ABSTRACT. We study the number of degree $n$ number fields with discriminant bounded by $X$. In this article, we improve an upper bound due to Schmidt on the number of such fields that was previously the best known upper bound for $6 \leq n \leq 94$.

1. INTRODUCTION AND OUTLINE OF PAPER

Let $N_n(X) := \# \{K/Q : [K : Q] = n, \text{Disc}(K) \leq X \}$ count the number of degree $n$ number fields over $Q$ with bounded discriminant of size $X$. We consider all extensions as being inside a fixed algebraic closure $\overline{Q}$ of $Q$. The Hermite-Minkowski theorem states that $N_n(X)$ is finite and bounded by $O_n(X^n)$. It is conjectured that the actual sharp upper bound is $O_n(X)$; thus improvements to the Hermite-Minkowski theorem have attracted a lot of attention.

For $n \leq 5$, precise asymptotic formulas for $N_n(X)$ are known [DH69, CDyDO02, Bha05, Bha10]. For $n \geq 95$, the best bound is due to Lemke Oliver and Thorne [LOT20], who show that $N_n(X) \ll_n X^{c(\log n)^2}$ for all $n \geq 6$, where $c \leq 1.564$ is an explicitly computable constant for each $n$. In the middle range $6 \leq n \leq 94$, the best bound is due to Schmidt [Sch95], who gave one of the first substantial bounds by proving that $N_n(X) \ll X^{(n+2)/4}$ for all $n \geq 2$.

Our main theorem gives a general improvement over the Schmidt bound.

**Theorem 1.1.** For each $n \geq 6$ and every $\epsilon > 0$, we have $N_n(X) \ll_{n, \epsilon} X^{\frac{n+2}{4} - \frac{1}{2n-2} + \epsilon}$.

We do not expect that the saving $\frac{1}{2n-2}$ is optimal for our method, but to extract a further saving from the work below would take a little care. In fact, our work is inspired by work of Bhargava, Shankar, and Wang [BSW22], and simultaneously with our work, an improvement of (essentially) $\frac{1}{2n-2}$ over Schmidt’s bound was independently obtained by the same authors in [BSW]. Their work bears some similarity with our approach, but also differs greatly in other ways. Therefore, we expedite some pieces of our approach, while focusing on other pieces where our techniques are different and which we expect to have other applications.

In §2, we summarize Schmidt’s approach of estimating $N_n(X)$ by counting monic polynomials $f(x) = x^n + c_1 x^{n-1} + \cdots + c_n$ where each $c_i$ is bounded by $O(X^{\frac{1}{2n-2}})$. We slightly restructure Schmidt’s method in order to not restrict to polynomials of trace 0. To improve upon Schmidt’s bound, we separately count polynomials with “particularly small” discriminants and polynomials with “particularly squarefull” discriminants in comparison to the discriminants of the fields they cut out. Our method is easier to describe in the context of Schmidt’s method, thus we defer further description until §2.1. We note loosely, though, that the polynomials with “particularly small” discriminant are considered in §3 and that the polynomials with “particularly squarefull” discriminant are considered in §5 and §6.

It is in §4 and §5 that our approach differs most substantially from [BSW22] and [BSW]. In §4, which we regard as our most novel, we study the nonarchimedean Fourier transform of polynomials whose discriminant is divisible by a large power of a prime. We expect that such Fourier transforms may play a role in other problems beyond that considered in Theorem 1.1, for example perhaps in generalizing the ideas from [ST20]. We use the considerations of §4 to show in §5 bounds for polynomials whose discriminants are “powerful”, that is they admit prime factors to large powers.
Finally, in §6, we study polynomials whose discriminants have a large factor that is not powerful, incorporating the framework of [BSW22]. The specific prime factorization of the large factor dividing the polynomial discriminant determines which polynomials are treated using §5 or §6, and is described in the next section.

ACKNOWLEDGEMENTS

This collaboration arose initially from an AIM workshop on Fourier Analysis, Arithmetic Statistics, and Discrete Restriction organized by two of the authors (T.A. and F.T.) and Trevor Wooley. The authors thank AIM for a very supportive working environment.

The authors thank Manjul Bhargava, Arul Shankar, and Jerry Wang for sharing a preprint version of their manuscript [BSW], and for many useful conversations.

FT is supported by NSF Grant No. DMS-2101874 and a Simons Collaboration Grant (No. 586594). RZ is supported by NSF DMS-1856541 and NSF DMS-2207281.

2. OUTLINE OF APPROACH

Let $\mathcal{F}_n(X)$ denote the set of fields $K/\mathbb{Q}$ with degree $n$ and discriminant satisfying $|\text{Disc}(K)| \leq X$. The Schmidt bound [Sch95] asserts that $\#\mathcal{F}_n(X) \ll_n X^{\frac{n+2}{4}}$. The key to Schmidt’s approach is the following.

**Lemma 2.1.** Let $K \in \mathcal{F}_n(X)$ and assume $K$ is primitive, i.e. that it has no proper nontrivial subfields. Then there is a monic polynomial $f(x) \in \mathbb{Z}[x]$ with trace 0, i.e. $f(x) = x^n + c_2 x^{n-2} + \cdots + c_n$, for which $K \simeq \mathbb{Q}[x]/(f(x))$ and where each $c_i$ satisfies $|c_i| \ll_n X^{\frac{n-2}{4}}$.

**Proof.** In the Minkowski embedding, the trace 0 elements of $\mathcal{O}_K$ form a rank $n - 1$ lattice with covolume $\cong_n |\text{Disc}(K)|^{1/2}$. The $n - 1$ Minkowski minima for this lattice satisfy $\lambda_1 \cdots \lambda_{n-1} \simeq |\text{Disc}(K)|^{1/2}$, so $\lambda_1 \ll_n |\text{Disc}(K)|^{1/2(n-1)}$. In particular, there is a non-zero element $\alpha \in \mathcal{O}_K$ with trace 0 whose height is $O_n(|\text{Disc}(K)|^{\frac{1}{2(n-1)}})$. Since $\alpha$ has trace 0 and $\alpha \neq 0$, it follows that $\alpha \not\in \mathbb{Q}$. By our assumption that $K$ admits no interesting subfields, it follows that $\mathbb{Q}(\alpha) = K$. The minimal polynomial of $\alpha$ then satisfies the conclusion of the lemma. \qed

There are $O_n(X^{\frac{n+2}{4}})$ polynomials of the type produced in Lemma 2.1. It thus follows that the number of primitive fields contained in $\mathcal{F}_n(X)$ is also $O_n(X^{\frac{n+2}{4}})$.

**Remark 2.2.** To get a bound on non-primitive fields too, Schmidt (essentially) uses this argument, but over a moving subfield. His bound actually improves for the number of imprimitive fields: if $d_{\text{max}}$ is the largest proper divisor of $n$, his bound on imprimitive fields in $\mathcal{F}_n(X)$ is $X^{\frac{d_{\text{max}}+2}{4}}$. This is smaller than the bound claimed in Theorem 1.1, so it suffices to prove the claimed bound holds for the set $\mathcal{F}_n^{\text{prim}}(X)$ of primitive field extensions.

It is possible to rework Schmidt’s argument very slightly in that way that makes it marginally more convenient to invoke the results of the earlier work of Bhargava, Shankar, and Wang [BSW22]. First, we consider polynomials without trace 0.

**Lemma 2.3.** Let $n \geq 2$. There is a constant $C_n > 0$ such that each field $K \in \mathcal{F}_n^{\text{prim}}(X)$ is cut out by $\gg_n X^{\frac{n-1}{2}}$ polynomials $f(x) \in \mathbb{Z}[x]$ of the form $f(x) = x^n + c_1 x^{n-1} + \cdots + c_n$, where each $c_i$ satisfies $|c_i| \leq C_n X^{\frac{n-2}{4}}$.

**Proof.** Let $H_0$ denote the maximum over $K \in \mathcal{F}_n^{\text{prim}}(X)$ of the minimal height of an element $\alpha \in \mathcal{O}_K$ with trace 0. By the proof of Lemma 2.1, we have $H_0 \ll_n X^{\frac{1}{2(n-1)}}$. In each $K \in \mathcal{F}_n^{\text{prim}}(X)$,
consider the elements of height at most $2H_0$. There are at least $H_0$ such elements, corresponding to the translates $\alpha + k$ for $|k| \leq H_0$, $k \in \mathbb{Z}$. The minimal polynomial $m(x) = x^n + c_1x^{n-1} + \cdots + c_n$ of such an element satisfies $|c_i| \ll_n H_0^i$, and the result follows.

For an admissible choice of $C_n$ in Lemma 2.3, set $H := C_n X^{1/2-\varepsilon}$. We refer to the polynomials of the type considered in Lemma 2.3, i.e. where the coefficients satisfy $|c_i| \leq H^i$, as having height $H$. There are $O_n(H^{n^2-n^2})$ polynomials of of height $H$, with each primitive field cut out by at least $\gg_n H$ different polynomials. Dividing by this minimum multiplicity, we find that there must be no more than $O_n(H^{n^2-n^2}) = O_n(X^{n^2-n^2})$ different fields produced, again recovering Schmidt’s bound.

Remark 2.4. The argument of Lemma 2.3 is a bit ad hoc, but its conclusion is likely close to optimal, apart from constants depending on $n$. For “typical” fields $K \in \mathcal{F}_n(X)$, we should expect the multiplicity with which $K$ is cut out to be $\asymp_n H^n/|\text{Disc}(K)|$. If $H = X^{1/2-\varepsilon} \approx |\text{Disc}(K)|^{1/2-\varepsilon}$, this expected multiplicity is about $H$. The proof of Lemma 2.3 thus doesn’t lose much, and its proof will be convenient in the next section.

2.1. Strategy and Proof of Main Theorem. While Lemmas 2.1 and 2.3 guarantee that each field $K \in \mathcal{F}_n^{\text{prim}}(X)$ is cut out by a polynomial of height $H \ll_n X^{1/2-\varepsilon}$, it is not the case that every such polynomial cuts out a field of discriminant at most $X$. In particular, for “typical” $f(x)$ of height $H$, we have $\text{disc}(f) \approx H^{n^2-n} = X^{n^2/2}$, and this is typically also the order of the discriminant of the field cut out by $f$. We should thus expect the relevant polynomials attached to $K \in \mathcal{F}_n^{\text{prim}}(X)$ to be exceptional in one of two ways: either the discriminant of $f$ is unusually small, or the discriminant of the field cut out by $f$ is much smaller than the discriminant of $f$. In the latter case, the ratio of the two discriminants is the square of the index $[\mathcal{O}_K : \mathbb{Z}[\alpha]]$ where $\alpha$ is a root of $f$: we call this integer the index of the polynomial $f$, denoted $\text{index}(f)$.

