):

\[
\begin{array}{c}
\vdash H_i \\
\text{(Weak)} \\
\end{array}
\quad
\begin{array}{c}
\vdash G \\
\text{(Neg1)} \\
\end{array}
\]

\[
\begin{array}{c}
\vdash G \\
\text{(Weak+)} \\
\end{array}
\quad
\begin{array}{c}
\vdash H_{i}^{(ik)}, G \vdash G^{(ik)}, G \vdash G \\
\text{(qR)} \\
\end{array}
\]

only the \(i\)-th and \(k\)-th premisses are developed, for some \(k \neq i\). All the other
premisses are similar to the \(k\)-th. For increasing readability, several (left and
right) weakenings are merged in a \text{Weak+} (meta-)rule. Since \(\vdash H_i \vdash H_i\) and
\(\vdash G \vdash G\) follows from the inductive hypothesis, \(\vdash G, H_i \vdash F\) holds.

Let us consider now the case \(j \neq i\):

\[
\begin{array}{c}
\vdash H_j^{(ij)} \\
\text{(Weak+)} \\
\end{array}
\quad
\begin{array}{c}
\vdash G \\
\text{(Neg1)} \\
\end{array}
\]

\[
\begin{array}{c}
\vdash G \\
\text{(Weak+)} \\
\end{array}
\quad
\begin{array}{c}
\vdash H_{j}^{(ij)}, G \vdash G^{(jk)}, G \vdash H_{j}^{(ij)}, G \vdash H_{j}^{(ij)} \\
\text{(qR)} \\
\end{array}
\]

only the \(j\)-th and \(k\)-th premisses are developed, for some \(k \neq j\). All the other
premisses are similar to the \(k\)-th (in particular, the case \(k = i\)). The inductive
hypothesis allow to conclude that \(\vdash G, H_j^{(ij)} \vdash F(ij)\). Hence \(\vdash F \vdash F\) holds.

(iii)

\[
\begin{array}{c}
\vdash F \\
\text{(Neg1)} \\
\end{array}
\]

and we are done by (ii).

3.2. Semantics of the \(n\text{PC}\). \text{Environements}, ranged over by \(v, u, v_1, \ldots\) are
functions from the set \(V\) of propositional variables to the set \(\hat{n}\) of dimensions,
that should be considered here as generalized truth values.
Definition 7. $n$PC formulas are interpreted into $\hat{n}$ as follows:

- $[X^\pi]_v = \pi(v(X))$;
- $[e_i]_v = i$, for all $i \in \hat{n}$;
- $[q(F, G_1, \ldots, G_n)]_v = [G_1]_v$, where $i = [F]_v$.

In this setting the notions of tautology, satisfiability etc. are relative to dimensions. For instance, $F$ is an $i$-tautology if $[F]_v = i$, for all $v$.

The following generalisation of the notion of logical consequence is used in order to prove the soundness of the calculus.

Definition 8. Given two sequences of formulas $\Gamma, \Delta$, and $i \in \hat{n}$ we say that $\Delta$ is an $i$-logical consequence of $\Gamma$, written $\Gamma \models_i \Delta$, if for all environment $v$, if $[G]_v = i$ for all $G$ in $\Gamma$, then there exists $F$ in $\Delta$ such that $[F]_v = i$.

Lemma 4. For all $F$, $v$, $i$ and $j$, $[F]_v = i$ if and only if $[F^{(ij)}]_v = j$.

Proof. The proof is an easy induction on $F$. We describe the case $F = q(G, H_1, \ldots, H_n)$:

$$[q(G, H_1, \ldots, H_n)^{(ij)}]_v = [q(G, H_1^{(ij)}, \ldots, H_n^{(ij)})]_v$$

$$= ([G^{(ij)}]_{[F]_v}]_v$$

$$= j$$

$\Leftrightarrow$ by induction

$$[G[G_i]]_v = [q(G, H_1, \ldots, H_n)]_v$$

$$= i$$

$\square$

Proposition 3 (Soundness). For all $i \in \hat{n}$, $\Gamma$ and $\Delta$, if $\Gamma \vdash \Delta$ then $\Gamma \models_i \Delta$.

