Abstract: In this paper, we constructed the deformed Schwarzschild black hole in the non-commutative (NC) gauge theory of gravity. Where the singularity at the origin is shifted by the non-commutativity to the finite radius $r_h = 2m$ and changed the spherical symmetry of the black hole to the ellipse symmetry (deformed the NC event horizon). The thermodynamics property of the NC black hole is analyzed. As a first step, we describe the Hawking temperature and the entropy of the NC Schwarzschild black hole, where the result shows a difference in the pole-equator temperature of the black hole, and give us a new scenario of the black hole evaporation. Our estimation for the NC parameter is close to the Planck scale $\Theta \approx 2.257 \times 10^{-35} m$. Then, the description of the ADM mass, the heat capacity, and the Gibbs free energy of the deformed black hole show the effect of the NC gauge theory on the thermodynamic stability and the phase transitions. Finally, we investigated the influence of the pressure of the black hole in the first law of thermodynamics on the stability and the phase transition of the Schwarzschild black hole in the NC spacetime, where the result shows that the NC parameter plays a similar role as the thermodynamical function and defined the critical point as the pressure in the modified first law of thermodynamics which means a second-order phase transition or a continuous one. The stability and the phase transition of the Schwarzschild black hole are affected by the non-commutativity.

Keywords: Non-commutative geometry, Gauge gravity, Schwarzschild black hole, Thermodynamics propriety.

1 Introduction

In 1915 Albert Einstein proposed one of the most successful theories of gravity. Despite the success of this theory, in predicting the experimental results with the highest precision such as the periastron advance of Mercury orbit, bending of light, gravitational red-shift, etc. Also, the prediction of the gravitational wave that was observed in 2016 by LIGO experiment [1], and the recent observation of the black hole for the first time [2] in 2019. However, this theory has some problems with the description of the gravity at the quantum scale, and this allows the emergence of many theories in this area to describe quantum gravity. The first mechanism that unifies quantum mechanics and gravity is proposed by Hawking (1975) in the context of the semi-classical approach, which happens near the event horizon, where this allows the black hole to emit the radiation and thus evaporate [3, 4]. In similarity to thermal black body radiation, also the black hole can emit a spectrum of particles, and this phenomenon is known as Hawking radiation. The thermodynamics property of the black hole is a part of the black hole phenomenology which is a part of a large research area [4–9], which is important to understand the physics of the black hole and even quantum gravity. However, Hawking demonstrated that the thermal spectrum of the Schwarzschild black hole has a temperature \( T_H = \frac{\hbar c^3}{8\pi G_k B M} \). In the final stage of the evaporation of the black hole has a divergent behavior of the temperature, for fixed this behavior we can use the NC gauge theory to remove this divergent, where this theory is motivated by the string theory [10].
The NC theory has a special commutation relation as in quantum mechanics but there is between the coordinate of the spacetime itself:

\[ [x^\mu, x^\nu] = i\Theta^{\mu\nu} \]  

(1.1)

where \( \Theta^{\mu\nu} \) is an anti-symmetric real matrix. In this way, the ordinary product between two arbitrary functions \( f(x) \) and \( g(x) \) defined over this space-time are changed to the star product (Moyal product) "\( \ast \)" which given by:

\[ (f \ast g)(x) = f(x)e^{iz^\mu\nu\frac{\partial}{\partial x^\mu}\partial g(x)} \]

(1.2)

In the last 20 years, there have been a lot of interesting studies on the modified thermodynamics property of the black hole by introducing the non-commutativity [11–19]. Here we use star products and Seiberg-Witten maps [10] to describe the gauge gravity theory in the NC space-time. In this paper, we aim to investigate the expression of the event horizon that arises from the \( g_{00} \) component, and the correction to this event horizon show a term of the first order in \( \Theta \) and depends on the observation angle \( \theta \) which gives us a similar result as the ergosphere in the commutative rotating black hole. Then we find that the singularity at the origin is removed by the non-commutativity of spacetime. In addition, we obtain a correction in terms of the NC parameter up to the second-order for each of the Hawking temperatures and entropy of the black hole. The obtained results show that the non-commutativity remove the divergent behavior of temperature and shows a difference in the pole-equator temperature of the black hole, and gives us an estimation of the \( \Theta \) in the order of Planck scale, and a new scenario of the black hole evaporation. We also checked the behavior of the heat capacity to discuss the stability of the NC black hole and we took into account the Gibbs free energy in the NC spacetime to investigate the phase transition. Then we include the pressure due to the quantum correction of the non-commutativity and that shows an intermediate region of the black hole. The swallowtail structure in the NC spacetime, and the non-commutativity show the inflection point at the critical value of \( \Theta \) which means a second-order phase transition in this geometry.

The article is organized as follows. In Sect. 2 we use the star product between tetrad fields and Seiberg-Witten maps to describe the NC corrections to the metric field. In Sect. 3 we study the thermodynamic properties of the NC black hole where the correction to the Hawking temperature and entropy of the black hole up to the second-order in \( \Theta \) are determined. Add to that, the ADM mass and the heat capacity in the NC spacetime are also obtained. The Gibbs free energy is considered in the description of the black hole thermal propriety, then we show and discussion of the phase transition for the Schwarzschild black hole in the presence of the pressure in the NC spacetime. In the last Sec, we present our remarks and conclusions.