The condition that the discriminant is small is global, while the condition that the index is large is local. However, since both conditions are preserved under translation, it follows from the proof of Lemma 2.3 that each $K \in \mathcal{F}_n^{\text{prim}}(X)$ will still be cut out by $\gg_n H$ of these exceptional polynomials. Thus, our main task is to bound the number of exceptional polynomials.

Proof of Theorem 1.1. We now describe the proof of our main theorem more concretely.

By Lemma 2.3, to bound $K \in \mathcal{F}_n^{\text{prim}}(X)$ it suffices to bound the number of polynomials $f$ with height up to $H \asymp_n X^{1/2-\varepsilon}$ that cut out a field with discriminant $X \asymp_n H^{2n-2}$, where each field is counted with multiplicity of order at least $H$.

In Section 3, we prove the following corollary, bounding the the number of polynomials with small discriminant.

Corollary 2.5. Let $n \geq 3$ and let $H$ be sufficiently large in terms of $n$. The number of polynomials $f(x) \in \mathbb{Z}[x]$ of the form $f(x) = x^n + c_1x^{n-1} + \cdots + c_n$ with $|c_i| \leq H^i$ and $|\text{disc}(f)| \leq H^{n^2-n^2}$ is $O_n(H^{n^2-n-1})$.

If $f(x)$ is irreducible and cuts out the field $K$, then the discriminants of $f$ and $K$ are related through the equation $\text{disc}(f) = \text{Disc}(K)[\mathcal{O}_K : \mathbb{Z}[\alpha]]^2$, where $\alpha$ is a root of $f$ over $K$. We refer to the index $[\mathcal{O}_K : \mathbb{Z}[\alpha]]$ as the index of $f$, which we denote by $\text{index}(f)$. Corollary 2.5 implies that with at most $O_n(H^{n^2-n-1})$ exceptions,

$$\text{index}(f)^2 \cdot \text{Disc}(K) = \text{disc}(f) \geq H^{n^2-n-2}.$$

As $\text{Disc}(K) \leq X \asymp_n H^{2(n-1)}$, each of these polynomials has index bounded by

$$\text{index}(f) \gg_n H^{n^2-n^2-(n-1)} = H^{n(n-3)/2}.$$  (2.1)
Thus each of these polynomials has discriminant divisible by a large square. To bound the number of such polynomials, we consider two subcases: when the radical of index\((f)\) is small or large. (Recall that the radical of an integer is the product of its prime divisors.) In Section 5, we prove the following bound on the number of polynomials with large index, but small index radical.

**Theorem 2.6.** Let \(n \geq 6\) and fix any \(\epsilon > 0\). Then for any \(H \geq 1\), the number of polynomials \(f(x) \in \mathbb{Z}[x]\) of degree \(n\) and height \(H\) for which \(\text{rad} (\text{index}(f)) < H^{1-\epsilon}\) but \(\text{index}(f) > H^{\frac{n(n-3)}{2n}}\) is \(O_{n,\epsilon}\left(H^{\frac{n^2+n}{2} - \frac{1}{2}+\epsilon} + H^{\frac{n^2+n}{2} - \frac{1}{2}+3+\epsilon}\right)\).

And in Section 6, we bound the number of polynomials with large index radical.

**Theorem 2.7.** For any \(n \geq 3\), any \(H \geq 1\), any \(\epsilon > 0\), and any \(M \geq 1\), the number of polynomials \(f\) of degree \(n\), height \(H\), and where \(m^2 \mid \text{disc} f\) for some squarefree \(m \geq M\) is
\[
O_{n,\epsilon}\left(H^{\frac{n^2+n}{2}} + H^{\frac{n^2+n}{2} - \frac{1}{2}+\epsilon}\right).
\]

Theorem 2.6 implies that the number of polynomials of height \(H\), index bounded below by (2.1), and with \(\text{rad} (\text{index}(f)) < H^{1-\epsilon}\) is \(O_{n,\epsilon}(H^{\frac{n^2+n}{2} - \frac{1}{2}+\epsilon})\). All remaining uncounted polynomials have \(\text{rad} (\text{index}(f)) \geq H^{1-\epsilon}\), and thus have a squarefree divisor \(m\) of size at least \(H^{1-\epsilon}\) such that \(m^2 \mid \text{disc}(f)\). Taking \(M = H^{1-\epsilon}\) in Theorem 2.7 shows that there are at most \(H^{\frac{n^2+n}{2} - \frac{1}{2}+\epsilon}\) such polynomials.

Combining these bounds, we find that
\[
H \cdot \# F_{\text{prim}}^n (X) \ll_{n,\epsilon} H^{\frac{n^2+n}{2} - \frac{1}{2}+\epsilon},
\]
which completes the proof of Theorem 1.1 using \(H \asymp_n X^{\frac{1}{2n-2}}\).

3. The Density of Polynomials with Small Discriminant

We begin by proving the following proposition on the density of polynomials over some completion \(\mathbb{Q}_v\) of \(\mathbb{Q}\) with small discriminant. This result in the case that \(\mathbb{Q}_v = \mathbb{R}\) will be the key ingredient in the proof of Corollary 2.5, and the ideas behind the proof in the case that \(\mathbb{Q}_v\) is non-archimedean will be the key ingredient in the proof of Theorem 2.6.

**Proposition 3.1.** Let \(n \geq 2\) and let \(\mathbb{Q}_v\) be a completion of \(\mathbb{Q}\). Let \(\cdot | v\) be the associated absolute value and let \(\mu_v\) be the associated Haar measure on \(\mathbb{Q}_v\), normalized in the case that \(v\) is finite so that the total measure of \(\mathbb{Z}_v\) is 1 and so that \(\mu_v\) agrees with usual Lebesgue measure in the case that \(v\) is infinite. For \(c \in \mathbb{Q}_v^n\), let \(f_c(x) := x^n + c_1 x^{n-1} + \cdots + c_n\).

Then for any \(\delta \in (0,1)\), there holds
\[
\nu(\{c \in \mathbb{Q}_v^n : |c_i|_v \leq 1 \text{ for all } i \text{ and } |\text{disc}(f_c(x))|_v \leq \delta\}) \asymp_n \delta^{\frac{1}{2}+\frac{1}{n}}, \tag{3.1}
\]
where \(\nu\) denotes the product measure on \(\mathbb{Q}_v^n\).

**Proof.** Let \(1_\delta(f)\) be the characteristic function for the set of polynomials where \(|\text{Disc}(f)|_v \leq \delta\).

We start by applying a change of variables from Shankar–Tsimmerman [ST20, Lemma 2.2]. To describe this, we first fix some notation. Any \(n\)-dimensional étale algebra \(K_v/\mathbb{Q}_v\) may be expressed as a direct sum of field extensions of \(\mathbb{Q}_v\). If \(v\) is finite, let \(\mathcal{O}_K \subseteq K_v\) be the integral elements of \(K_v\), and let \(\mu\) denote Haar measure on \(\mathcal{O}_K\), normalized so that \(\mu(\mathcal{O}_K) = 1\). In the case that \(v\) is infinite, let \(\mathcal{O}_K\) be the compact region containing all the roots of polynomials \(f_c\) with \(|c_i|_v \leq 1\) such that \(\mathbb{R}[x]/f_c(x) \simeq K_v\), and let \(\mu\) denote the standard Euclidean/Lebesgue measure on \(\mathcal{O}_K\). Then
applying the change of variables from Shankar–Tsimerman, we find
\[
\nu(\{ c \in \mathbb{Q}_v^n \mid |c_i|_v \leq 1 \text{ for all } i \text{ and } |\text{disc}(f_c(x))|_v \leq \delta \})
\]
\[
= \sum_{[K_v : \mathbb{Q}_v]=n} \frac{|\text{Disc}(K_v)|^{1/2}}{|\text{Aut}(K_v)|} \int_{O_{K_v}} |\text{Disc}(f_\alpha)|^{1/2} \mathbf{1}_\delta(f_\alpha) \, d\mu(\alpha)
\]
\[
\leq \delta^{1/2} \sum_{[K_v : \mathbb{Q}_v]=n} \frac{|\text{Disc}(K_v)|^{1/2}}{|\text{Aut}(K_v)|} \int_{O_{K_v}} \mathbf{1}_\delta(f_\alpha) \, d\mu(\alpha),
\]
where \( f_\alpha \) denotes the characteristic polynomial of \( \alpha \), and where, in the inequality in the second line, we used the bound \(|\text{Disc}(\alpha)|_v \leq \delta\), valid for any \( \alpha \) for which \( \mathbf{1}_\delta(f_\alpha) \neq 0 \). Note that we have used the fact that the discriminant of the characteristic polynomial \( f_\alpha \) is bounded above by the discriminant of the minimal polynomial \( \alpha \).

We now estimate the integral, beginning with the where case \( K_v \cong \mathbb{Q}_v^n \) is the totally split algebra. In this case, \(|\text{Disc}(\alpha)|_v = \prod_{i<j} |\alpha_i - \alpha_j|_v^2\). Consequently, for any point in the support of \( \mathbf{1}_\delta \), we have
\[
\prod_{i=1}^{n} \prod_{j \neq i} |\alpha_i - \alpha_j|_v \leq \delta.
\]
The pigeonhole principle then implies that there must be some \( i \) for which
\[
\prod_{j \neq i} |\alpha_i - \alpha_j|_v \leq \delta^{1/n}.
\]
If we let \( \alpha_j' = \alpha_i - \alpha_j \) for each \( j \neq i \), it thus follows that \( \prod_{j \neq i} |\alpha_j'|_v \leq \delta^{1/n} \). Since \( O_{K_v} \) is compact, the measure of points satisfying this condition is \( O_n(\delta^{1/n}) \), independent of \( \alpha_i \). We therefore conclude in this case that
\[
\int_{O_{K_v}} \mathbf{1}_\delta(f_\alpha) \, d\mu(\alpha) \ll_{n} \delta^{\frac{1}{n}}.
\]
Moreover, letting \( \alpha_i \) be arbitrary and varying over \( \alpha_j \) for which \(|\alpha_i - \alpha_j|_v \leq \delta^{1/(n-1)}\) shows that an asymptotic lower bound of the same order must also hold.