Proof. By induction on the proof of $\Gamma \vdash \Delta$. If the last rule is an instance of Const, Id, WeakL, WeakR, ConL, ConR or Cut, the conclusion is immediate. If it is Sym, Neg1, Neg2 or Neg3, use Lemma 4 and conclude.

Let us consider the case of qL, using the same notation as in Figure 1: given $v$ such that

- for all $R$ in $\Gamma$, $[R]_v = i$.
- $[q(F, G_1, \ldots, G_n)]_v = [G[F]_v]_v = i$.

we have to show that there exists $H$ in $\Delta$ such that $[H]_v = i$. Let $j = [F]_v$, and consider the $j$-th premise: $\Gamma^{(ij)}, F, G_j^{(ij)} \vdash_j \Delta^{(ij)}$. By Lemma 4 for all $R \in \Gamma$, we have $[R^{(ij)}]_v = j$, and $[G_j^{(ij)}]_v = ([G[F]_v]^{(ij)})_v = j$. Then there exists $H$ in $\Delta$ such that $[H^{(ij)}]_v = j$, by induction, and we conclude that $[H]_v = i$ by Lemma 4.

The case of qR is similar, and omitted. $\square$
4. Completeness

4.1. The Lindenbaum algebra $L_n$.

**Definition 9.** Two formulas $F$ and $G$ of $nPC$ are equivalent, written $F \sim G$, if, for all $i \in \hat{n}$, both $F \vdash_i G$ and $G \vdash_i F$ are provable.

**Lemma 5.** The relation $\sim$ is an equivalence relation on the set of formulas of $nPC$.

*Proof.* Symmetry is immediate. Reflexivity is proved in Lemma 3. Transitivity follows from the cut rule. □

**Lemma 6.** If $F_i \sim G_i$ for $0 \leq i \leq n$, then $q(F_0, \ldots, F_n) \sim q(G_0, \ldots, G_n)$.

*Proof.* The proof is similar to that of Lemma 3. In order to prove $q(F_0, \ldots, F_n) \vdash_i q(G_0, \ldots, G_n)$, we apply $qL$, and have to prove $F_0, \ldots, F_i, G_0, \ldots, G_i \vdash_i q(G_0, \ldots, G_n)$.

Let us consider first the case $i = j$:

$$
\begin{align*}
&\vdots \quad F_i \vdash_i G_i \\
& \frac{F_0, F_i, G_0 \vdash_i G_i}{F_0, F_i, G_0 \vdash_i q(G_0, \ldots, G_n)} (\text{Weak}^+) \\
& \vdots \quad F_0 \vdash_i G_0 (\text{Neg1}) \\
& \frac{F_0 \vdash_i (F_0^{(ik)}, G_0 \vdash_k (\text{Weak}^+))}{F_0, F_0^{(ik)}, G_0 \vdash_k G_k \vdash_k (\text{Weak}^+)} (qR)
\end{align*}
$$

only the $i$-th and $k$-th premisses are developed, for some $k \neq i$. All the other premisses are similar to the $k$-th. The conclusion follows from the hypothesis.

Let us consider now the case $i \neq j$:

$$
\begin{align*}
&\vdots \quad F_j \vdash_i G_j \\
& \frac{F_j \vdash_i G_j}{F_j^{(ij)}, G_0 \vdash_j G_j} (\text{Sym}) \\
& \frac{F_0, F_j^{(ij)}, G_0 \vdash_j G_j}{F_0, F_j^{(ij)} \vdash_j q(G_0, \ldots, G_n)} (\text{Weak}^+) \\
& \vdots \quad F_0 \vdash_j G_0 (\text{Neg1}) \\
& \frac{F_0 \vdash_j (F_0^{(jk)}, G_0 \vdash_k (\text{Weak}^+))}{F_0, F_0^{(jk)}, F_j^{(ij)(jk)}, G_0 \vdash_k G_k \vdash_k (\text{Weak}^+)} (qR)
\end{align*}
$$

only the $j$-th and $k$-th premisses are developed, for some $k \neq i$. All the other premisses are similar to the $k$-th. The conclusion follows from the hypothesis. □

The following lemma, generalising to all formulas the sequent calculus axiom $\text{Id}$, is needed to show that the equivalence classes of $\sim$ form an $nBA$.

