Abstract

A simply laced Dynkin diagram gives rise to a family of curves over $\mathbb{Q}$ and a coregular representation, using deformations of simple singularities and Vinberg theory respectively. Thorne has conjectured and partially proven a strong link between the arithmetic of these curves and the rational orbits of these representations.

In this paper, we complete Thorne’s picture and show that 2-Selmer elements of the Jacobians of the smooth curves in each family can be parametrised by integral orbits of the corresponding representation. Using geometry-of-numbers techniques, we deduce statistical results on the arithmetic of these curves. We prove these results in a uniform manner. This recovers and generalises results of Bhargava, Gross, Ho, Shankar, Shankar and Wang.

The main innovations are: an analysis of torsors on affine spaces using results of Colliot-Thélène and the Grothendieck–Serre conjecture, a study of geometric properties of compactified Jacobians using the Białynicki-Birula decomposition, and a general construction of integral orbit representatives.

1 Introduction

1.1 Context

This paper is a contribution to arithmetic statistics of algebraic curves: given a family of curves $F$ over $\mathbb{Q}$, what can we say about the rational points of $C$ (or related objects) as $C$ varies in $F$? Over the last twenty years, Bhargava and his collaborators have made spectacular progress in this direction. One of their key ideas is that many arithmetic objects can be parametrised by rational or integral orbits of a representation $(G,V)$. When the representation is coregular, meaning that the ring of invariants $\mathbb{Q}[V]^G$ is a polynomial ring, they have developed powerful geometry-of-numbers techniques to count integral orbits of $V$. Combining orbit parametrisations with these counting techniques has led to many striking results; see [BS15a, BS15b, BS13a, BS13b, BG13, BGW17] for some highlights and [Ho14, Bha14b] for surveys of these results.

This raises the question: how does one find such orbit parametrisations? Typically they arise from classical algebro-geometric constructions. For example, elements of $\text{Sel}_2 E$ for an elliptic curve $E/\mathbb{Q}$ correspond to locally soluble genus-1 curves $C$ that are double covers of $\mathbb{P}^1_\mathbb{Q}$ [CFO08 §1.3], so give rise to $\text{PGL}_2(\mathbb{Q})$-orbits of binary quartic forms [BS15a Theorem 3.5]. This example goes back to Birch and Swinnerton-Dyer [BSD63] and has been used by Bhargava and Shankar to compute the average size of the 2-Selmer group of elliptic curves [BS15a]. See [BH16] for an exhaustive list of orbit parametrisations of genus-1 curves which are obtained using similar (but more difficult) algebro-geometric constructions. See also [BG13] for an orbit parametrisation of 2-Selmer groups of odd hyperelliptic curves using the geometry of pencils of quadrics [VAN13]. Even though these considerations have been hugely successful, Wei Ho writes that ‘Finding appropriate groups $G$ and vector spaces $V$ related to the Selmer elements is still a relatively ad hoc process’ [Ho14 p 45].

Gross [Gro11] observed that most coregular representation employed in arithmetic statistics arise from Vinberg theory, that is the theory of graded Lie algebras. This suggests the possibility to take Vinberg theory as a starting point, and to attempt to naturally construct families of curves in this setting. This is exactly the perspective taken in Thorne’s PhD thesis [Tho13] in the case of 2-Selmer groups. Given a simply laced Dynkin diagram of type $A, D, E$, he canonically constructs a family of curves and a coregular representation whose rational orbits should be related to the arithmetic of the curves in the family. This canonical construction unifies many orbit parametrisations in the literature and has already produced new results in arithmetic statistics; see [Tho15, RT18, Tho19]. However, to obtain all the expected consequences it remained to be shown that all elements of the 2-Selmer group give rise to rational orbits [Tho13 Conjecture 4.16] and that such rational orbits admit integral representatives.
The main goal of this paper is to resolve both these questions, and to do so in a uniform manner for all the ADE-families considered. By using geometry-of-numbers techniques developed by Bhargava and his collaborators, we obtain an upper bound on the average size of the 2-Selmer group of the Jacobians of the smooth curves in each family. This has consequences for the ranks of the Jacobians and the rational points of the curves in these families.