2 Non-commutative gauge gravity for Schwarzschild black hole

The gauge theory of gravity is a theory of general relativity in the de Sitter group \( SO(4,1) \) on a commutative 4-dimensional metric with spherical symmetric in Minkowski spacetime,
which is proposed by G.Zet in the Ref. [20, 21], wherein this theory the action is invariant under the ordinary Lorentz transformation and the gauge field of the gravity in the $SO(4,1)$ group are denoted by $e^a_\mu$, $a=0,1,2,3$ for the tetrad fields and $\omega^{ab}_\mu(x) = -\omega^{ba}_\mu(x)$ for the spin connection with $[ab]=[01],[02],[03],[12],[13],[23]$. In this theory, if we preservative the NC spacetime and we based partly on implementing symmetries on flat NC spacetime, we get an NC gauge theory of gravity in curved spacetime. Since the ordinary Lorentz transformations, via the Seiberg-Witten map, induce the NC canonical transformations of deformed fields then the NC action stays invariant [9, 22, 23]. In this case the deformed gauge filed of gravity are denoted by $\hat{e}^a_\mu(x,\Theta), \hat{\omega}^{ab}_\mu(x,\Theta)$.

We interesting with the Schwarzschild black hole, let consider the following static metric and spherical symmetry:

$$ds^2 = -A(r)dt^2 + \frac{1}{A(r)}dr^2 + r^2(d\theta^2 + \sin^2\theta d\phi^2)$$

(2.1)

where the $A(r)$ are function related only to the radius $r$. In the tetrad formulation of General Relativity the tetrad components is related to the metric by this relation:

$$g_{\mu\nu} = e^a_\mu e_{a\nu}$$

(2.2)

From the general case, we take a particular form of non diagonal tetrad fields, which satisfies the relation (2.2) as follows:

$$e^a_\mu = \begin{bmatrix} A(r) & 0 & 0 & 0 \\ 0 & \frac{1}{A(r)} \sin\theta \cos\phi & \cos\theta \cos\phi - r \sin\theta \sin\phi & 0 \\ 0 & \frac{1}{A(r)} \sin\theta \sin\phi & \cos\theta \sin\phi & -r \sin\theta \\ 0 & \frac{1}{A(r)} \cos\theta & -r \sin\theta & 0 \end{bmatrix}$$

(2.3)

For the non-commutative correction to this metric, it has been obtained in Ref. [24], using the Seiberg-Witten map and the Moyal product. The deformed tetrad fields $\hat{e}^a_\mu(x,\Theta)$ can be described in the development in the power of $\Theta$ up to the second-order, which can be obtained by following the same approach in Ref. [25]:

$$\hat{e}^a_\mu(x,\Theta) = e^a_\mu(x) - i\Theta^{\nu\rho}e^a_{\mu\rho}(x) + \Theta^{\nu\rho}\Theta^{\lambda\tau}e^a_{\mu\rho\lambda\tau}(x) + \mathcal{O}(\Theta^3)$$

(2.4)

where:

$$e^a_{\mu\nu\rho} = \frac{1}{4} [\omega^{ac}_{\nu} \partial_\rho e^d_\mu + (\partial_\mu \omega^{ac}_\nu + R^{ac}_{\rho\mu})e^d_\nu] \eta_{cd}$$

(2.5)

$$e^a_{\mu\nu\rho\lambda\tau} = \frac{1}{32} \left[ 2 \{ R_{\tau\nu}, R_{\mu\rho} \}^{ab}_{\chi} e^c_{\lambda} - \omega^{ab}_\chi (D_\rho R^c_{\tau\nu} + \partial_\rho R^{cd}_{\tau\nu})e^m_{\nu} \eta_{dm} \\
- \{ \omega_{\nu}, (D_\rho R_{\tau\nu} + \partial_\rho R_{\tau\nu}) \}^{ab}_{\chi} e^c_{\lambda} - \partial_\nu \{ \omega_{\nu}, (\partial_\rho \omega_{\mu} + R_{\rho\mu}) \}^{ab}_{\chi} e^c_{\lambda} \\
- \omega^{ab}_\chi (\partial_\rho e^c_{\mu} + \partial_\mu e^c_{\rho}) e^d_{\nu} \eta_{cd} + 2 \partial_\nu \omega^{ab}_{\chi} \partial_\rho e^c_{\lambda} \\
- 2 \partial_\rho (\partial_\nu \omega^{ab}_{\chi} + R^{ab}_{\nu}) \partial_\nu e^c_{\lambda} - \{ \omega_{\nu}, (\partial_\rho \omega_{\lambda} + R_{\rho\lambda}) \}^{ab}_{\chi} \partial_\tau e^c_{\mu} \\
- (\partial_\tau \omega_{\mu} + R_{\tau\mu}) (\omega^{cd}_{\nu} \partial_\rho e^m_{\lambda} + ((\partial_\rho \omega_{\lambda} + R_{\rho\lambda}) e^m_{\nu}) \eta_{dm} \right] \eta_{cb}$$

(2.6)
and
\[
\{\alpha, \beta\}^{ab} = (\alpha^{ac}\beta^{db} + \beta^{ac}\alpha^{db})\eta_{cd}, \quad |\alpha, \beta|^{ab} = (\alpha^{ac}\beta^{db} - \beta^{ac}\alpha^{db})\eta_{cd} \tag{2.7}
\]

\[
D_\mu R^{ab}_\rho = \partial_\mu R^{ab}_\rho + (\omega_\mu^{ac}R^{db}_\rho + \omega_\mu^{bc}R^{da}_\rho) \tag{2.8}
\]