**Lemma 7.** For all $i$, if $\pi, \rho \in \mathcal{S}_n$ are such that $\pi^{-1}(i) = \rho^{-1}(i)$, then for all formula $F$: $\vdash F^\pi \vdash_i F^\rho$.

*Proof.* By induction on $F$. If it is a decorated variable the proof is immediate by the axiom $\text{Id}$.
If $F = e_k$, then we have two cases. If $\pi(k) = i$, then $\rho(k) = i$ and $e_k^\pi = e_k^\rho = e_i$. We get $\vdash e_i \vdash e_j$ by $\text{Const}$ and $\text{WeakL}$. If $\pi(k) \neq i$, then we get $\vdash e_{\pi(k)} \vdash e_{\pi(k)}$ by Lemma 3(i) and $\text{WeakR}$.

If $F = q(G, H_1, \ldots, H_n)$, then we consider a proof branch for $1 \leq j \leq n$:

\[
\frac{\{G, H_k^{(j)\circ(i)\circ\pi}, G^{(jk)} \vdash H_j^{(j)\circ(i)\circ\pi}\}_{k \in \hat{n}}}{F^{(ij)\circ\pi}, G \vdash H_j^{(j)\circ\pi}} \quad (qL)
\]

\[
\frac{F^{\pi} \vdash F^{\rho}}{(qR)}
\]

Let us prove that the uppermost sequents are provable, for all $j$ and $k$. If $j \neq k$ then the sequent $G, G^{(jk)} \vdash_k$ follows from $G \vdash_k G$ using the rule $\text{Neg1}$. Otherwise, if $j = k$, the provability of the sequent $H_k^{(j)\circ(i)\circ\pi} \vdash_k H_j^{(j)\circ(i)\circ\pi}$ is given by the inductive hypothesis. □

**Lemma 8.** For each $H \in \mathcal{F}_n$ and $\pi \in \mathcal{S}_n$, $H^\pi \sim q(H, e_{\pi(1)}, \ldots, e_{\pi(n)})$.

**Proof.** Given $i$, let us begin by proving that $\vdash q(H, e_{\pi(1)}, \ldots, e_{\pi(n)}) \vdash_i H^\pi$:

\[
\frac{\{H, e_{\pi(j)}^{(ij)} \vdash_j H^{(ij)\circ\pi}\}_{j \in \hat{n}}}{q(H, e_{\pi(1)}, \ldots, e_{\pi(n)}) \vdash_i H^\pi} \quad (qL)
\]

We reason by case analysis on $j$: if $\pi(j) \neq i$, then $e_{\pi(j)}^{(ij)} = e_{(ij)\circ\pi(j)} \neq e_j$. Since the sequent $e_{\pi(j)}^{(ij)} \vdash_j$ is provable by Lemma 3(i), then by applying $\text{WeakR}$ and $\text{WeakL}$ we get $\vdash H, e_{\pi(j)}^{(ij)} \vdash_j H^{(ij)\circ\pi}$. If $\pi(j) = i$, then we apply Lemma 7 to prove $H \vdash_j H^{(ij)\circ\pi}$, because $((ij) \circ \pi)^{-1}(j) = id^{-1}(j)$. We obtain the conclusion $H, e_j \vdash_j H^{(ij)\circ\pi}$ by applying $\text{WeakL}$.

Concerning $\vdash H^\pi \vdash_i q(H, e_{\pi(1)}, \ldots, e_{\pi(n)})$ we apply $\text{qR}$:

\[
\frac{\{H^{(ij)\circ\pi}, H \vdash_j e_{\pi(j)}^{(ij)}\}_{j \in \hat{n}}}{H^\pi \vdash_i q(H, e_{\pi(1)}, \ldots, e_{\pi(n)})} \quad (qR)
\]