We now turn to the case that \( K_v \) is not the totally split algebra. The idea in this case is substantially the same, but requires further notation. We may write \( K_v = \mathbb{Q}_v \oplus F_{i=1}^{r} F_i \) where each \( F_i \) is a field extension of \( \mathbb{Q}_v \) with degree \( n_i := [F_i : \mathbb{Q}_v] \), say, and where \( n_1 + \cdots + n_r = n \). Thus, to any \( \alpha \in O_{K_v} \), we have an associated \( r \)-tuple \((\alpha_1, \ldots, \alpha_r) \in \mathbb{Q}_v \oplus F_{i=1}^{r} O_{F_i} \). To such an \( \alpha \), we may associate the \( n \) roots \( \lambda_1, \ldots, \lambda_n \), where \( \lambda_1, \ldots, \lambda_{n_i} \) denote the conjugates of \( \alpha_1 \) under the action of \( \text{Gal}(\overline{F}_1/\mathbb{Q}_p) \), \( \lambda_{n_1+1}, \ldots, \lambda_{n_1+n_2} \) denote the conjugates of \( \alpha_2 \) under \( \text{Gal}(\overline{F}_2/\mathbb{Q}_p) \), etc. Thus, the characteristic polynomial of \( \alpha \) is simply the product \( \prod_{i=1}^{n} (x - \lambda_i) \). In the totally split case above, we have simply that \( \lambda_i = \alpha_i \) for each \( i \leq n \), but this is not the case in general.

We now coordinatize by fixing an integral basis for each \( O_{F_i} \), say \( \omega_{i,1}, \ldots, \omega_{i,n_i} \). For \( \mathbf{a} \in \mathbb{Z}_p^n \), we then let \( \alpha_1 = a_{1,1}\omega_{1,1} + \cdots + a_{1,n_1} \omega_{1,n_1}, \alpha_2 = a_{n_1+1}\omega_{2,1} + \cdots + a_{n_1+n_2} \omega_{2,n_2}, \) etc. So doing, we note that the linear transformation determining \( \mathbf{a} = (\lambda_1, \ldots, \lambda_n) \) from \( \mathbf{a} \) is a block diagonal matrix \( M_{K_v} \) whose determinant satisfies \(|\det M_{K_v}|_p = |\text{Disc}(K_v)|_p^{1/2}\). Now, the discriminant \( \text{Disc}(\alpha) \) satisfies
\[
|\text{Disc}(\alpha)|_v = \prod_{i=1}^{n} \prod_{j \neq i} |\lambda_i - \lambda_j|_v.
\]
Proceeding as in the totally split case, we conclude that for \( \alpha \) in the support of \( \mathbf{1}_\delta \), there must be some \( i \) for which
\[
\prod_{j \neq i} |\lambda_i - \lambda_j|_v \leq \delta^{\frac{1}{n}}.
\]
Accounting for the determinant of the matrix \( M_K \), sending the coordinates \( \mathbf{a} \) to the roots \( \lambda = (\lambda_1, \ldots, \lambda_n) \), we conclude that
\[
\int_{\mathcal{O}_K} 1_\delta(f_{\alpha}) \, d\mu(\alpha) \ll_n |\text{Disc}(K_v)|^{-1/2} \delta^{\frac{1}{n}}.
\]

We therefore find that
\[
\delta^{1/2} \sum_{[K_v:Q_v]=n} \frac{|\text{Disc}(K_v)|^{1/2}}{|\text{Aut}(K_v)|} \int_{\mathcal{O}_K} 1_\delta(f_{\alpha}) \, d\mu(\alpha) \ll_n \delta^{\frac{1}{2} + \frac{1}{n}} \sum_{[K_v:Q_v]=n} \frac{1}{|\text{Aut}(K_v)|} \ll_n \delta^{\frac{1}{2} + \frac{1}{n}},
\]
since the summation may be bounded in terms of the number of étale algebras of degree \( n \), which in turn may be bounded solely in terms of \( n \). \hfill \square

We now use Proposition 3.1 to bound the number of integral polynomials with small archimedean discriminant.

**Lemma 3.2.** Let \( n \geq 3 \), \( Y \geq 1 \), and \( H \) sufficiently large in terms of \( n \). Then the number of polynomials \( f(x) \in \mathbb{Z}[x] \) of the form \( f(x) = x^n + c_1 x^{n-1} + \cdots + c_n \) with \( |c_i| \leq H^2 \) and \( \text{Disc}(f) \leq H^{n^2-n}/Y \) is \( O_n(H^{\frac{n^2}{2}}/Y^{\frac{1}{2} + \frac{1}{n}} + H^{\frac{n^2-n}{2}}) \).

The key idea behind Lemma 3.2 is that the coefficients of the polynomials \( f(x) \) with small discriminant must lie in a compact region in \( \mathbb{R}^n \) with small volume, and thus we should expect there to be relatively few polynomials whose coefficients lie in this region. This is made rigorous by means of the Lipschitz principle from [Dav51]:

**Lemma 3.3** (Davenport). If \( \Omega \subseteq \mathbb{R}^n \) is a compact semialgebraic region (i.e., cut out by algebraic inequalities), then the number of lattice points in the intersection satisfies the bound
\[
\mathbb{Z}^n \cap \Omega = \text{vol}(\Omega) + O(\max_\pi \text{vol}(\pi(\Omega))),
\]
where the maximum runs over the projections \( \pi \) of \( \mathbb{R}^n \) onto its various coordinate hyperplanes (i.e., the regions in \( \mathbb{R}^d \) for \( d < n \) obtained by “forgetting” \( n-d \) of the coordinates). The implicit constants depend only on the dimension \( n \) and the degrees of the equations defining \( \Omega \).

**Proof of Lemma 3.2.** Define \( \Omega_{H,Y} \subseteq \mathbb{R}^n \) to be
\[
\Omega_{H,Y} := \{(c_1, \ldots, c_n) \in \mathbb{R}^n : |c_i| \leq H^2, \text{Disc}(x^n + c_1 x^{n-1} + \cdots + c_n) \leq H^{n^2-n}/Y \}.
\]
The maximum volume of the coordinate projections of \( \Omega_{H,Y} \) is trivially \( O_n(H^{\frac{n^2}{2}-n-1}) \), coming from forgetting the discriminant condition and using the coordinate projection \( (c_1, \ldots, c_n) \mapsto (c_2, \ldots, c_n) \). By Lemma 3.3, the statement thus reduces to showing that \( \text{vol}(\Omega_{H,Y}) \ll_n H^{\frac{n^2}{2}-n}/Y^{\frac{1}{2} + \frac{1}{n}} \). Since the region \( \Omega_{H,Y} \) is obtained by an anisotropic dilation we find \( \text{vol}(\Omega_{H,Y}) = H^{\frac{n^2}{2}-n}\text{vol}(\Omega_{1,Y}) \). Thus it suffices to bound \( \text{vol}(\Omega_{1,Y}) \). Taking \( \delta = Y^{-1} \) and \( Q_v = \mathbb{R} \) in Proposition 3.1, we immediately deduce that
\[
\text{vol}(\Omega_{1,Y}) \ll_n Y^{-\frac{1}{2} - \frac{1}{n}}.
\]
This completes the proof. \hfill \square

This lemma implies Corollary 2.5, used in §2.1 to prove our main theorem.

**Proof of Corollary 2.5.** Take \( Y = H^2 \) in Lemma 3.2. \hfill \square
4. Nonarchimedean Fourier transforms

Recall that if \( f(x) \) is irreducible and cuts out the field \( K \), then its discriminant satisfies \( \text{disc}(f) = \text{Disc}(K)[\mathcal{O}_K : \mathbb{Z}[\alpha]]^2 \), where \( \alpha \) is a root of \( f \) over \( K \), and where \( [\mathcal{O}_K : \mathbb{Z}[\alpha]] := \text{index}(f) \). In this section, we assemble the main technical ingredients that will be used in the proof of Theorem 2.6. This theorem bounds the number of integral polynomials \( f \) whose index is large, but for which \( \text{rad}(\text{index}(f)) \) is small. This condition implies that such polynomials will have discriminants divisible by large powers of primes. We therefore begin with the following simple lemma.

**Lemma 4.1.** Let \( n \geq 2 \) and \( k \geq 1 \), and let \( p \) be prime. The set of monic polynomials \( f \in \mathbb{Z}[x] \) for which \( p^{2k} \) divides the discriminant of \( f \) is determined by congruence conditions \( (\mod p^{2k}) \) with relative density \( O_n(p^{-k-\frac{2k}{n}}) \).

**Proof.** The fact that this condition is determined from congruence conditions follows from the fact that the discriminant of a polynomial is a polynomial in its coefficients. The density of these congruence conditions may be determined by computing the Haar measure of the set of monic polynomials in \( \mathbb{Z}_p[x] \) satisfying this condition. Therefore, the claim about the density follows from Proposition 3.1 by taking \( \mathbb{Q}_p = \mathbb{Q}_p \) and \( \delta = p^{-2k} \).

We now introduce the main object of study in this section. Let \( V(\mathbb{Z}/p^{2k}\mathbb{Z}) \) be the set of monic degree \( n \) polynomials over \( \mathbb{Z}/p^{2k}\mathbb{Z} \), and let \( \psi_{p^{2k}} \) be the characteristic function of the subset of polynomials whose discriminant is congruent to 0 (mod \( p^{2k} \)). For any \( u \in \mathbb{Z}^n \), we define the Fourier transform \( \hat{\psi}_{p^{2k}}(u) \) of \( \psi_{p^{2k}} \) by

\[
\hat{\psi}_{p^{2k}}(u) := \frac{1}{p^{2kn}} \sum_{c \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n} \psi_{p^{2k}}(f_c) \exp\left(\frac{2\pi i \langle c, u \rangle}{p^{2k}}\right),
\]

where \( f_c(x) = x^n + c_1 x^{n-1} + \cdots + c_n \) and \( \langle \cdot, \cdot \rangle \) denotes the standard inner product.