The complex conjugate \(e^{a\dagger}_\mu(x, \Theta)\) of the deformed tetrad fields is obtained from the hermitian conjugate of the relation (2.4):
\[
\hat{e}^{a\dagger}_\mu(x, \Theta) = e^{a\dagger}_\mu(x) + i\Theta^{\nu\rho}e^{a}_\nu(x) + \Theta^{\nu\rho}\Theta^{\alpha\beta}e^{a\rho\lambda\sigma}(x) + O(\Theta^3) \tag{2.9}
\]

and the real deformed metric is given by the formula [22):
\[
\hat{g}_{\mu\nu}(x, \Theta) = \frac{1}{2}\left[\hat{e}^{a\dagger}_\mu \cdot \hat{e}^{a\dagger}_\nu + \hat{e}^{a\dagger}_\nu \cdot \hat{e}^{a\dagger}_\mu\right]\eta_{ab} \tag{2.10}
\]

For the NC matrix, we took only space-space non-commutativity, \(\Theta_{0i} = 0\) (due to the known problem with unitary), so we choose the following NC parameter \(\Theta^{\mu\nu}\):
\[
\Theta^{\mu\nu} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & \Theta & 0 \\
0 & 0 & 0 & 0 \\
0 & -\Theta & 0 & 0
\end{pmatrix}, \quad \mu, \nu = 0, 1, 2, 3 \tag{2.11}
\]

where \(\Theta\) is a real positive constant.

The non-zero components of the NC tetrad fields \(\hat{e}_\mu^a\) are calculated in Ref. [24]. Then, using the definition (2.10), to obtain the non-zero components of the non-commutative metric \(\hat{g}_{\mu\nu}\) up to the second-order of \(\Theta:\)
\[
\hat{g}_{00} = -A^2(r) + \frac{\Theta^2}{16}\left\{A^2(r) - A(r)A'(r)(3 + 8rA'(r)) - 4A^2(r)(2A^2(r) + (1 + 5rA'(r))A''(r))
-4A^3(r)(A''(r) - rA'''(r))\right\} \sin^2(\theta) + O(\Theta^3) \tag{2.12}
\]
\[
\hat{g}_{11} = \frac{1}{A(r)} + \frac{\Theta^2}{16A^4(r)}\left\{27A^2(r) + A(r)A^2(r) + A(r)A''(r) - 9 + A(r)(-1 + 4A(r)))\right\} \sin^2(\theta) + O(\Theta^3) \tag{2.13}
\]
\[
\hat{g}_{12} = -\frac{\sin(2\theta)\Theta^2}{32A^3(r)}\left\{(6 + A(r)(11 + A(r)))A'(r) + r(-10 + A(r))A^2(r) + A(r)(5 + A(r)))\right\} + O(\Theta^3) \tag{2.14}
\]
\[
\hat{g}_{22} = r^2 + \frac{\Theta^2}{32A^4(r)}\left\{2\cos^2(\theta) + 4r(2 + \cos(2\theta))A(r) + A(r)(-12\cos^2(\theta) + r(-5 + \cos(2\theta))A'(r)
+2A^2(r)(9\cos^2(\theta) + r\sin^2(\theta)A'(r)(3 + 8rA'(r))) + 8A^3(r)\sin^2(\theta)(2A'(r) + rA''(r)))\right\} + O(\Theta^3) \tag{2.15}
\]
\[
\hat{g}_{33} = r^2\sin^2(\theta) + \frac{\Theta^2}{16A^2(r)}\left\{A^4(r)\sin^2(\theta) - 2A(r)(3\cos^2(\theta) + rA'(r)) + \cos^2(\theta)(1 + 6rA'(r))
+A^3(r)\sin^2(\theta)(-6 + 11rA'(r) + 12r^2A''(r)) + A^2(r)(9 + r\sin^2(\theta)(A'(r)(-27 + 16rA'(r))
-16rA''(r)))\right\} \sin^2(\theta) + O(\Theta^3) \tag{2.16}
\]

If we put \(\Theta \to 0\), we recover the commutative case (2.1), and in the equatorial plane \(\theta = \frac{\pi}{2}\), the diagonal form of the metric is obtained as in [24].
2.1 Geometrical propriety of Schwarzschild black hole in the NC spacetime

For the Schwarzschild metric we use this expression \( A(r) = \left(1 - \frac{2m}{r}\right)^{\frac{1}{2}} \), then we obtain the deformed Schwarzschild component \( \hat{g}_{00} \) with a correction up to the second order in \( \Theta \):

\[
-\hat{g}_{00} = \left(1 - \frac{2m}{r}\right) + \Theta^2 \left\{ m \left(88m^2 + mr \left(-77 + 15\sqrt{1 - \frac{2m}{r}}\right) - 8r^2 \left(-2 + \sqrt{1 - \frac{2m}{r}}\right)\right) \right\} \sin^2\theta + O(\Theta^3)
\]

(2.17)

We can similarly determine the other metric coefficients as \( \hat{g}_{00} \). As we see our expression depends on the angle \( \theta \), from now let’s call this the observation angle (or angle of the observer).

![Figure 1](image)

**Figure 1.** Behaviors of \( \hat{g}_{00} \) for a stationary observer at spatial infinity in the non-commutative spacetime with a given \( \Theta \).