If $\pi(j) = i$, then $e_{\pi(j)}^{(ij)} = e_j$ and we are done by $\text{Const}$ and weakening. If $\pi(j) \neq i$, then $((ij) \circ \pi)(j) \neq j$. In this case, renaming $\sigma$ the permutation $(ij) \circ \pi$ and putting $r = \sigma(j)$, we proceed by applying $\text{Neg1}$ with $\Gamma := H, F := H^\sigma$ and $k := j$:

\[
\frac{H^{(jr)} \vdash_r H^{\sigma}}{H^\sigma, H \vdash_j e_{\pi(j)}^{(ij)}} \quad (\text{Neg1})
\]

\[
\frac{H^\sigma, H \vdash_j e_{\pi(j)}^{(ij)}}{H^\sigma, H \vdash_j e_{\pi(j)}^{(ij)}} \quad (\text{WeakR})
\]

Since $\sigma^{-1}(r) = j = (jr)^{-1}(r)$, the sequent $H^{(jr)} \vdash_r H^\sigma$ is provable by Lemma 7. □
Theorem 3. The quotient set $\mathcal{F}_n/\sim$ is the carrier set of a nBA, denoted by $L_n$, and called the Lindenbaum algebra of the $n$PC.

Proof. To increase readability, for $F \in \mathcal{F}_n$ we write $F$ instead of $[F]$. We now prove the identities characterising nBAs.

(B1):

$$
\frac{H_k^{(ik)} \vdash_k H_k^{(ik)}(\text{WeakL})}{e_k, H_k^{(ik)} \vdash_k H_k^{(ik)}(\text{WeakL})} \quad \left\{ \frac{e_k \vdash_j e_k, H_k^{(ij)} \vdash_j H_k^{(ij)}(\text{Weak}^+)}{j \in \hat{n} \setminus \{k\}} \right\}
q(e_k, H_1, \ldots, H_n) \vdash_i H_k
$$

(B2):

$$
\frac{R_{(ij)} \vdash_j R_{(ij)}(\text{WeakL})}{H, R_{(ij)} \vdash_j R_{(ij)}(\text{WeakL})} \quad \left\{ \frac{R_{(ij)} \vdash_j R_{(ij)}(\text{WeakL})}{H \vdash_j R_{(ij)}(\text{WeakL})} \right\}
q(H, R, \ldots, R) \vdash_i R
R \vdash_i q(H, R, \ldots, R)
$$

(B4):

$$
\frac{H \vdash_i H(\text{WeakL})}{H, e_i \vdash_i H(\text{WeakL})} \quad \left\{ \frac{e_i \vdash_j e_i, H^{(ij)} \vdash_j H^{(ij)}(\text{Weak}^+)}{j \in \hat{n} \setminus \{i\}} \right\}
q(H, e_1, \ldots, e_n) \vdash_i H
$$

Lemma $\exists(iii)$

$$
\frac{\vdash_i e_i(\text{WeakL})}{H, H \vdash_i e_i(\text{WeakL})} \quad \left\{ \frac{H^{(ij)}, H \vdash_j H^{(ij)}(\text{WeakR})}{H^{(ij)}, H \vdash_j e_i^{(ij)}(\text{WeakR})} \right\}
q(H, e_1, \ldots, e_n)
$$

(B3): We have to show that, for all $G, F_k^n$ ($1 \leq r \leq n$ and $0 \leq k \leq n$), the formulas

$$
H_1 = q(G, q(F_{0}^{1}, \ldots, F_{1}^{1}), \ldots, q(F_{0}^{n}, \ldots, F_{n}^{n}))
$$

and

$$
H_2 = q(q(G, F_{0}^{1}, \ldots, F_{0}^{n}), \ldots, q(G, F_{n}^{1}, \ldots, F_{n}^{n}))
$$

are equivalent. For all $i$, the proofs of $H_1 \vdash H_2$ and of $H_2 \vdash H_1$ are trees of branching factor $n$ and depth 5. Each leaf of those proof trees is identified by a sequence of 5 integers $j, k, l, h, m$ between 1 and $n$, its branch. We are going to construct one of such branches, and argue that the corresponding leaf is always
a provable sequent, by case analysis on the sequence of integers associated to it. Five different exchanges come into play in this derivation, that we rename for typographical reasons: \( \pi := (ij) \), \( \rho := (jk) \), \( \sigma := (kl) \), \( \tau := (lh) \), \( \psi := (hm) \). In the following proof the principal formula of each rule application is depicted in blue.