We begin with a series of lemmas that will be used to determine the support of \( \hat{\psi}_{p^{2k}} \).

**Lemma 4.2.** Write the monic polynomial \( f \) as \( f(x) = x^n - \sigma_1 x^{n-1} + \cdots + (-1)^k \sigma_k x^{n-k} + \cdots + \sigma_n (-1)^n \). For each \( 1 \leq i \leq n \), define \( D_i := \frac{\partial \text{disc}(f)}{\partial \sigma_i} \in \mathbb{Z}[\sigma_1, \ldots, \sigma_n] \). Then the discriminant \( \text{disc}(f) \) and partial derivatives \( D_i \) satisfy

1. For any \( 1 \leq r \leq r + k \leq n \) and \( 1 \leq s - k \leq s \leq n \), we have \( \text{disc}(f)|(D_rD_s - D_{r+k}D_{s-k}) \).
2. \( \sum_{1 \leq i \leq n} D_i \cdot (n + 1 - i) \cdot \sigma_{i-1} = 0 \) where we define \( \sigma_0 = 1 \).

**Proof.** For each \( n \), we define the change of variable \( \lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n \to \sigma = (\sigma_1, \cdots, \sigma_n) \in \mathbb{C}^n \) via

\[
\sigma_i(\lambda) = \sum_{S \subseteq \{1, \ldots, n\} \atop |S| = i} \prod_{j \in S} \lambda_j
\]

for \( i = 1, \ldots, n \). These are the elementary symmetric polynomials in \( \lambda_i \).

Our first goal is to give an expression for \( D_i(\sigma(\lambda)) \in \mathbb{C}[\lambda] \). A quick computation verifies that

\[
\frac{\partial \sigma_i}{\partial \lambda_j} = \sigma_{i-1}(\lambda_1, \ldots, \hat{\lambda}_j, \ldots, \lambda_n),
\]

where we write \( \hat{\lambda}_j \) to indicate that the \( j \)th coordinate should be omitted. Below, we use the shorthand \( \hat{\lambda}_j = (\lambda_1, \ldots, \hat{\lambda}_j, \ldots, \lambda_n) \). Indeed, let \( B(\lambda) \) denote the Jacobian matrix \((B_{ij})\) with \( B_{ij} = \frac{\partial \sigma_i}{\partial \lambda_j} \). When \( \lambda_i \neq \lambda_j \) for all \( i \neq j \), we define the matrix \( A(\lambda) = (A_{ij}) \) by

\[
A_{ij} = \lambda_i^{n-j}(-1)^{j+1} \prod_{k \neq i} (\lambda_i - \lambda_k).
\]
Then one can verify that 
\[(AB)_{ij} \prod_{k \neq i} (\lambda_i - \lambda_k) = (\lambda_i^{n-1}\sigma_0(\lambda_j) - \lambda_i^{n-2}\sigma_1(\lambda_j) + \cdots + (-1)^{n-1}\sigma_{n-1}(\lambda_j)) = \prod_{k \neq j} (\lambda_i - \lambda_k).\]
To see the last equality, we used the identity 
\[\prod_{i=1}^{n-1} (x - a_i) = \sum_{k=0}^{n-1} (-1)^{k+1} \sigma_k(a)x^{n-1-k}\]
for expressing a polynomial with roots \(a = (a_1, \ldots, a_{n-1})\) in terms of the elementary symmetric polynomials in these roots. This shows that \((AB)_{ij}\) is 0 if \(i \neq j\) and is equal to 1 if \(i = j\), hence \(AB = I\).

By the inverse function theorem and chain rule, we obtain the inverse function \(\lambda_i = \lambda_i(\sigma)\) with 
\[\frac{\partial \lambda_i}{\partial \sigma_i} = A_{ij}, \quad \text{and} \quad \frac{\partial D}{\partial \sigma_i} = \sum_j \frac{\partial D}{\partial \sigma_j} \frac{\partial \lambda_j}{\partial \sigma_i} = \sum_j \frac{\partial D}{\partial \lambda_j} A_{ij}.
\]
By an abuse of notation, we write \(\text{disc}(c) := D(c) := \text{disc}(f_c)\), and with \(f = x^n - \sigma_1 x^{n-1} + \cdots + (-1)^n \sigma_n\) as in the lemma statement, we write \(D = \text{disc}(f)\). For \(\sigma = (\sigma_1, \ldots, \sigma_n) = \sigma(\lambda)\), we note that (4.2) also shows that the roots of \(f\) are precisely the \(\lambda_i\). Thus \(D(\sigma(\lambda)) = \prod_{i<k}(\lambda_i - \lambda_j)^2\), and we have 
\[\frac{\partial D}{\partial \lambda_j} = 2D \sum_{k \neq j}(\lambda_j - \lambda_k)^{-1}.\]
This implies that 
\[D_i := \frac{\partial D}{\partial \sigma_i} = 2D \sum_j \lambda_j^{n-i}(-1)^{i+1} \prod_{k \neq j}(\lambda_j - \lambda_k)^{-1} \cdot (\sum_{k \neq j}(\lambda_j - \lambda_k)^{-1}) = 2D \sum_j \lambda_j^{n-i}(-1)^{i+1} \cdot W_j,
\]
where we denote 
\[W_j = \prod_{k \neq j}(\lambda_j - \lambda_k)^{-1} \cdot (\sum_{k \neq j}(\lambda_j - \lambda_k)^{-1}.
\]
Observe that 
\[DW_j = \prod_{i<k,i\neq j,k\neq j} (\lambda_i - \lambda_k)^2 \cdot \prod_{k \neq j}(\lambda_j - \lambda_k) \cdot (\sum_{k \neq j}(\lambda_j - \lambda_k)^{-1}^{-1} \cdot 4DW_j.
\]
is a polynomial in \(\mathbb{C}[\lambda]\). We thus obtain \(D_i(\lambda)\) as a polynomial in the Zariski open set \(D(\lambda) \neq 0\) in the affine space of \(\lambda\). As \(D_i(\sigma(\lambda))\) agrees with \(D_i(\lambda)\) in this open set, they agree everywhere in \(\lambda\) affine space (and not merely when \(\lambda_i \neq \lambda_j\) for all \(i \neq j\)).

We now evaluate \(D_i\). Notice that \(DW_j\) is zero if \(\lambda_j\) is a triple root of \(f\), or if there exists a double root \(\lambda_i = \lambda_k\) with \(i,k \neq j\). If there is a unique double root \(\lambda_j = \lambda_{k_0}\), then \(DW_j = \prod_{i<k,i\neq j,k\neq j}(\lambda_i - \lambda_k)^2 \prod_{k \neq j,k_0}(\lambda_j - \lambda_k) = DW_{k_0}\). Stated differently — if \(f\) has two distinct pairs of double roots or a triple root, then \(D_i = 0\) for all \(i\). If there is a unique double root \(\lambda_j\), then for any \(i\) we compute 
\[D_i = (-1)^{i+1}\lambda_j^{n-i} \cdot 4DW_j.
\]
Therefore as a polynomial in \(\mathbb{C}[\sigma]\), it follows that 
\[D_rD_s - D_{r+k}D_{s-k} = 4DW_j(-1)^{r+s} \cdot (\lambda_j^{2n-r-s} - \lambda_j^{2n-r-s}) = 0\]
on the variety cut out by \(D(\sigma) = 0\). Since \(D(\sigma)\) is irreducible, it follows from Hilbert’s Nullstellensatz that \(D \mid D_rD_s - D_{r+k}D_{s-k}\).

In order to prove the second statement, notice that discriminant is translation invariant. That is, \(\text{disc}(\lambda_1 + t, \lambda_2 + t, \ldots, \lambda_n + t) = \text{disc}(\lambda_1, \lambda_2, \ldots, \lambda_n)\). Now we can consider the function \(\sigma_i(t) := \sigma_i(\lambda_1 + t, \lambda_2 + t, \ldots, \lambda_n + t)\). It is clear that 
\[\frac{dD(\sigma(t))}{dt} \bigg|_{t=0} = \sum_i \frac{\partial D}{\partial \sigma_i} \frac{d\sigma_i}{dt} \bigg|_{t=0} = \sum_i D_i \cdot \sigma_{i-1} \cdot (n - i + 1) = 0,
\]
completing the proof. \(\square\)
This lemma is general. We exploit the relationship $D \mid D_r D_s - D_{r+k} D_{s-k}$ below, but we note that there are many other algebraic relationships on the discriminant and its derivatives that might yield further refinements on the structure of the support of $\psi P_{2k}$. In practice, we use the following more specific lemma.

**Lemma 4.3.** Given $c \in \mathbb{Z}^n$ corresponding to a polynomial $f_c(x)$ with $\text{disc}(f_c) \equiv 0 \mod p^{2k}$, let $D_c := (\frac{\partial \text{disc}(f)}{\partial c_1}, \ldots, \frac{\partial \text{disc}(f)}{\partial c_n})$ denote the gradient vector of the discriminant function, and let $v_i(c)$ denote the valuation at $p$ of $\frac{\partial \text{disc}(f)}{\partial c_i}(c) = D_i(c)$.

Then there either exists $a \in \mathbb{Z}_{\geq 0}$ such that

$$\min\{v_i(c), k\} = \min\{v_n(c) + (n - i)a, k\} \quad (4.3)$$

or $b \in \mathbb{Z}$ with $0 \leq b \leq \min(\text{val}_p(n), k)$ such that

$$\min\{v_i(c), k\} = \min\{v_1(c) + (i - 1)b, k\}. \quad (4.4)$$

Intuitively, $\min\{v_i(c), k\}$ almost forms an arithmetic progression, except that when a term is greater than $k$ we change it to $k$. Thus this lemma shows that the support of $\psi P_{2k}$ is constrained to these “near arithmetic progressions”.