In Fig.1, we show the influence of the NC parameter \( \Theta \) and the Observation angle \( \theta \) on the behaviors of \( \hat{g}_{00} \) as function of \( r \). As we see the non-commutativity shifted the singularity at the origin \( r = 0 \) to the finite radius \( r = 2m \) where we get a non-singular black hole, and this geometry increase the radii of the event horizon \( r_{NC}^H \gtrsim r_{C}^H \). The corresponding event horizon in the non-commutative Schwarzschild black hole can be obtain by solving \( \hat{g}_{00} = 0 \).

\[
r_{NC}^H = r_h \left[1 + \left(\frac{\Theta}{r_h}\right) \left(\frac{4\sqrt{5} + 1}{32\sqrt{3}}\right) \sin\theta + \left(\frac{\Theta}{r_h}\right)^2 \left(\frac{10 + \sqrt{5}}{128}\right) \sin^2\theta\right]
\]

(2.18)

where \( r_h = 2m \) is the event horizon of the Schwarzschild black hole in the commutative spacetime, this expression are depend the observation angle and that is schematized in the Fig. 2. As we see, the event horizon radii depend the observation angle \( \theta \) and that is look like the "Ergosphere" of Kerr black hole in the commutative spacetime [26 – 28], that has naturally emerged from the micro-structure of space-time itself. So the non-commutativity change the spherical symmetry of the black hole to the ellipse symmetry.

3 Thermodynamic propriety of the NC Schwarzschild black hole

The use of the thermodynamical approach in general relativity made us understand more about black holes. Therefore, the study of the nature and influence of the quantum structure

---

This document provides a detailed examination of the geometrical properties and thermodynamic aspects of non-commutative Schwarzschild black holes. It starts by discussing the formulation of the metric and the effects of non-commutativity on the geometry of the spacetime. The behaviors of the deformed metric components are analyzed with a focus on the influence of the observation angle. The document also explores the implications of non-commutativity on the event horizon radii, comparing them to the classical Schwarzschild case and highlighting the emergence of new geometrical structures such as the "Ergosphere." Finally, it delves into the thermodynamic properties, offering insights into how non-commutativity impacts the understanding of black holes. The content is rich with mathematical expressions and visual representations to aid in the comprehension of these complex physical phenomena.
of spacetime on the thermodynamics propriety is very important to understand better the physics of black holes. In which follows, we study the effect of the non-commutativity on the thermodynamics propriety of the NC Schwarzschild black hole.

In this direction, the usual first law of black hole thermodynamics in the NC spacetime can be written as:

\[ d\hat{M} = \hat{T}_H d\hat{S} + \hat{\Omega} d\hat{J} + \hat{\Phi} d\hat{Q} \]  

(3.1)

where \( \hat{M} \), \( \hat{T}_H \) and \( \hat{S} \) are the mass, the Hawking temperature, and entropy of the NC black hole, \( \hat{\Omega} \), \( \hat{J} \), \( \hat{\Phi} \) and \( \hat{Q} \) are respectively the angular velocity, angular momentum, the electrostatic potential, electric charge in the NC spacetime. As our problem is a non-charged and non-rotating black hole so the first law of thermodynamics reduces to:

\[ d\hat{M} = \hat{T}_H d\hat{S} \]  

(3.2)

### 3.1 Hawking temperature in the non-commutative spacetime

We have to make sure that, in the limit \( \Theta = 0 \) the NC expression of temperature reduce to the commutative expression. For that, the only choose satisfied this condition is given by:

\[ \hat{T}_H = \frac{1}{4\pi} \left| \frac{\partial g_{00}}{\partial r} \right|_{r=r_h^{NC}} \]  

(3.3)

using the NC correction to the event horizon radii (2.18), we get:

\[ \hat{T}_H \approx T_H \left[ 1 - \left( \frac{\Theta}{r_h} \right) \left( \frac{4\sqrt{5} + 1}{16\sqrt{5}} \right) \sin^2 \theta - \left( \frac{\Theta}{r_h} \right)^2 \left( \frac{10 + \sqrt{5}}{64} \right) \sin^2 \theta \right] \]  

(3.4)

For a massive black hole (a large one), then \( \Theta/r_h \ll 1 \), we recovers the the commutative Hawking temperature \( T_H \) for the Schwarzschild black hole.

\[ T_H = \frac{1}{4\pi r_h} \]  

(3.5)

As we see the expression of the corrected temperature (3.4) is dependent on observation angle \( \theta \), so the main radiation is not the same in all directions of the observer.

**Fig. 3**, show the behavior of the Hawking temperature of the NC Schwarzschild black hole as a function of event horizon radius. The result shows that the non-commutativity
removes the divergence of the Hawking temperature except for the poles ($\theta = 0, \pi$). In this scenario, the temperature of the NC Schwarzschild black hole increase during its evaporation to reach a maximum value $\hat{T}_H^{\text{max}} \approx 0.0426 \Theta \sin \theta$ at the critical size $r_h^{\text{crit}} \approx 1.085 \Theta \sin \theta$, then quickly fall to zero at the minimum size $r_h = r_h^0 \approx 0.598 \Theta \sin \theta$, at this point the black hole can not radiate anymore so is no processes of particle-antiparticle creation near the event horizon of the black hole with $r_h^0 \approx 0.598 \Theta \sin \theta$. The radiation of the black hole change to the negative temperature in the region $r_h < r_h^0$, in this region maybe a new quantum process is responsible for the negative behavior of the temperature. As we see, these physical quantities are dependent on the observational angle, so the radiation of the black hole is not the same in all directions of observation in the NC spacetime. In this fact, the two poles ($\theta = 0$ and $\theta = \pi$) of the NC black hole has a high temperature compared to the other directions and the small temperature can be measured by the observer in the equatorial plane $\theta = \frac{\pi}{2}$ (see Fig. 4), and this difference of poles-equator temperature increasing during the evaporation of the black hole. This result is similar to some models and observations of the difference of temperature between poles-equator of the sun in literature as in Ref. [29–32]. Add to this, the condition in the size of the black hole that stops radiating is different from observers to the others, except for the two poles, the black hole stays radiating. This new behavior of the radiation at the poles of the non-rotating black hole in the NC spacetime can be seen as a jet of the black hole, and that emerged from the NC effect of the spacetime.