\[
\begin{align*}
G^\psi & \vdash_o \frac{F_0^\psi \delta_0^\sigma, F_1^\psi \delta_0^\sigma, G^\sigma, F_0^\rho \delta_0^\sigma, G \vdash_m F_m^\psi \delta_0^\sigma}{G^\psi, F_0^\rho \delta_0^\sigma, F_1^\rho \delta_0^\sigma, G \vdash_h q(G, F_j^\sigma \delta_0^\rho, \ldots, F_j^n \delta_0^\rho)} (qR) \\
G^\sigma & \vdash_l \frac{G^\sigma, F_0^\rho \delta_0^\sigma, q(G, F_0^\sigma \delta_0^\rho, \ldots, F_0^n \delta_0^\rho) \vdash q(G, F_j^\sigma \delta_0^\rho, \ldots, F_j^n \delta_0^\rho)}{q(G, F_0^\rho \delta_0^\sigma, \ldots, F_0^n \delta_0^\rho) \vdash q(G, F_j^\rho \delta_0^\rho, \ldots, F_j^n \delta_0^\rho)} (qL) \\
G, q & \vdash_l \frac{G, F_0^k \delta_0^\rho, \ldots, F_0^n \delta_0^\rho, q(G, F_0^\sigma \delta_0^\rho, \ldots, F_0^n \delta_0^\rho) \vdash q(G, F_j^\rho \delta_0^\rho, \ldots, F_j^n \delta_0^\rho), G \vdash \frac{F_j^\rho \delta_0^\rho}{F_j^\sigma \delta_0^\rho}}{H_1^l, q(G, F_0^\rho, \ldots, F_0^n) \vdash q(G, F_j^\rho, \ldots, F_j^n)} (qL) \\
& \vdash \frac{H_j^l, q(G, F_0^\rho, \ldots, F_0^n) \vdash q(G, F_j^\rho, \ldots, F_j^n)}{H_1^l \vdash H_2} (qR)
\end{align*}
\]

We are going to show that the uppermost sequent \( S \) is provable, by case analysis on \( j, k, l, h, m \). First of all, if \( h \neq m \), then \( G^{(hm)}, G \vdash m \) is provable by Lemma 3(iii) and \( S \) is provable by weakening. Hence we are left with the case \( h = m \); the uppermost sequent \( S \) becomes:

\[
G^\sigma, F_0^k \delta^\rho, F_1^l \delta^\rho, G, F_0^l \delta^\rho, G \vdash_h F_j^h \delta^\rho.
\]

\((k \neq h)\): The sequent \( G^\sigma, G \vdash_h \) is provable as follows:

\((l \neq h)\): Since in this case \((lh)^{-1}(l) = (\tau \circ \sigma)^{-1}(l)\), then we have:

\[
\begin{align*}
\text{Lemma 7} & \\
G^{(lh)} & \vdash \frac{G^\sigma}{G^\tau \sigma} (Neg1)
\end{align*}
\]

\((l = h)\): \( G^\sigma, G \vdash_l \) follows from Lemma 3(iii).

\((k = h)\): The uppermost sequent \( S \) becomes:

\[
G, F_0^k \delta^\rho, F_1^k \delta^{\rho \sigma}, G, F_0^\rho \delta^\sigma, G \vdash \frac{F_j^h \delta^\rho \sigma}{F_j^l \delta^\rho \sigma},
\]

because in the hypothesis \( \sigma = \tau \) and \( \sigma \circ \tau = \tau \circ \sigma = id \).

\((j \neq l)\): \( F_0^k \delta^\tau, F_0^k \delta^l \vdash_k \) is provable as follows:

\[
\begin{align*}
F_0^k(jk) & \circ (lk) \vdash_k F_0^k \circ_j \frac{F_0^k (lk)}{F_0^k (jk)} (Sym)
\end{align*}
\]

Now the proof of \( F_0^k(jk) \circ (lk), F_0^k \vdash_j \) is exactly like that of \( G^\sigma, G \vdash_h \) above.