### 1.2 Statement of results

Let $D$ be a Dynkin diagram of type $A_n$, $D_n$ or $E_n$ and let $C \to B$ be the family of projective curves over $\mathbb{Q}$ with affine equation given by Table 1. For example, if $D = A_{2g}$, then $B = \text{Spec} \mathbb{Q}[p_2, \ldots, p_{2g+1}]$ and $C \to B$ is the family of all monic odd hyperelliptic curves of genus $g$. If $D = E_7$, then $C \to B$ is the family of all plane quartic curves with a marked rational flex point. The family $C \to B$ is a semi-universal deformation of its central fibre (by setting all coefficients $p_i$ equal to zero), which is a simple singularity of type $D$. (See Proposition 3.13.) We exclude the case $D = A_1$.

Write $B^{\text{rs}} \subset B$ for the locus above which $C \to B$ is smooth, the complement of a discriminant hypersurface. For every field $k/\mathbb{Q}$ and $b \in B^{\text{rs}}(k)$, write $J_b$ for the Jacobian of the smooth projective curve $C_b$, an abelian variety over $k$ of dimension equal to the genus of $C_b$. Our first main theorem is an orbit parametrisation for elements of $J_b(k)/2J_b(k)$.

To each diagram $D$ one may canonically associate a representation $V$ of a reductive group $G/\mathbb{Q}$. This construction, due to Thorne \cite{Tho13}, is recalled in \S 3.1 and is based on Vinberg’s theory of graded Lie algebras. See \S 3.2 for an explicit description of $G$ and $V$, although we will almost never use this description. The geometric quotient $V/G = \text{Spec} \mathbb{Q}[V]^G$ (parametrising $G$-invariant polynomials of $V$) turns out to be isomorphic to $B$. For every field $k/\mathbb{Q}$ and $b \in B(k)$, write $V_b$ for the subset of elements of $V$ which map to $b$ under the map $V \to V/G \simeq B$.

**Theorem 1.1** (Theorem 6.1). For every field $k/\mathbb{Q}$ and element $b \in B^{\text{rs}}(k)$, there exists an injection $\eta_b : J_b(k)/2J_b(k) \hookrightarrow G(k) \backslash V_b(k)$ compatible with base change.

See Theorem 6.4 for a more precise formulation and an explicit construction of this injection. Using a local-global principle for $G$, one can also embed the 2-Selmer group of $J_b$ inside the $G(\mathbb{Q})$-orbits of $V(\mathbb{Q})$. Recall that the 2-Selmer group of an abelian variety $A/\mathbb{Q}$ is a finite dimensional $\mathbb{F}_2$-vector space $\text{Sel}_2 A$ defined by local conditions and fitting inside an exact sequence

$$0 \to A(\mathbb{Q})/2A(\mathbb{Q}) \to \text{Sel}_2 A \to \text{III}(A/\mathbb{Q})/2] \to 0.$$  

**Theorem 1.2** (Corollary 6.3). For every $b \in B^{\text{rs}}(\mathbb{Q})$, the injection $\eta_b$ extends to an injection $\text{Sel}_2 J_b \hookrightarrow G(\mathbb{Q}) \backslash V_b(\mathbb{Q})$.
If \( D \) is of type \( A_2 \), \( C \rightarrow B \) is the family of elliptic curves in short Weierstrass form and we essentially recover the orbit-parametrisation of Birch–Swinnerton-Dyer [BSD63] used by Bhargava–Shankar [BS15a]. If \( D \) is of type \( A_{2g} \), we recover the orbit parametrisation of Bhargava and Gross [BG13].

Crucially, we additionally show that the \( G(\mathbb{Q}) \)-orbits corresponding to \( \text{Sel}_2 J_b \) using Theorem 1.2 have integral representatives away from small primes, see Corollary 7.20. Using geometry-of-numbers techniques to count integral orbits of \( V \), Theorem 1.2 may thus be used to give an upper bound on the average size of the 2-Selmer group of \( \text{Sel}_2 J_b \). Using the identification \( B = \text{Spec} \, \mathbb{Q}[p_{d_1}, \ldots, p_{d_m}] \) from Table 1 let \( F \) be the subset of elements \( b = (p_{d_1}(b), \ldots, p_{d_m}(b)) \in \mathbb{Z}^m \) with \( b \in B^m(\mathbb{Q}) \). We define the height of \( b \in F \) by the formula

\[
\text{ht}(b) := \max \left( |p_{d_1}(b)|^{1/d_1}, \ldots, |p_{d_m}(b)|^{1/d_m} \right).
\]

Note that for every \( X \in \mathbb{R}_{> 0} \), the set \( \{ b \in F \mid \text{ht}(b) < X \} \) is finite. To state the next theorem, note that each curve \( C_b \) has points at infinity not lying in the affine patch of Table 1 and we call those points the marked points. Their cardinality is displayed in Table 1.