The result in Fig. 4 shows an inversely gaussian distribution of the temperature of the Schwarzschild black hole in the NC spacetime. The difference between the poles and equator temperature is clear in the NC geometry, and the difference increases with the increase of the $\Theta$ also for the small black hole.

In order to get an estimation for the NC parameter $\Theta$, we take the information from the point when the black hole change its behavior of radiation (in the equatorial plane), the thermal energy at this point is proportional to the maximal temperature $\hat{T}_H^{\text{max}} \approx 0.0426 \Theta$ at the point $r_h^{\text{crit}} = 2m \approx 1.085 \Theta$. In the natural system of unity ($\hbar = k_B = c = 1$), the thermal energy can be writ as $E_{\text{th}} = \hat{T}_H^{\text{max}}$ and the total mass of the black hole $M = \frac{1}{2} r_h^{\text{crit}} \frac{1}{\Theta} \approx 0.5425 \Theta M_{\text{plack}}^2$. For a significant result, the thermal energy and the mass.
of the black hole should have the same order of magnitude at the critical point $r_{h}^{\text{crit}}$, from that the estimation of the NC parameter is:

$$\Theta \approx 2.257 \times 10^{-35} m \sim (1.39) l_{\text{Planck}}$$

(3.6)

This result is close to the one obtained in our previous work [24] and close to the result obtained in Ref. [11], and confirm that the NC propriety of the spacetime appears close to the Planck scale.

### 3.2 Non-commutative correction to the black hole entropy

The deformed expression of the entropy is depends on the area of the deformed black hole $A_{h}^{NC}$, which is given by:

$$\hat{S} = \frac{A_{h}^{NC}}{4}$$

(3.7)

The area of the NC Schwarzschild black hole can be calculated using the relation (2.18):

$$A_{h}^{NC} = 4\pi \left( r_{h}^{NC} \right)^{2}$$

$$\approx 4\pi r_{h}^{2} \left[ 1 + \left( \frac{\Theta}{r_{h}} \right) \left( \frac{4\sqrt{5} + 1}{16\sqrt{5}} \right) \sin\theta + \left( \frac{\Theta}{r_{h}} \right)^{2} \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right)^{2} \left( \frac{10 + \sqrt{5}}{64} \right) \sin^{2}\theta \right]$$

(3.8)

With the using of this expression the NC correction the entropy become:

$$\hat{S} = S_{H}^{C} \left[ 1 + \left( \frac{\Theta}{r_{h}} \right) \left( \frac{4\sqrt{5} + 1}{16\sqrt{5}} \right) \sin\theta + \left( \frac{\Theta}{r_{h}} \right)^{2} \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right)^{2} \left( \frac{10 + \sqrt{5}}{64} \right) \sin^{2}\theta \right]$$

(3.9)

When $\Theta/r_{h} \ll 1$, the commutative entropy of the Schwarzschild black hole is recovered:

$$S_{H}^{C} = \pi r_{h}^{2}$$

(3.10)
Figure 5. Behaviors of the non-commutative entropy of the Schwarzschild black hole as a function of the horizon radii $r_H$.

As we see in Fig. 5, there is a significant difference in the entropy variation between the commutative and NC spacetime $\Delta S = |\hat{S} - S_{CH}^C|$ in the situation of a small black hole, but for a large one, this difference becomes negligible. An important note, at the final stage of evaporation, the black hole stops radiating, but stay have a non-zero entropy (3.11), except in the two poles of the black hole and this can be explained by the quantum structure of spacetime.

$$\lim_{r_h \to 0} \hat{S} = \hat{S}_0 \approx \pi \Theta^2 \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right)^2 + \left( \frac{10 + \sqrt{5}}{64} \right) \sin^2 \theta$$ (3.11)

As we see this expression it’s emerged from a pure quantum effect of the spacetime itself, where this quantum effect his origin is the NC propriety of the spacetime. This entropy remnant indicates traces of the black hole that existed before it evaporated, as the entropy is related to the area of the black hole by the relation (3.7), then the black hole after evaporation stay have an area $A_{0NC} = 4\hat{S}_0$ which is a quantum area corresponding to the quantum entropy. This little strange quantum object has a quantum area and entropy but doesn’t have an event horizon, which can be seen as a microscopic remnant black hole.

Figure 6. Behaviors of the remnant entropy of the Schwarzschild black hole as a function of the observation angle $\theta$. 

– 9 –
Our result for the remnant entropy shows a Gaussian distribution in the final stage of the black hole evaporation \((r_h \approx 0)\) for different observation angles. When the maximum remnant entropy is in the equator \(\theta = \frac{\pi}{2}\) and disappear at the poles \(\theta = 0, \pi\). This gaussian structure is observed for considerable NC parameters \(\Theta\).