**Proof.** By Lemma 4.2 (1), we see that when $p^{2k} \mid \text{disc}(f_c)$, $p^{2k} \mid D_r(c)D_s(c) - D_{r+\ell}(c)D_{s-\ell}(c)$ for all relevant $r, s, \ell$. This implies the valuation relations $\min\{v_r(c) + v_s(c), 2k\} = \min\{v_{r+\ell}(c) - v_{s-\ell}(c), 2k\}$. Specializing to $r = s = i$ and $\ell = 1$ gives that $\min\{2v_i(c), 2k\} = \min\{v_{i-1}(c) + v_{i+1}(c), 2k\}$. Thus $(v_{i-1}(c), v_1(c), v_{i+1}(c))$ is an arithmetic progression when $v_i(c) < k$ and “nearly” an arithmetic progression otherwise.

It is not possible for the sequence $\min\{v_i(c), k\}$ to initially increase and later decrease. To see this, suppose $v_i(c)$ is one such sequence for the sake of contradiction. Let $m$ denote the smallest index such that $v_m(c) \geq k$ and $M$ denote the largest index such that $v_M(c) \geq k$. Note that necessarily $1 < m \leq M < n$, as otherwise the sequence cannot increase and later decrease. Taking $r = m$, $s = M$, and $\ell = 1$ shows that $p^{2k} \mid D_m(c)D_M(c) - D_{m-1}(c)D_{M+1}(c)$, and thus that $p^{2k} \mid D_{m-1}(c)D_{M+1}(c)$. It follows that at least one of $v_{m-1}(c)$ or $v_{M+1}(c)$ is at least $k$, contradicting either the minimality of $m$ or the maximality of $M$.

Hence the sequence $\min\{v_i(c)\}$ is either non-increasing (giving (4.3)) or non-decreasing (giving (4.4)). Note that Lemma 4.2(2) implies that $n D_1(c)$ is in the ideal generated by $(D_2(c), \ldots, D_n(c))$, which restricts $b \leq \min\{\text{val}_p(n), k\} \leq n$ in (4.4).

Lemma 4.3 implies that the support of $\widetilde{\psi P_{2k}}$ is also on “near arithmetic progressions.”

**Lemma 4.4** (Support on near arithmetic progressions). For $u = (u_1, \ldots, u_n) \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n$, we have that

$$\widetilde{\psi P_{2k}}(u) = 0$$

unless $u$ satisfies one of the two “near arithmetic progression” properties that

$$\min\{v_p(u_i), k\} = \min\{v_p(u_n) + (n - i)a, k\} \quad (4.5)$$

for some $a \in \mathbb{Z}_{\geq 0}$, or

$$\min\{v_p(u_i), k\} = \min\{v_p(u_1) + (i - 1)b, k\} \quad (4.6)$$

for some $b \in \mathbb{Z}$ with $0 \leq b \leq \min\{v_p(n), k\}$.

**Proof.** For each $c \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n$ such that $p^{2k} \mid \text{disc}(f_c)$, we associate the hyperplane

$$P_c := \{v \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n : p^{2k} \mid \text{disc}(f_v), v - c \in p^k \cdot (\mathbb{Z}/p^{2k}\mathbb{Z})^n\}.$$
Two such hyperplanes $P_c$ and $P_v$ are equal if and only if $v - c \equiv 0 \mod p^k$. Thus we can decompose the set of congruence classes of polynomials whose discriminant is divisible by $p^{2k}$ into a disjoint union of $P_c$ over a set $C$ of representatives $c$ from $p^k(\mathbb{Z}/p^{2k}\mathbb{Z})^n$ satisfying $p^{2k} \mid \text{disc}(f_c)$, giving

$$\psi_{p^{2k}} = \sum_{c \in C} \widehat{1}_{P_c}.$$ 

This leads us to study $\widehat{1}_{P_c}$. Below, we use the notation $D_c$ for the gradient vector of the discriminant function and the notation $v_i$ for the $p$-valuation for the $i$th coordinate of $D_c$ as in Lemma 4.3. From the Taylor expansion

$$\text{disc}(f_v) \equiv \text{disc}(f_c) + D_c \cdot (v - c) \mod p^{2k}$$

and the fact that $p^{2k} \mid \text{disc}(f_c)$, $P_c$ for each $c \in C$, we see that $P_c$ can be written as

$$P_c = \left\{ v \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n : D_c \cdot \frac{v - c}{p^{k}} \equiv 0 \mod p^{k} \right\}. \quad (4.7)$$

Direct computation on the definition shows

$$\widehat{1}_{P_c}(\xi) = \frac{\exp\left(2\pi i (\xi, c)\right)}{p^{2kn}} \sum_{v \in P_c} \exp\left(2\pi i \frac{\langle \xi, v - c \rangle}{p^{2k}}\right). \quad (4.8)$$

Let $w := \min(v_i(c))$ denote the minimum valuation among the coordinates of $D_c$. We will now show that

$$\widehat{1}_{P_c}(\xi) = \begin{cases} 
\exp(2\pi i (\xi, c)) \cdot \frac{p^{w-k}}{p^{kn}}, & \xi \equiv \alpha D_c \pmod{p^{k}} \text{ for some } \alpha \in \mathbb{Z}/p^{k}\mathbb{Z} \\
0, & \text{otherwise.}
\end{cases} \quad (4.9)$$

To see this, first note that by (4.7), the set $P_c - c$ forms an additive group. This implies that

$$\sum_{v \in P_c} \exp\left(2\pi i \frac{\langle \xi, v - c \rangle}{p^{2k}}\right) = \exp\left(2\pi i \frac{\langle \xi, u - c \rangle}{p^{2k}}\right) \sum_{v \in P_c} \exp\left(2\pi i \frac{\langle \xi, v - c \rangle}{p^{2k}}\right) \quad (4.10)$$

for any $u \in P_c$.

When $\xi \equiv \alpha D_c \pmod{p^{k}}$ for some $\alpha \in \mathbb{Z}/p^{k}\mathbb{Z}$, all summands in (4.8) are equal to 1 by the definition of $P_c$ in (4.7). The first case of (4.9) follows from the fact that $|P_c| = p^{k(n-1)+w}$. If $\xi$ cannot be written as $\alpha D_c$, then there must be some $u \in P_c$ such that $\langle \xi, u - c \rangle \neq 0 \pmod{p^{2k}}$. Inserting this choice of $u$ into (4.10) shows that $\widehat{1}_{P_c}(\xi) = 0$. Thus (4.9) is shown.

It follows that for all $u$ in the support of $\psi_{p^{2k}}$, $u \equiv \alpha D_c$ for some $c$. The near arithmetic progression conditions (4.5) and (4.6) are then implied by Lemma 4.3. □

For the phases $u = (u_1, \ldots, u_n)$ for which the Fourier transform $\psi_{p^{2k}}(u)$ does not vanish, we will need an improvement over the trivial bound $|\psi_{p^{2k}}(u)| \leq |\psi_{p^{2k}}(0)| \ll_n p^{-k-\frac{2k}{n}}$ given by Lemma 4.1. In fact, for our purposes, it will suffice to restrict our attention to those phases for which only $u_1$ and $u_2$ are possibly non-zero. For the phases $u = (u_1, \ldots, u_n)$ in which only $u_1$ is non-zero, we observe that the Fourier transform is typically 0.

**Lemma 4.5.** Let $p$ be prime, $n \geq 6$, and $k \geq 3$. Suppose that $u_1 \in \mathbb{Z}$, and define $u \in \mathbb{Z}^n$ by $u = (u_1, 0, 0, \ldots, 0)$. Then $\psi_{p^{2k}}(u) = 0$ if $p^{2k} / \gcd(p^{2k}, n)$ does not divide $u_1$.

**Proof.** Since only $u_1 \neq 0$, by definition, we have

$$\psi_{p^{2k}}(u) = \frac{1}{p^{2kn}} \sum_{c \in (\mathbb{Z}/p^{2k}\mathbb{Z})^n} \psi_{p^{2k}}(f_c) \exp\left(\frac{2\pi ic_1 u_1}{p^{2k}}\right).$$
As the map \( x \mapsto x + 1 \) induces a bijection from the support of \( \psi_{p^{2k}} \) to itself (that is, on the set of polynomials whose discriminant is divisible by \( p^{2k} \)), sending \( c_1 = c_1(f) \) to \( c_1 + n \) for each \( f \), we also have
\[
\widehat{\psi}_{p^{2k}}(u) = \frac{1}{p^{2nk}} \sum_{c \in \mathbb{Z}/p^{2k}\mathbb{Z}} \psi_{p^{2k}}(f_c) \exp\left( \frac{2\pi i (c_1 + n) u_1}{p^{2k}} \right).
\]
This implies that either \( \widehat{\psi}_{p^{2k}}(u) = 0 \) or \( p^{2k} \mid n u_1 \). \(\square\)

To study phases \( u = (u_1, \ldots, u_n) \) with both \( u_1 \) and \( u_2 \) non-zero, we’ll use the following additional result.

**Lemma 4.6.** Let \( p \) be prime, \( n \geq 6 \), and \( k \geq 3 \). Suppose that \( u_1, u_2 \in \mathbb{Z} \), and define \( u \in \mathbb{Z}^n \) by \( u = (u_1, u_2, 0, \ldots, 0) \). Then
\[
\widehat{\psi}_{p^{2k}}(u) \ll_n p^{-\frac{2nk}{3}} \gcd(u_2, p^{2k})^{\frac{n}{3}}.
\]