\((j = l)\): Both side of the uppermost sequent contain \( F_1^k \delta^{\rho \sigma} \), and we are done.

The proof of \( H_2 \vdash_i H_1 \) is similar.
4.2. **Completeness of the nPC.** We are going to prove that if \( \Gamma \models_i F \) then \( \Gamma \vdash_i F \). To begin with, we define a multideal depending on \( \Gamma \) and \( i \). Remark that provability is invariant with respect to the Lindenbaum algebra. This means that if \( \triangleright \Gamma \vdash_i F \) and \( F \sim G \) then, by a simple application of rule \((\text{Cut})\), we get \( \triangleright \Gamma \vdash_i G \).

**Definition 10.** Given \( i \in \hat{n} \) and a set of formulas \( \Gamma \), let \( \mathcal{I}_j^{(\Gamma,i)} = \{ [F] : \triangleright \Gamma \vdash_i F^{(ij)} \} \), for \( j = 1, \ldots, n \).

**Lemma 9.** \( \mathcal{I}^{(\Gamma,i)} \) is a multideal of the Lindenbaum algebra of nPC.

**Proof.** In this proof we write \( I_j \) for \( \mathcal{I}_j^{(\Gamma,i)} \).

We show that \( (I_j)_{j \in \hat{n}} \) satisfies the conditions of Definition 4.

- \( e_j \in I_j \) is trivially true.
- If \( F_1, \ldots, F_n \in I_j \) then, for all \( G, q(G, F_1, \ldots, F_n) \in I_j \):

  \[
  \begin{align*}
  \Gamma \vdash I_k^{(ij)} & \quad (\text{Sym + Weak}) \\
  \Gamma^{(ik)}, G \vdash_k (F_k^{(ij)})^{(ik)} & \quad (qR) \\
  \end{align*}
  \]

- If \( F \in I_j \) and \( G \in I_k \) then \( q(G, H_1, \ldots, H_{k-1}, F, H_{k+1}, \ldots, H_n) \in I_j \), for all formulas \( H_1, \ldots, H_n \):

  \[
  \begin{align*}
  \Gamma \vdash q(G, H_1^{(ij)}, \ldots, H_{k-1}^{(ij)}, F^{(ij)}, H_{k+1}^{(ij)}, \ldots, H_n^{(ij)}) & \quad (qR) \\
  \end{align*}
  \]

  The rightmost antecedent follows from \( \Gamma \vdash_i F^{(ij)} \) by rules \((\text{Weak}) + (\text{Sym})\).

Concerning the leftmost antecedents, we show that they are provable for \( l \neq k \).

\[
\begin{align*}
\Gamma \vdash I_k^{(ij)} & \quad (\text{Sym + Weak}) \\
\Gamma^{(ik)}, G \vdash_k (F_k^{(ij)})^{(ik)} & \quad (qR) \\
\end{align*}
\]

Remark that all formulas of \( \Gamma \) belong to \( \mathcal{I}_i^{(\Gamma,i)} \), by Lemma 3.

Given an ultramultideal \( U = (U_1, \ldots, U_n) \), let \( v^U \) be the environment associating to the variable \( X \) the integer \( i \) such that \( X^{id} \in U_i \).

**Lemma 10.** For all formulas \( F \), \( [F]_{v^U} = i \) if and only if \( [F] \in U_i \).
Proof. Induction on formulas, using the fact that $X^ρ \sim q(X^{id}, e_ρ(1), \ldots, e_ρ(n))$. □

Proposition 4 (Completeness). If $Γ \models_i F$ then $Γ \vdash_i F$.

Proof. Let us suppose that $Γ \not\models_i F$, so that $F \notin I_{Γ,i}^{(Γ,i)}$. Since the multideal $I_{Γ,i}^{(Γ,i)}$ is the intersection of all the ultramultideals containing it, see Proposition 2 there exists an ultramultideal $U$ extending $I_{Γ,i}^{(Γ,i)}$ such that $Γ \subseteq I_{Γ,i}^{(Γ,i)} \subseteq U_i$ and $F \notin U_i$. Hence by Lemma 10 $[F]_U \neq i$ and for all $G \in Γ [G]_U = i$, proving that $Γ \not\models_i F$. □

Theorem 4. $Γ \models_i F$ iff $Γ \vdash_i F$.