### 3.3 Gibbs free energy and the phase transition in the NC gauge theory

As a first step, we calculate the ADM mass of the black hole. This mass can be expressed as a function of the event horizon \(r_h\), by solved the equation \(\delta_{00}(r_{h}^{NC}) = 0\), so we get:

\[
\hat{M} = M \left[ 1 + \left( \frac{\Theta}{r_h} \right) \left( \frac{a(-3 + 128a^2)}{6 + 256a^2} \right) \sin \theta + \left( \frac{\Theta}{r_h} \right)^2 \left( \frac{3b + a^2(-3a^2 + 128)}{2(3 + 128a^2)} \right) \sin^2 \theta \right]
\]

where \(M = \frac{r_h}{2}\) is the ADM mass of the commutative Schwarzschild black hole, and \(a = \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right), \ b = \left( \frac{10 + \sqrt{5}}{128} \right)\).

**Figure 7.** Plot of the black hole mass with respect to the horizon radius \(r_h\).

Fig. 7 shows the behavior of the black hole mass as a function of the horizon radius. In the commutative case \(\Theta = 0\), the mass has linear comportment with the horizon radius \(M = r_h/2\) and vanishes at the origin, while in the NC spacetime the mass vanishes before the origin in the \(r_0^h\) (in this case the NC parameter \(\Theta\) play the role of the mass as we found in our previous work \([24]\)), and this radius increase with the increase of \(\Theta\). Where in the region \(r_h < r_0^h\) the mass of the black hole become negative, this behavior is responsible for the negative behavior of the temperature in Fig. 3.

#### 3.3.1 Heat capacity

We checking now the thermodynamics stability of the black hole by the signature of the heat capacity in the NC spacetime.

\[
\hat{C} = \left( \frac{\partial \hat{M}}{\partial \hat{T}_H} \right) = \left( \frac{\partial M}{\partial r_h} \right) \left( \frac{\partial \hat{T}_H}{\partial r_h} \right)^{-1}
\]

using the ADM mass (3.12) and the hawking temperature (3.4).
From Fig. 8, we plot the behaviors of the heat capacities of the Schwarzschild black hole in the NC spacetime. As we see for $\Theta = 0$ we get the standard heat capacities, which are always negative so does not exist a phase transition in the commutative Schwarzschild black hole. In the NC geometry, a small black hole $r_h < r_h^{crit}$ has positive heat capacities, so the system is in equilibrium, while the large one (massive black hole) has negative heat capacities which correspond to the system in non-equilibrium. The change of the heat capacities sign between negative and positive leads to the phase transition for Schwarzschild black hole in the NC spacetime at the size $r_h^{crit}$, where this point increase with the growth of the NC parameter $\Theta$ and the stable stage with positive heat capacity becomes large when $\Theta$ increases. Since our expression depends on the observation angle, then the phase transition is not the same in all directions of observation, where it begins from the equatorial and decrease the point condition $r_h^{crit}$ of the phase transition, then the stable stage with positive heat capacity becomes small and small when we close to the direction of two pols of this black hole.

### 3.3.2 Gibbs free energy

For more detail in the analysis of the phase transition, we need to investigate the Gibbs free energy, which is defined as the Legendre transform of the ADS mass:

$$\tilde{G} = \tilde{M} - \tilde{T}_H \tilde{S}$$

using the relation (3.4), (3.9) and (3.12) to plot $\tilde{G}$:

As we see in Fig. 9, the behavior of the Gibbs free energy has a minimum in the NC spacetime, which are determined by the solving this equation:

$$\frac{\partial \tilde{G}}{\partial r_h} = 0$$

Where the location of this minimum increase with $\Theta$ increase, then represents the stable region, and this result confirmed the one obtain in Fig. 8, which consists that the small black hole is stable compared to the large one. Add to this, the right panel shows the influence of the observation angle $\theta$, and the black hole rich the thermodynamics stability from the equator before other regions.

**Figure 8.** Plot the heat capacity of the black hole as function horizon radius $r_H^C$. 
The influence of the Hawking temperature on the Gibbs free energy are shown in Fig. 10, where we plot the expression (3.14) as a function of the commutative Hawking temperature $T_H$: 

$$T_H = T_{\tilde{H}}^{\max}$$

It can be seen in Fig. 10 (left panel) when the Hawking temperature of the black hole is considered the Gibbs free energy has two extremals (one stable and the other unstable), which can be obtained by solving the equation (3.15). From these behaviors, we show that the large black hole which corresponds to the maximum value of the Gibbs free energy is unstable thermodynamical when the stable one has minimal Gibbs free energy. Contrary to the commutative Schwarzschild black hole which is always unstable.

In Fig. 11 we represent the behavior of the Gibbs free energy as a function of the NC Hawking temperature with different values of the NC parameter $\Theta$. As we see in the NC spacetime the Gibbs’s free energy decrease rapidly (from the infinity at $\bar{T}_H \sim 0$) for the low temperature with a small $\Theta$. Then the Gibbs free energy changes its behavior to the increasing in slowly rate at $\bar{T}_H^{\max} \approx 0.0426/\Theta$ and the temperature bounces back when we increase in $\Theta$ this behavior change rapidly. Contrary to the commutative case $\Theta = 0$ the Gibbs free energy decrease with the increase of the Hawking temperature, and does not change her behavior. One can see that, this behavior is similar to the one obtained with the modified thermodynamic first law when the surface tension is considered as in Ref. [5, 6].
but in our work, this behavior emerged from the quantum structure of the spacetime in the modified Schwarzschild black hole by the non-commutativity with the usual first law of thermodynamic. From this analogy, we can see the non-commutativity as a tension of the spacetime at the quantum scale.