**Proof.** Let \( e_{p^{2k}} : \mathbb{Z}_p \to \mathbb{C} \) be the continuous extension of the map defined on integers \( x \) by \( e_{p^{2k}}(x) := \exp\left( \frac{2\pi i x}{p^{2k}} \right) \). From Lemma 4.1, it follows that we may rewrite the Fourier transform as
\[
\widehat{\psi}_{p^{2k}}(u) = \int_{V(\mathbb{Z}_p)} \psi_{p^{2k}}(f)e_{p^{2k}}(u_1 c_1(f) + u_2 c_2(f)) d\nu(f),
\]
where \( c_1(f) \) and \( c_2(f) \) respectively denote the coefficients of \( x^{n-1} \) and \( x^{n-2} \) in \( f \). Applying the change of variables from the proof of Proposition 3.1, and with the notation from that proof, we find this integral is equal to
\[
\sum_{[K_p : \mathbb{Q}_p] = n} \frac{|\text{Disc}(K_p)|^{1/2}}{|\text{Aut}(K_p)|} \int_{\mathcal{O}_{K_p}} |\text{Disc}(f_\alpha)|^{1/2} \psi_{p^{2k}}(f_\alpha)e_{p^{2k}}(-u_1 \sigma_1(\lambda) + u_2 \sigma_2(\lambda)) d\mu(\alpha),
\]
where \( f_\alpha \) is the characteristic polynomial of \( \alpha \) and \( \sigma_i(\lambda) \) denotes the \( i \)th elementary symmetric function in the roots \( \lambda \). Fixing the étale algebra \( K_p \), we note that \( \sigma_1 \) is linear as a polynomial in \( \lambda \), and is therefore also linear in the choice of coordinates \( \alpha \in \mathbb{Z}_p^n \) from the proof of Proposition 3.1 (which we use in this proof as well). Additionally, \( \sigma_2 \) is a quadratic form in \( \lambda \) with Gram matrix
\[
Q = \begin{pmatrix}
0 & 1 & 1 & \ldots & 1 \\
1 & 0 & 1 & \ldots & 1 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
1 & 1 & 1 & \ldots & 0
\end{pmatrix},
\]
that is, \( \sigma_2(\lambda) = \frac{1}{2} \lambda^T Q \lambda \), where we regard \( \lambda \) as a column vector. As \( \lambda = M_{K_p} \alpha \), we therefore find that \( \sigma_2 \), as a polynomial in \( \alpha \), has Gram matrix \( M_{K_p}^T Q M_{K_p} \). For convenience in what is to come, we note now that \( \det Q = (-1)^{n-1}(n-1) \). Thus \( |\det M_{K_p}^T Q M_{K_p}| = \ll_n |\text{Disc}(K_p)|^{-1} \), where \( M_{K_p} \) is as in Proposition 3.1.

Let \( \alpha = (a_1, \ldots, a_n) \in \mathbb{Z}_p^n \) denote a point associated to the point \( \alpha \in \mathcal{O}_{K_p} \) in the support of \( 1_{p^{2k}} \). By continuity in each coordinate, for each \( i \leq n \) there is a minimal integer \( r_i \geq 0 \) such that whenever \( \alpha' \in \mathbb{Z}_p^n \) satisfies \( a'_i \equiv a_i \mod p^{r_i} \) and \( a'_j = a_j \) for \( j \neq i \), then \( |\text{Disc}(\alpha')|_p = |\text{Disc}(\alpha)|_p \). These integers \( r_i \) are precisely dictated by congruences between the roots \( \lambda \). We now leverage this perspective in two separate but related considerations: bounding the density of points \( \alpha \) for which there are “many” large \( r_i \), and estimating the valuation of the discriminant at such a point.

To this end, we let \( \ell = k - \frac{\nu_p(u_2)}{2} \) and set \( m \) to be equal to the number of \( i \) for which \( r_i > \ell \). In the following, we write \( a \equiv b \mod p^\ell \) to mean that \( \nu_p(a-b) \geq \ell \) to also handle the case when \( \ell \) is a half integer.

If \( a_i \mid u \) is associated to an \( r_i \) greater than \( \ell \), then at least one pair of roots must act as an obstruction; namely one of the roots \( \lambda \) for which \( a_i \) is a coefficient is subject to a congruence \( \lambda \equiv \lambda' \mod p^\ell \).
where $\lambda'$ is some other root (and where the congruence is as polynomials in the appropriate integral bases). Using the Galois action, we see that every root for which $a_i$ is a coefficient will be subject to such a congruence, and thus we may regard this congruence as being of the form $\alpha_i \equiv \gamma(\alpha_j) \pmod{p^f}$ for some nontrivial $\gamma \in \text{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)$.

Fixing an ordering $K_p = F_1 \times \cdots \times F_r$ and letting $n_i$ denote the degree of $F_i$, we seek to bound the density of the points $a \in \mathbb{Z}_p^n$ with $m$ values of $r_i > \ell$. To do this, we iterate through the $F_i$ and thus also the associated $\alpha_i$, beginning with $i = 1$. For each $i$, let $j$ denote the least index such that $\alpha_i \equiv \gamma(\alpha_j) \pmod{p^f}$.

1. If $\alpha_i$ is not subject to such a congruence, we bound its contribution to the density trivially.
2. We now study when there is a congruence of the form $\alpha_i \equiv \gamma(\alpha_j) \pmod{p^f}$ for some $j < i$.
   
   In this case, $\alpha_i$ is completely determined mod $p^f$ (as $j < i$, and thus this iterative procedure has already accounted for those $\alpha_j$), each of the $n_i$ associated values $r_i$ are greater than $\ell$, and the density of points $a$ satisfying the correct congruence is at most $p^{-\ell n_i}$.
3. Suppose instead that there is a congruence of the form $\alpha_i \equiv \gamma(\alpha_j) \pmod{p^f}$ with $j > i$. It remains true that all of the $n_i$ associated values $r_i$ are greater than $\ell$, but this iterative procedure has not yet studied $\alpha_i$. We note, however, that $\alpha_i$ must be congruent (mod $p^f$) to an element of the intersection $F_i \cap \gamma(F_i)$, which will be satisfied for at most $p^{-\ell n_i/2}$ of the points if it is a proper subextension of $F_i$.
4. Finally, we consider the possibility that $\alpha_i \equiv \gamma(\alpha_i) \pmod{p^f}$ for some nontrivial $\gamma \in \text{Gal}(\overline{F}_i/\mathbb{Q}_p)$. Let $|\gamma|$ denote the order of $\gamma$. Taking traces shows that $|\gamma|\alpha_i$ must be congruent (mod $p^f$) to an element of the subfield $F_i^{\gamma}$ of $F_i$ fixed by $\gamma$. Since $\gamma$ acts nontrivially on the conjugates of $F_i$, this subfield has degree at most $n_i/2$, from which it follows that at least $n_i/2$ values $r_i$ are greater than $\ell$, and further that the density of points satisfying this condition is at most $O\left(p^{-\ell n_i/2}\right)$.

Pulling together these considerations, we conclude that the density of points $a$ for which there are $m$ values $r_i > \ell$ is at most $p^{-m/2}$, corresponding to the situation where there are $m/2$ pairs of roots that are congruent (mod $p^f$). For the same reason, we observe that $|\text{Disc}(f_a)|_{p^{1/2}} \leq p^{-m/2} |\text{Disc}(K_p)|_{p^{1/2}}$ for any such point.

Now, for the $n - m$ remaining coordinates $a_i$ with $r_i \leq \ell$, we may change $a_i$ by an arbitrary multiple of $p^{\ell i}$ while preserving the discriminant. Motivated by the method of (non)stationary phase, by Taylor expanding, we then observe that

$$u_2\sigma_2(a + b_i p^{\ell i}) - u_1\sigma_1(a + b_i p^{\ell i}) \equiv u_2\sigma_2(a) - u_1\sigma_1(a) + b_i p^{\ell i} \cdot \left(u_2 \frac{\partial \sigma_2}{\partial a_i}(a) - u_1 \frac{\partial \sigma_1}{\partial a_i}(a)\right) \pmod{p^{2k}},$$

where we use $b_i$ to indicate a vector whose only nonzero component is $b_i$ in the $i$th coordinate. We note that we’ve used that $\sigma_1(a)$ is linear in $a_i$ and the relationship between $\ell$ and $u_2$ in omitting higher derivatives. This implies that the integral

$$\int_{b_i \in \mathbb{Z}_p} |\text{Disc}(f_a)|_{p^{1/2}} \psi_p^{2k}(f_{\alpha}) c_{p^{2k}}(-u_1\sigma_1(a + b_i p^{\ell i}) + u_2\sigma_2(a + b_i p^{\ell i})) \, db_i$$

will vanish unless the congruence $u_2 \frac{\partial \sigma_2}{\partial a_i}(a) - u_1 \frac{\partial \sigma_1}{\partial a_i}(a) \equiv 0 \pmod{p^{2k-\ell}}$ is satisfied. Consequently, we may restrict the integral

$$\int_{O_{K_p}} |\text{Disc}(f_a)|_{p^{1/2}} \psi_p^{2k}(f_{\alpha}) c_{p^{2k}}(-u_1\sigma_1(\lambda) + u_2\sigma_2(\lambda)) \, d\mu(\alpha)$$

to those points satisfying the congruence $u_2 \frac{\partial \sigma_2}{\partial a_i}(a) - u_1 \frac{\partial \sigma_1}{\partial a_i}(a) \equiv 0 \pmod{p^{2k-\ell}}$ for each $a_i$ with $r_i \leq \ell$. Since $\sigma_2$ is quadratic, these are linear constraints, and they will be independent over $\mathbb{Z}_p$ since the coefficients of $\frac{\partial \sigma_2}{\partial a_i}$ are precisely the entries of the $i$th column of the Gram matrix $M^T_{K_p} Q M_{K_p}$, which is nonsingular by our earlier computation. In fact, the same computation reveals that the
density of points \( a \in \mathbb{Z}_p^n \) satisfying these conditions will be at most \( p^{-(n-m)[\ell]} |\text{Disc}(K_p)|^{-1} \). This bound is of the shape \( p^{-(n-m)[\ell]} |\text{Disc}(K_p)|^{-1} \) if \( \ell \) is an integer, which will be sufficient for our purposes.

We now argue that if \( \ell \) is a half-integer (so that \( [\ell] = \ell - \frac{1}{2} \)), then it is possible to extract a further saving of \( p^{-1/2} \) in each of these \( n-m \) coordinates; in total this will yield a bound of the same form \( p^{-(n-m)[\ell]} |\text{Disc}(K_p)|^{-1} \) regardless of whether \( \ell \) is an integer. In particular, for each \( a_i \) for which the coefficient of \( a_i^2 \) in \( \sigma_2(a) \) is 0 or has positive valuation, we may repeat the argument above but changing \( a_i \) by an arbitrary multiple of \( p^{[\ell]} \); for such coordinates, we in fact extract a saving of \( p^{-1} \).

For the coordinates for which the coefficient of \( a_i^2 \) in \( \sigma_2(a) \) is a unit, the nonstationary phase constraint implies that the integral

\[
\int_{b_i \in \mathbb{Z}_p} |\text{Disc}(f_\alpha)|^{1/2} e_{p^{ivk}}(f_\alpha)e_{p^{2v}}(-u_1\sigma_1(a + b_ip^{[\ell]}) + u_2\sigma_2(a + b_ip^{[\ell]})) \, db_i
\]

reduces to a nontrivial quadratic Gauss sum modulo \( p \). This may be bounded by \( O(p^{1/2}) \), which realizes the claimed saving of \( p^{-1/2} \) over the trivial bound for these coordinates.