**Theorem 1.3** (Theorem 9.1). Let \( m \) be the number of marked points. Then when ordered by height, the average size of the 2-Selmer group of \( J_b \) for \( b \in F \) is bounded above by \( 3 \cdot 2^{m-1} \). More precisely, we have

\[
\limsup_{X \to +\infty} \frac{\sum_{b \in F, \text{ht}(b) < X} \# \text{Sel}_2 J_b}{\# \{ b \in F \mid \text{ht}(b) < X \}} \leq 3 \cdot 2^{m-1}.
\]

The same result holds true even if we impose finitely many congruence conditions on \( F \). Assuming a certain plausible uniformity estimate (Conjecture 5.17), we show that the limit exists and the bound \( 3 \cdot 2^{m-1} \) is sharp, see §9.2. The constant \( 3 \cdot 2^{m-1} \) is consistent with the heuristics of Poonen and Rains [PR12], once we incorporate the fact that the \( m \) marked points give rise to a ‘trivial’ subgroup of \( \text{Sel}_2 J_b \) which has size \( 2^{m-1} \) most of the time (Proposition 9.4). See §1.3 for a comparison of this theorem with previously obtained results.

Bhargava and Shankar observed that bounding the 2-Selmer group gives an upper bound on the average rank of elliptic curves. In our case we can bound the average of the Mordell–Weil rank \( \text{rk}(J_b) \) of \( J_b \), the rank of the finitely generated abelian group \( J_b(\mathbb{Q}) \). Using the inequalities \( 2 \text{rk}(J_b) \leq 2 \text{rk}(J_b) \leq \# \text{Sel}_2 J_b \), we obtain:

**Corollary 1.4.** Let \( m \) be the number of marked points of the family \( C \rightarrow B \). Then when ordered by height, the average rank \( \text{rk}(J_b) \) where \( b \in F \) is bounded above by \( 3 \cdot 2^{m-2} \).

Theorem 1.3 has a number of interesting consequences for the rational points of \( C_b \), typically using various forms of the Chabauty–Coleman method. See for example [BG13, Corollary 1.4] and [PSL14] for such results in the case \( D = A_{2g} \), and [Lag20b, Corollary 1.3 & Theorem 1.4] in the case \( D = E_6 \). Theorem 1.3 should give similar such consequences for other \( D \).

### 1.3 Relation to other works

Theorem 1.3 has been previously obtained for many \( D \):

- \( A_2 \): Bhargava–Shankar [BS15a], who prove in this case that the average is exactly 3.
- \( A_{2g} \): Bhargava–Gross [BG13].
- \( A_{2g+1}, g \geq 2 \): Shankar–Wang [SW18].
We briefly describe the proof of Theorem 1.1, which is the first main novelty of this paper. Thorne has shown

We briefly mention the relation to our previous work [Lag20b], which treats the case

We describe what is new in this paper compared with Thorne’s work. He has shown the analogue of

\[ \delta \]

Then we may construct a

well-known lemma in arithmetic invariant theory (Lemma 2.13) shows that by twisting

\[ T \]

which

All these works combine geometry-of-numbers techniques with the orbit parametrisation of Theorem 1.2 and analysis of the representation \((G, V)\) requires specific arguments in each case. One of the main points of this paper is that we are able to prove Theorem 1.3 in a uniform way. Inspecting the above list, we see that the only cases not previously considered in the literature are \(D = D_{2g+2}\) with \(g \geq 2\), \(E_7\) and \(E_8\).

We describe what is new in this paper compared with Thorne’s work. He has shown the analogue of Theorem 1.1 for the subset of \(J_b(k)/2J_b(k)\) lying in the image of the Abel–Jacobi map \(C_b(k) \to J_b(k)/2J_b(k)\) with respect to a fixed marked point [Tho13, Theorem 4.15]. This allowed him and Beth Romano to deduce arithmetic-statistical results on the 2-Sehmer set of the curve \(C_b\) (a pointed subset of \(\text{Sel}_2 J_b\)) and the integral points of the affine curve \(C_b^0\), see [Tho15, Th18]. The first main innovation of this work is the construction of orbits associated with all elements of \(J_b(k)/2J_b(k)\), as was conjectured in [Tho13, Conjecture 4.16]. The second main innovation is an integral study of the representations \((G, V)\). In particular, we show that orbits arising from Theorem 1.2 admit integral representatives away from small primes (Theorem 1.3). This technical result is essential for applying orbit-counting methods and allows us to obtain new results on the arithmetic of the curves \(C_b\).