3.4 Pressure of the black hole in the NC spacetime

Our next step is motivated by the recent papers [33–35]. The authors of these papers suggest that quantum gravitational correction to the thermodynamics properties of the Schwarzschild black hole leads to pressure for these black holes, which is emerged from the quantum correction. Here we consider the quantum correction to the Schwarzschild black hole due to the NC gauge theory, so we add the pressure of the black hole to the first law of thermodynamic (3.2), to analyze the phase transition of the Schwarzschild black hole in the NC spacetime:

\[ d\hat{M} = \hat{T}_H d\hat{S} - \hat{P} d\hat{V} \]  

where \( \hat{V} \) denote the volume of the black hole in the NC spacetime:

\[
\hat{V} = \frac{4\pi}{3} (r_h^{NC})^3 \\
\approx \frac{4\pi}{3} r_h^3 \left[ 1 + 3 \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right) \left( \frac{\Theta}{r_h} \right) \sin\theta + 3 \left( \frac{\Theta}{r_h} \right)^2 \left( \frac{4\sqrt{5} + 1}{32\sqrt{5}} \right)^2 + \left( \frac{10 + \sqrt{5}}{128} \right) \right] \sin^2\theta
\]

\[ (3.17) \]
and $\hat{P}$ his conjugate the pressure of the NC black hole:

$$\hat{P} = -\left( \frac{\partial \hat{M}}{\partial \hat{V}} \right) = - \left( \frac{\partial \hat{M}}{\partial r_h} \right) \left( \frac{\partial \hat{V}}{\partial r_h} \right)^{-1}$$

$$\approx P \left[ 1 - 2a \left( \frac{\Theta}{r_h} \right) \sin \theta - 2 \left( \frac{\Theta}{r_h} \right)^2 \left( \frac{(64a^4 + 3b + 16a^2(-1 + 8b))}{(3 + 128a^2)} \right) \sin^2 \theta \right] \approx -P \left[ 1 - 2 \theta \left( \frac{\Theta}{r_h} \right) \sin \theta \right] - \left( \frac{\Theta}{r_h} \right)^2 \left( \frac{(64a^4 + 3b + 16a^2(-1 + 8b))}{(3 + 128a^2)} \right) \sin^2 \theta$$

where $P = -\frac{1}{8\pi r_h^2}$ is the commutative term of the pressure.

**Figure 12.** Plot the NC Pressure $\hat{P}$ of the black hole as function of the event horizon $r_h$.

As we see in Fig. 12, the non-commutativity give the pressure a new behaviors, where a minimum appear at the small size of the black hole, and the pressure change his behaviors during the evaporation of the black hole from the negative to the positive pressure. The pressure exerted by the large black hole on the spacetime is tiny, which is denoted by the negative pressure and this pressure decreasing during the evaporation of the black hole to rich the minimum, which is correspond to the maximum pressure exerted by the black hole on the spacetime (environment). This is due to an increase in the activity of the black hole emitting radiation (Hawking radiation), when the black hole reaches a maximum temperature (3), an increase in the pressure applied by the black hole on the spacetime will follow. When the radiation of the black hole decreasing (the temperature bounce back) this leads to decreasing in the pressure exerted on the spacetime. Then the effect is reversed, the pressure behavior change to the positive pressure for the small black hole, and that mean the spacetime exert a pressure on the black hole in his final stage of evaporation.

### 3.4.1 Gibbs free energy in presence of the black hole pressure

In this case the Gibbs free energy are defined as:

$$\hat{G} = \hat{M} - \hat{T}_H \hat{S} + \hat{V} \hat{P}$$

The influence of the pressure on the Gibbs free energy shows new behavior, as we see in Fig. 13. Where this function has three extremals, two correspond to the stable black hole and the other to the unstable one, for $\hat{T}_H^{\text{max}}$ and $0.028 \leq \hat{P} \leq 0.045$ in the NC spacetime (left panel). Note that, when we take a negative value of the pressure the Gibbs free energy shows the same behavior in Fig. 10 i.e. just two extremals of the Gibbs free energy where
The second corresponds to the intermediate black hole which is thermodynamically unstable. Where the size of the small, intermediate, and large black hole can be expressed by solving the equation (3.15) for \( r_h \). As we see (right panel), for fixed pressure \( \hat{P} = 0.028 \) and we change in the Hawking temperature \( 0.130 < T_H \leq \hat{T}_H^{\max} \) we conserved the same behavior of the Gibbs free energy i.e. three extremals, where we take \( T_H \leq 0.130 \) we get just one extreme. The behavior of Gibbs free energy for the Schwarzschild black hole including the pressure in the NC spacetime is similar to the one obtained in the AdS charged black hole in the commutative spacetime [36], then we can see that the non-commutativity play the same role as the charge of the black hole.

The behavior of the Gibbs free energy modified with the presence of the pressure is shown in Fig. 14, where we plot \( \hat{G} \) varying along with the function of the NC Hawking temperature for different fixed values of pressers. As we can see (left panel), for \( \hat{P} > 0 \), the
Gibbs free energy decreases rapidly (from infinity at $\hat{T}_H \approx 0$) as the temperature maximizes and when it bounces back, then the Gibbs free energy decreasing at a slow rate to established in the minimum values of the Gibbs free energy. For the negative pressure, $\hat{P} \leq 0$ we observe that the Gibbs free energy increases rapidly with the increase of the temperature, and when the Gibbs free energy reaches its maximum value started to decrease as the temperature maximizes, and when it bounces back the Gibbs free energy decreasing at a slow rate to established in the same minimum as for the positive pressure. Note that, when we increase in the opposite side of the pressure i.e $\hat{P} < 0$, we see the same behavior of the 'swallow tail' structure (that means two-phase coexist in the first order or can be seen as continuous phase transition?) in the literature [37–40] but in the NC spacetime the curves become smoother, except the critical point at $\hat{P}_c = -0.10$, where at this critical point the swallowtail structure disappears and an inflection point occurs, which is the second-order phase transition. When $\hat{P}\Theta_c$ this inflection point disappears. When $\hat{P} < \hat{P}_c$ the inflection point disappears.