We now recall that the constraints on the \( m \) variables \( a_i \) with \( r_i > \ell \) have density at most \( p^{-mt/2} \). We expect that these constraints are independent from those on the \( n-m \) variables coming from the nonstationary phase, but we do not exploit. Instead, we simply take the smaller of the two bounds. Accounting for the valuation of the discriminant at such points as described above, and accounting for the factor of \( |\text{Disc}(K_p)|^{1/2} \) appearing in (4.11), we find that such points contribute at most \( O_n(\min\{p^{-mt}, p^{-(n-m)[\ell]}\}) \) to (4.11). Accounting for the at most \( 2^n \) possibilities for \( m \) and the choices of \( r_i > \ell \), we find altogether that

\[
\frac{|\text{Disc}(K_p)|^{1/2}}{|\text{Aut}(K_p)|} \int_{\text{cusp}} |\text{Disc}(f_\alpha)|^{1/2} e_{p^{ivk}}(f_\alpha)e_{p^{2v}}(-u_1\sigma_1(\lambda) + u_2\sigma_2(\lambda)) d\mu(\alpha) \ll_n p^{-2\ell}. 
\]

Adding this across the \( O_n(1) \) étale algebras, and recalling that \( \ell = k - \frac{v_p(u_2)}{2} \), we deduce the result. \( \square \)

5. POLYNOMIALS WITH A LARGE AND POWERFUL INDEX

The main goal of this section is to prove Theorem 2.6, which states that the number of polynomials for which \( \text{index}(f) \geq H^{g(n-3)/2} \) but \( \text{rad}(\text{index}(f)) < H^{1-\epsilon} \) is \( O_n(H^{\frac{n^2}{2} - \frac{3}{4} - \frac{n-3}{2}}) \).

We begin with the following elementary lemma that, in the context of Theorem 2.6, will allow us to choose a convenient divisor of the index.

**Lemma 5.1.** Let \( m \geq 2 \) be an integer, and let \( C = \text{rad}(m) \) be the product of the primes dividing \( m \). Let \( k \geq 2 \). If \( m \geq C^{2k-2} \), then for every \( x \in \mathbb{R} \) such that \( C^{k-1} \leq x \leq m/C^{k-1} \), \( m \) has a \( k \)-powerful divisor \( d \) in the interval \([x,Cx]\).

(Recall that an integer \( d \) is \( k \)-powerful if every prime \( p \mid d \) divides \( d \) to order at least \( k \).)

**Proof.** We begin by proving a slightly stronger statement in the case that \( m \) is itself \( k \)-powerful, in particular producing a \( k \)-powerful divisor in every interval of the form \([x,Cx]\) with \( C^{k-1} \leq x \leq m/C \). If \( x \leq C^k \), then we simply take the divisor \( d \) to be \( C^k \). If \( x > C^k \), then we consider divisors of the form \( C^k a \) with \( a \) a divisor of \( m/C^k \), and we claim there must be such a divisor \( a \) in the interval \([x/C^k,x/C^{k-1}]\). If this interval includes \( m/C^k \), then we take the divisor \( a \) to be \( m/C^k \) itself. Otherwise, let \( a \) be the minimal divisor of \( m/C^k \) greater than \( x/C^{k-1} \). Then every prime divisor \( p \) of \( a \) is at most \( C \), and thus \( a/p \geq x/C^k \). On the other hand, by the minimality assumption on \( a \), \( a/p \leq x/C^{k-1} \), and thus \( a/p \) is the claimed divisor. This completes the proof in the case \( m \) is \( k \)-powerful.
If $m$ is not $k$-powerful, let $m'$ denote the maximal $k$-powerful divisor of $m$ and let $C' = \text{rad}(m')$, and notice that $C' \leq C$. Additionally, we have $m/C^{k-1} \leq m'/C^{(k-1)}$. It then follows from the previous paragraph that $m'$ has a $k$-powerful divisor in the interval $[x, C'x] \subseteq [x, Cx]$ for $x$ as in the statement of the lemma, and thus $m$ must too.

We now turn to the proof of Theorem 2.6.

**Proof of Theorem 2.6.** We wish to show that the number of monic polynomials $f(x) \in \mathbb{Z}[x]$ of degree $n$ and height $H$ for which $\text{rad}(\text{index}(f)) < H^{1-\epsilon}$ but $\text{index}(f) > H^{\frac{2n-3}{2}}$ is $O_{n,\epsilon}(H^{\frac{2n+3}{4} - \frac{3}{4} + \epsilon})$.

Suppose we are considering such a polynomial $f$. By Lemma 5.1 applied with $k = 3$, there is some cubefull divisor $d$ of the index of $f$ satisfying $H^{2-2\epsilon} < d \leq H^{3-3\epsilon}$. By the Chinese remainder theorem, given such a divisor $d$, the polynomial $f$ will lie in the support of the function $\hat{\psi}_{d^2} = \prod_{\gamma \mid d} \hat{\psi}_{p^{2\gamma}}$.

Moreover, the support of this function is determined by congruences conditions (mod $d^2$). Since $d^2 > H$, we may not simply estimate the number of such polynomials by naïvely counting the number in each residue class. Instead, we identify the space of monic, degree $n$ polynomials with $\mathbb{Z}^n$ and we let $\phi: \mathbb{R}^n \to \mathbb{R}$ be a non-negative Schwartz function, chosen so that it is greater than 1 on the unit box $[-1, 1]^n$ and so that its Fourier transform $\hat{\phi}$ has compact support contained in $[-\frac{1}{2n}, \frac{1}{2n}]^n$.

Then by Poisson summation,

$$
\sum_{c \in \mathbb{Z}^n} \phi \left( \frac{c_1}{H}, \ldots, \frac{c_n}{H^n} \right) \hat{\psi}_{d^2}(f) = H^{\frac{n^2+3n}{2}} \sum_{u \in \mathbb{Z}^n} \hat{\phi} \left( \frac{u_1H}{d^2}, \ldots, \frac{u_nH^n}{d^2} \right) \hat{\psi}_{d^2}(u)
\approx H^{\frac{n^2+3n}{2}} \hat{\psi}_{d^2}(0) \hat{\phi}(0) + H^{\frac{n^2+3n}{2}} \sum_{\theta \neq u \in \mathbb{Z}^n} \hat{\phi} \left( \frac{u_1H}{d^2}, \ldots, \frac{u_nH^n}{d^2} \right) \hat{\psi}_{d^2}(u)
$$

where $\hat{\psi}_{d^2}(u)$ is defined by

$$
\hat{\psi}_{d^2}(u) = \frac{1}{d^{2n}} \sum_{f \in (\mathbb{Z}/d^2\mathbb{Z})^n} \psi_d(f) e^{\frac{2\pi i (f, u)}{d^2}}.
$$

By the Chinese remainder theorem, $\hat{\psi}_{d^2}(u)$ may be decomposed as $\hat{\psi}_{d^2}(u) = \prod_{\gamma \mid d} \hat{\psi}_{p^{2\gamma}}(\gamma_p^i u)$ for some $\gamma_p$ coprime to $p$. Thus, $\hat{\psi}_{d^2}(u)$ may be bounded by the results of the previous section, in particular Lemma 4.1, Lemma 4.4, and Lemma 4.6. Using Lemma 4.1, the first term on the right-hand side of (5.1) is $O_{n,\phi,\epsilon}(H^{\frac{2n+3}{4} - \frac{3}{4} + \epsilon})$. Added over cubefull integers $d > H^{2-2\epsilon}$, this yields a total contribution that is $O_{n,\phi,\epsilon}(H^{\frac{2n+3}{4} - \frac{3}{4} + \epsilon})$, which matches the bound claimed in Theorem 2.6.

For the contribution from the sum of the non-trivial Fourier coefficients, we first note that by the compact support of $\hat{\phi}$, the summation is supported on those $u$ for which each $|u_i| \leq d^2/2H^i$. Since we have assumed that $d < H^{3-3\epsilon}$, this implies that $u_i = 0$ for $i \geq 6$. In particular, since $u_6 = 0$, it follows from the arithmetic progression property of the support (Lemma 4.4) of $\hat{\psi}_{d^2}$ that each $u_i$ for $i \leq 5$ must be divisible by $d/\gcd(n^{6-i}, d)$. (In the worst case, when (4.6) holds for every prime $p$ dividing $d$, we bound $b \leq v_p(n)$.) Thus, writing $u_i = (d/\gcd(n^{6-i}, d))u'_i$, we find that $u'_i$ satisfies $|u'_i| \leq d/H^i$, which in particular also implies that $u_i = 0$ for $i \geq 3$. If $u_2 = 0$, then the sum is only over integers $|u_1| \leq d^2/H$. However, by Lemma 4.5, $\hat{\psi}_{d^2}(u)$ will vanish unless $u_1$ is divisible by $d^2/\gcd(d^2, n)$, which forces $u_1 = 0$ in this range as well. As we have already considered the contribution from the trivial Fourier coefficient, we may therefore assume that $u_2 \neq 0$. 

If \( u_2 \neq 0 \), then by Lemma 4.6, 
\[
\hat{\psi}_d(u) \ll_{n, \epsilon} d^{-2n/3+\epsilon} \gcd(d^2, u_2)^{n/3} \ll_n d^{-n/3+\epsilon} \gcd(d, u_2)^{n/3}.
\]  
This case thus yields a contribution that is
\[
\ll_{n, \epsilon} \frac{H^{n^2+n+\epsilon}}{d^{n/3}} \sum_{|u'_1| \ll_n, d/H} \sum_{0 \neq u'_2 \ll_n, u'_2/H^2} \gcd(d, u'_2)^{n/3} \ll_{n, \epsilon} dH^{n^2+n-2n/3+1+\epsilon}, \tag{5.2}
\]
by noting that the summation over \( u'_2 \) is dominated by the \( O(d^\epsilon) \) values \( u'_2 \) for which \( \gcd(d, u'_2) \) is largest possible, but that this gcd is \( O_n(d/H^2) \) from the bound on \( u'_2 \). After summing over cubefull integers \( H^{2-2\epsilon} < d < H^{3-3\epsilon} \), we find a total contribution from the non-trivial Fourier coefficients that is \( O_{n, \epsilon}(H^{n^2+n-2n/3+\epsilon}) \), which completes the proof of the theorem. \( \square \)

6. Strong and weak multiples

In this section, we prove Theorem 2.7, which bounds the number of polynomials of height \( H \) whose discriminants have large squarefree divisors. To do this, we build on the work of Bhargava, Shankar, and Wang [BSW22]. As before, to any \( c = (c_1, \ldots, c_n) \in \mathbb{Z}^n \) we associate the monic degree \( n \) polynomial \( f_c(x) = x^n + c_1 x^{n-1} + \cdots + c_n \).