Proof. By Propositions 3 and 4. □

5. The classical case

In this section, we compare the usual propositional calculus PC and the 2 dimensional propositional calculus 2PC. Formulas of PC are built with the constants 0,1, variables $X \in V$, and the connectives $\neg$, $\land$ and $\lor$. The sequent calculus is given in Figure 2. It is sound and complete: a sequent $Γ \vdash ∆$ is provable iff it is valid. We have chosen a formulation which is close to the nPC sequent calculus.
0° = e₂
1° = e₁
X° = X^{id}
(¬P)° = (P°)^{(12)}
(P ∧ Q)° = q(P°, Q°, e₂)
(P ∨ Q)° = q(P°, e₁, Q°)

<table>
<thead>
<tr>
<th>e° = 0</th>
<th>e° = 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>(X^{id})° = X</td>
<td>(X^{(12)})° = ¬X</td>
</tr>
<tr>
<td>q(F, G, H)° = (F° ∧ G°) ∨ (¬F° ∧ H°)</td>
<td></td>
</tr>
</tbody>
</table>

Figure 3. The translations.

In order to compare PC and 2PC, we provide in Figure 3 translations from PC formulas to 2PC formulas and conversely. As a matter of notation, P, Q, R denote formulas of PC, and F, G, H formulas of 2PC. Notice that, for n = 2 there exist two permutations of ˆn: the identity id and the exchange (12).

Γ° and Γ° denote the translations of sequences of formulas. We are going to show, in Corollary 2 that PC and 2PC are equivalent in the sense that ▷ Γ ⊢ Δ iff ▷ Γ° ⊢ 1Δ° and ▷ Γ ⊢ Δ iff ▷ Γ° ⊢ 1Δ°

Since both calculi are sound and complete with respect to suitable notions of validity of sequents, the easiest way to prove this equivalence is through the semantics.

Each environment v of 2PC may be seen as an environment of PC, and conversely, simply by exchanging the values 2 and 0. In the sequel, we will keep this implicit.

Proof. Both statement are proved by straightforward inductions, on F and P respectively.

Corollary 2. (1) Let Γ, Δ be sequences of 2PC formulas and Γ₁, Δ₁ sequences of PC formulas. Then ▷ Γ ⊢ 1Δ iff ▷ Γ° ⊢ 1Δ°, and Γ₁ ⊢ Δ₁ iff Γ°₁ ⊢ 1Δ°₁.

(2) Let Γ, Δ be sequences of 2PC formulas and Γ₁, Δ₁ sequences of PC formulas. Then ▷ Γ ⊢ 1Δ iff ▷ Γ° ⊢ 1Δ°, and ▷ Γ₁ ⊢ Δ₁ iff ▷ Γ°₁ ⊢ 1Δ°₁.

Proof. (1) follows from Lemma 11

(2) Since the calculus of Figure 2 is sound and complete for the Propositional Calculus, the result follows from Theorem 4 and Corollary 2.1.

We conclude this section by presenting two examples of simulations of PC by 2PC and vice-versa, at the level of proofs of the sequent calculus.

Example 4. Consider the following instance of the the rule ∧R of PC:

\[
\frac{X \vdash Y}{X \wedge Y} \quad (\land R)
\]
where $X$ and $Y$ are propositional variables. The 2PC formula $(X \land Y)^o = q(X^{id}, Y^{id}, e_2)$ may be proved as follows, under the hypothesis $\vdash X^{id}$ and $\vdash Y^{id}$.

\[
\begin{array}{c}
\vdash Y^{id} \\
\hline
X^{id} \vdash Y^{id} \\
\end{array}
\] (WeakL) \hspace{1cm}
\begin{array}{c}
\vdash X^{id} \\
\hline
X^{id} \vdash 2 \quad (\text{Neg1})
\end{array}

\begin{array}{c}
\vdash 1 \\
\hline
\end{array}
\begin{array}{c}
\vdash X^{id} \\
\hline
\vdash q(X^{id}, Y^{id}, e_2) \\
\end{array}
\hspace{1cm} (qR)