![Figure 15](image.png)

**Figure 15.** The behaviors of the Gibbs free energy $\hat{G}$ as function of the NC Hawking temperature $\hat{T}_H$, for different NC parameter $\Theta$.

The Fig. 15 show the behavior of the Gibbs free energy as function of the NC Hawking temperature $\hat{T}_H$ and fixed pressure $\hat{P}$, for different $\Theta$. As we see, the swallow tail structure its appear at the small value of $\Theta$ with smoother curves, and this structure became small when $\Theta$ increase. At the critical point $\Theta_c = 0.31$ the swallow tail structure disappears and the inflection point occurs, and when $\Theta > \Theta_c$ this inflection point disappear. As we see this behavior is similar to the one obtained in Fig. 14 (right panel) but with the difference in the order of the structure of the curve, we can see that the NC parameter $\Theta$ play a similar role as the thermodynamical variable of the black hole.

### 4 Conclusions

In this work, we investigated in detail the thermodynamics propriety of the Schwarzschild black hole in the NC spacetime by using the Seiberg-Witten map. Our correction show a
new degree of freedom in this geometry in the deformed $\tilde{g}_{00}(r, \Theta, \theta)$. And some analysis of
the geometrical propriety of the black hole in this spacetime shows that the NC spreads the
singularity at $r = 0$ over a two-dimensional sphere of the radius $r = 2m$, where the new
event horizon is increasing by the non-commutativity of the spacetime $r_{h}^{NC} > r_{h}^{C}$. As we
have seen about the effect of the new variable, which made us reconsider the properties of
black holes, where we find that the event horizon of this black hole is not the same in all
directions of observation (see Fig. 1) and that looks like the ergosphere of the commutative
Kerr black hole, but in our work is emerged from the quantum structure of the spacetime.

In our discussion, we found that the non-commutativity of the spacetime modifies the
thermodynamics propriety of the Schwarzschild black hole. As a first step, we found the NC
temperature and this correction remove the divergence of the Hawking temperature, and
this led to the new maximum temperature which can be reached by the black hole during
its evaporation, then quickly fall to zero at a new minimum size of the black hole, where
the quantum effect of the non-commutativity is to cool down the black hole radiation in
his final stage. We noted that when we change in the observation angel $\theta$ the black hole
radiation changed, where the radiation increases as we go towards the poles of the black
hole, which can be seen as jet radiation from a non-rotating black hole, and that is an
effect of the quantum structure of the spacetime. Then we obtained the NC correction
to the entropy of this black hole, where this correction is negligible for the large black
hole but when the black hole evaporates and transit from the large to the small one this
correction become important. In the final stage when the black hole evaporated and stop
radiation $r_{h} \to 0$ (when $r_{h} < r_{h}^{C}$ the temperature became negative), but he stay have a
remnant entropy $S_{0}$ (see relation (3.11)). These results emerged from the quantum effect of
spacetime, where its origin is the non-commutativity of spacetime. This remnant entropy
led to the remnant surface $A_{0}^{NC}$, and this indicates the presence of a microscopic remnant
of the black hole. And this is a quantum object with the area and non-zero entropy, which
then are related to the quantum structure of the spacetime as the NC parameter $\Theta$ and the
observation angle $\theta$. The ADM mass and the heat capacity are also corrected. When the
ADM mass shows a new behavior, where mass vanishes before $r_{h}$ goes to zero, in this region
the mass became negative which is responsible for the negative temperature in this region.
Then our correction to the heat capacity shows a phase transition of the NC Schwarzschild
black hole, where the small black hole is thermodynamically stable but the large one is
unstable, and the large black hole evaporates and transit to the small one. We need to note
that, when we change the observational angle the size of the phase transition change, so
the phase transition of the black hole is not the same in all directions. In conclusion, the
non-commutativity give us a new scenario of the black hole evaporation, we summarize it
in some points:

- The evaporation of the black hole starts from the equator and goes up to the poles.
- After evaporation of the black hole, we get a quantum object with area and entropy,
  which can be seen as a microscopic remnant black hole.
- At the final stage of evaporation the physical quantities such as the temperature and
the ADM mass of the black hole can not be defined at $r_h = 0$.

Finally, a detailed analysis of the Gibbs free energy for the NC black hole shows two extremals one stable (the minimum) corresponding to the small black hole and the other unstable (maximum) for the large one, which confirmed the result obtained by the analysis of the heat capacity. Our result shows a phase transition of the Schwarzschild black hole and predicted a new scenario of the black hole evaporation and a microscopic remnant black hole. The including of the pressure due to the quantum correction of the non-commutativity show an intermediate region of the black hole (unstable region) between the large and the small one (stable). Where the small and the large ones are stable thermodynamically. Varying the value of pressure shows the swallowtail structure but the NC geometry makes the curves smoother and shows the inflection point at the critical value which means a second-order phase transition or continuous phase transition.