Theorem 2.7 should be compared with [BSW22, Theorem 4.4], where a similar statement is proven but where the second term is \( H^{n^2+n-2n/3+\epsilon} \) instead of \( H^{n^2+n-2n/3+1+\epsilon} \). It should also be compared with [BSW, Theorem 4], where a strictly stronger statement is proven. Additionally, as sketched in [BSW22], it is possible to prove that the first term on the right-hand side is \( H^{n^2+n}/M \), but we do not pursue this as it is not necessary in the proof of our main theorem.

To prove Theorem 2.7, we follow the same strategy as [BSW22], offering improvements to each of the two key steps. For a squarefree integer \( m \), let \( \mathcal{W}_m \) be the underlying set of polynomials whose discriminant is divisible by \( m^2 \), that is
\[
\mathcal{W}_m := \{ c \in \mathbb{Z}^n : |c_i| \leq H^i, m^2 \mid \text{disc}(f_c) \}.
\]
We decompose this set as follows. For a prime \( p \), we say that disc \((f)\) is a strong multiple of \( p^2 \) if disc \((g)\) is a multiple of \( p^2 \) for every polynomial \( g \) congruent to \( f \pmod{p} \), and we say that disc \((f)\) is a weak multiple of \( p^2 \) otherwise. Let \( \mathcal{W}_m^{(1)} \subseteq \mathcal{W}_m \) be the subset consisting of polynomials for which disc \((f)\) is a strong multiple of \( p^2 \) for every prime \( p \mid m \), and let \( \mathcal{W}_m^{(2)} \subseteq \mathcal{W}_m \) be the subset of those for which disc \((f)\) is a weak multiple of \( p^2 \) for every prime \( p \mid m \). By considering the factorization of \( m \), Bhargava, Shankar, and Wang [BSW22] make the simple observation that for any \( M > 1 \),
\[
\bigcup_{m \geq M \text{ squarefree}} \mathcal{W}_m \subseteq \bigcup_{m \geq \sqrt{M} \text{ squarefree}} \mathcal{W}_m^{(1)} \bigcup \bigcup_{m \geq \sqrt{M} \text{ squarefree}} \mathcal{W}_m^{(2)}.
\]
Thus, to prove Theorem 2.7, it is sufficient to prove the following pair of propositions that refine [BSW22, Theorem 1.5(a)] and [BSW22, Theorem 1.5(b)], respectively.

**Proposition 6.1.** For any \( Y > 1 \), \( H > 0 \), and \( \epsilon > 0 \),
\[
\bigcup_{m \geq Y \text{ squarefree}} \mathcal{W}_m^{(1)} \ll_{n, \epsilon} \frac{H^{n^2+n+\epsilon}}{Y} + H^{n^2+n-n+1+\epsilon}.
\]

**Proposition 6.2.** For any \( Y > 1 \) and any \( \epsilon > 0 \), we have
\[
\bigcup_{m \geq Y \text{ squarefree}} \mathcal{W}_m^{(2)} \ll_{n} \frac{H^{n^2+n}}{Y} + H^{n^2+n-1/2+\epsilon}.
\]

We now turn to the proofs of these propositions.
6.1. Strong multiples and Proposition 6.1. To prove Proposition 6.1, we apply a line of reasoning similar to the geometric sieve (c.f. Theorem 3.3 of [Bha14]).

Recall that each \( c \in \mathbb{Z}^n \) corresponds to a degree \( n \) polynomial \( f_c = x^n + c_1 x^{n-1} + \cdots + c_n \). The discriminant \( \text{disc}(f_c) \) is a polynomial in the coefficients \( c_i \). More generally, to any \( c \in \mathbb{R}^n \) we can associate the gradient vector \( \mathbf{D}_c := (\frac{\partial \text{disc}(f)}{\partial c_1}, \ldots, \frac{\partial \text{disc}(f)}{\partial c_n}) \). Then we see that \( \text{disc}(f_c) \) is a strong multiple of \( p^2 \) if and only if both \( \text{disc}(f_c) \equiv 0 \) mod \( p \) and \( \mathbf{D}_c \equiv 0 \) mod \( p \). Thus it suffices to bound the number of \( c \) with \( |c_i| \leq H^i \) (\( 1 \leq i \leq n \)) such that \( \text{disc}(f_c) \equiv 0 \) mod \( q \) and \( \frac{\partial \text{disc}(f)}{\partial c_n} \equiv 0 \) mod \( q \) for some squarefree integer \( q \geq Y \). To simplify, we replace \( \frac{\partial \text{disc}(f)}{\partial c_n}(c) \) by the resultant of \( \frac{\partial \text{disc}(f)}{\partial c_n}(c) \) and \( \text{disc}(f_c) \) with respect to \( c_{n-1} \). Denote the two polynomials \( \text{disc}(f_c) \) and \( \text{Res}(\text{disc}(f_c), \frac{\partial \text{disc}(f)}{\partial c_n}) \) by \( g_1(c) \) and \( g_2(c) \), respectively, where we note \( g_2(c) \) even though \( g_2 \) doesn’t depend on \( c_{n-1} \) so that it suffices to count common roots \( c \) of \( g_1 \) and \( g_2 \).

We first show that \( g_1(c) \), as a polynomial in \( \mathbb{Z}[c_1, \ldots, c_{n-2}, c_n] \), has degree \( n \) and nonzero constant leading coefficient, or equivalently that \( g_1(c) = \sum_{i<n} \alpha_i c_i c_{n-1} \) with \( \alpha_i \neq 0 \). To see this, we compute the \( g_1(c) = \text{disc}(f_c) \) via the resultant matrix \( A \) of the monic polynomial \( f_c(x) \) and its derivative \( f_c'(x) \). In this matrix, we observe that \( c_{n-1} \) occurs exactly 0 times in the first \( n-1 \) rows, twice in rows \( n \) to \((2n-2)\), and once in the \((2n-1)\)st row. Thus the degree is at most \( n \). We explicitly compute that the coefficient \( \alpha_n \) is

\[
\alpha_n = \sum_{0 \leq k \leq n-1} (-n)^k \binom{n-1}{k} = (1-n)^{n-1} \neq 0.
\]

Next, from the weighted homogeneity property of resultants, we observe that \( g_2(c) \) may be expressed as a homogeneous polynomial of degree \( n^2(n-2) \) in the roots of \( f \), and is therefore a weighted homogeneous polynomial in \( c \) of the same degree, where each \( c_i \) has weight \( i \). It therefore has degree at most \( n(n-2) \) as a polynomial in \( c_n \), and we observe that there is a unique permutation giving rise to a term of such degree in the determinant representation of the resultant, corresponding to choosing the bottom entry of the columns associated to \( \text{disc}(f_c) \) and the top entry of the columns associated to \( \frac{\partial \text{disc}(f)}{\partial c_n} \). We conclude that \( g_2(c) \), as a polynomial in \( c_n \), has degree \( n(n-2) \) and that its leading coefficient is a non-zero constant depending only on \( n \). In particular, \( g_2(c) \) will be a non-zero polynomial in \( c_n \) for any choice of the coordinates \( (c_1, \ldots, c_{n-2}) \).

The total number of tuples among the first \( n-2 \) coordinates \( (c_1, \ldots, c_{n-2}) \) satisfying \( |c_i| \leq H^i \) is of the order \( H^{n(n+1)/2-(2n-1)} \). For each such tuple, the number of \( c_n \) such that \( g_2(c_1, \ldots, c_{n-2}, c_n) = 0 \) is absolutely bounded by the degree in \( c_n \), and thus bounded by \( O_n(1) \); the number of \( c_{n-1} \) is trivially bounded by \( H^{n-1} \). These contribute at most \( O_n(H^{n(n+1)/2-n}) \) many \( c \).

If \( g_2(c_1, \ldots, c_{n-2}, c_n) \neq 0 \), then we take \( q \geq Y \) to be any squarefree number that divides \( g_2(c_1, \ldots, c_{n-2}, c_n) \); there are at most \( O_{n,a}(H^a) \) many such choices \( q \). The number of \( c_{n-1} \) with \( |c_{n-1}| \leq H^{n-1} \) such that \( g_1(c_1, \ldots, c_n) \equiv 0 \) mod \( q \) is at most \( O_n(\max\{1, H^{n-1}/Y\}) \). In total, these contribute at most \( O_n(H^{n(n+1)/2+\epsilon}/Y) + O_n(H^{n(n+1)/2+\epsilon-(n-1)}) \).

Combining these two bounds completes the proof of Proposition 6.1. \( \square \)

6.2. Weak multiples and Proposition 6.2. We now turn to Proposition 6.2, which is an improvement of the second error term in [BSW22, Theorem 1.5(b)]. Our input consists simply of the application of a sharper sieve result at the heart of their argument. In particular, the error term in question originates in Propositions 2.6 and 3.5 of [BSW22], depending on whether \( n \) is odd or even.

The proofs of both propositions rely on an application of the Selberg sieve to bound the number of “distinguished orbits” of an appropriate orthogonal group acting on the space of symmetric \( n \times n \) matrices over \( \mathbb{Q} \). For each prime \( p \), they establish that they are able to sieve out a proportion of congruence conditions which is uniformly bounded away from 0, and then an application of the Selberg sieve yields their result.
It turns out that an application of the large sieve in the form of [Ser08, Theorem 10.1.1] immediately yields the stated stronger result. We also note that further improvements might be possible, in particular by incorporating Fourier analysis when applying the Selberg sieve as a large sieve, as done in [AGLO+21].