• The left rule for $\land$

\[
\begin{array}{c}
X, Y \vdash \\
\hline
X \land Y \vdash \\
\end{array}
\] (\land L)

may be translated as follows:

\[
\begin{array}{c}
\vdash 1 \\
\hline
\vdash e_1 \\
\end{array}
\begin{array}{c}
\vdash e_1 \\
\hline
\vdash X^{id}, e_1 \vdash \\
\end{array}
\begin{array}{c}
\vdash 2 \\
\hline
\vdash q(X^{id}, Y^{id}, e_2) \\
\end{array}
\hspace{1cm} (qL)

In order to show an example of simulation in the opposite direction, the following lemma is useful.

**Lemma 12.** If $\Gamma \vdash 2 \Delta$, then $\Gamma^{(12)} \vdash \Delta^{(12)}$.

**Proof.** From $\Gamma \vdash 2 \Delta$ we obtain $\Gamma^{(12)} \vdash 1 \Delta^{(12)}$ by applying rule Sym. Then we conclude by Corollary 2.2. □

**Example 5.**

• Consider the following instance of the rule $qR$ of 2PC:

\[
\begin{array}{c}
\vdash 1 \\
\hline
\vdash X^{id} \\
\vdash Y^{id} \\
\hline
\vdash q(X^{id}, Y^{id}, Z^{id}) \\
\end{array}
\] (qR)

The PC formula $q(X^{id}, Y^{id}, Z^{id})^o = (X \land Y) \lor (\neg X \land Z)$ may be proved as follows, under the hypothesis $X \vdash Y$ and $\neg X \vdash Z$:

\[
\begin{array}{c}
\vdash X \\
\hline
\vdash Y \\
\end{array}
\] (Id)

\[
\begin{array}{c}
\vdash X \land Y \\
\hline
\end{array}
\] (\land R)

\[
\begin{array}{c}
\vdash X \lor \neg X \\
\hline
\end{array}
\] (\lor L)

\[
\begin{array}{c}
\vdash \neg X \\
\hline
\end{array}
\] (\neg R)

\[
\begin{array}{c}
\vdash \neg X \\
\hline
\end{array}
\] (\lor R)

\[
\begin{array}{c}
\vdash X \lor \neg X \\
\hline
\end{array}
\] (Cut)

\[
\begin{array}{c}
\vdash X \\
\hline
\end{array}
\] (Id)

\[
\begin{array}{c}
\vdash \neg X \\
\hline
\end{array}
\] (\neg R)

\[
\begin{array}{c}
\vdash \neg X \\
\hline
\end{array}
\] (\lor R)

\[
\begin{array}{c}
\vdash X \lor \neg X \\
\hline
\end{array}
\] (Cut)
• The rule \((qL)\):

\[
\frac{X^{id}, Y^{id} \vdash 1}{q(X^{id}, Y^{id}, Z^{id}) \vdash 1} (qL)
\]

may be translated as follows:

\[
\frac{X, Y \vdash}{X \wedge Y \vdash (\wedge L)} \quad \frac{\neg X, Z \vdash}{\neg X \wedge Z \vdash (\wedge L)} \quad \frac{(X \wedge Y) \vee (\neg X \wedge Z) \vdash}{(\vee L)}
\]

6. Conclusion

The sequent calculus introduced in this paper is sound and complete with respect to the canonical notion of semantic validity of \(n\)-dimensional propositional formulas. The main features of this sequent calculus are: (i) any truth-value \(e_i\) has its own turnstyle \(\vdash_i\), and (ii) formulas (viz. propositional variables) are decorated with elements of the symmetric group \(S_n\). This latter feature entails a strong form of involution: \(F\) and its double-negation are the same formula. Concerning (i), in the binary case, the proofs of \(\vdash_2 F\) should be considered as refutations of \(F\).

The proof of completeness relies on the presence of the cut rule in the system. The study of the cut elimination procedure, and the introduction of a term-language for the proofs of \(n\)-PC sequents are left as further work.