We briefly mention the relation to our previous work [Lag20b], which treats the case \(D = E_6\). The construction of orbits there relies on the isomorphism \(G_{sc} \simeq \text{Sp}_8\) (where \(G_{sc}\) is the simply connected cover of \(G\)) and the triviality of the Galois cohomology set \(H^1(k, \text{Sp}_8)\) for every field \(k\). However, this triviality fails to hold for general simply connected groups (for example, Spin groups), so the same argument does not work for all \(D\). Indeed, the proof of Theorem 1.1 explained in §1.4 is completely different from the one given in [Lag20b].

### 1.4 Method of proof

We briefly describe the proof of Theorem 1.1 which is the first main novelty of this paper. Thorne has shown that the stabiliser \(Z_G(v)\) of an arbitrary element \(v \in V_b(k)\) is canonically isomorphic to \(J_b[2]\), the 2-torsion subgroup of the Jacobian of \(C_b\). In fact, there always exists a distinguished orbit \(\kappa_0 \in G(k)\backslash V_b(k)\) and a well-known lemma in arithmetic invariant theory (Lemma 2.13) shows that by twisting \(\kappa_0\), the set \(G(k)\backslash V_b(k)\) can be identified with the pointed kernel of the map on Galois cohomology \(H^1(k, Z_G(\kappa_0)) \to H^1(k, G)\).

To prove Theorem 1.1 it therefore suffices to prove that the composition

\[
J_b(k)/2J_b(k) \xrightarrow{\delta} H^1(k, J_b[2]) \simeq H^1(k, Z_G(\kappa_0)) \to H^1(k, G),
\]

where \(\delta\) is the 2-descent map of \(J_b\), is trivial. We solve this problem by considering it universally. More precisely, a ‘categorified’ version of (1.4.1) associates to every element \(P \in J_b(k)\) a \(G\)-torsor \(T_P \to \text{Spec } k\) such that its isomorphism class \([T_P] \in H^1(k, G)\) equals the image of \(P\) under (1.4.1). This process can be carried out in a relative setting: let \(J^{rs}\) be the relative Jacobian of the family of smooth curves \(C|_{B^{rs}} \to B^{rs}\). Then we may construct a \(G\)-torsor \(T \to J^{rs}\) whose pullback along a point \(P\) : \(\text{Spec } k \to J^{rs}\) is isomorphic to \(T_P\). The crucial observation is that the geometry of the total space \(J^{rs}\) is very simple, despite the fibres of \(J^{rs} \to B^{rs}\) being abelian varieties so arguably not so simple. For example, \(J^{rs}\) is a rational variety. This fact (or rather a similar, more precise statement), together with an analysis of \(G\)-torsors on affine spaces and progress on the Grothendieck–Serre conjecture, allows us to prove \(J^{rs}\) admits a Zariski open cover above which \(T\) is trivial. This implies that each \(T_P\) is trivial, proving the theorem.
To analyse the geometry of $J^r$, we introduce a compactification of $J^r$ over the whole of $B$: there exists a projective scheme $\bar{J} \to B$ restricting to $J^r$ over $B^r$ called the \textit{compactified Jacobian} of $C \to B$. The scheme $\bar{J}$ parametrises rank-1 torsion-free sheaves following Altman–Kleiman [AK80], with the caveat that in the reducible fibres of $C \to B$ we have to impose a stability condition in the sense of Esteves [Est01] to obtain a well-behaved moduli problem. The main selling point of this paper can be summarised as follows: geometric properties of $\bar{J}$ are very useful in the construction of orbits associated with elements of $J^r$. For example, we show that even though the fibres of $\bar{J} \to B$ might be highly singular, $\bar{J}$ is a smooth and geometrically integral variety. Moreover, the Bialynicki-Birula decomposition from geometric representation theory shows that $\bar{J}$ has a decomposition into affine cells, so has a very transparent geometry. The consequences for the geometry of $J^r$ are strong enough to carry out the strategy of the previous paragraph and consequently prove Theorem 1.1. The smoothness of $\bar{J}$ is essential and follows from the fact that $C \to B$ is a semi-universal deformation of its central fibre.

The second main innovation of this paper is a uniform construction of integral representatives, and we again exploit the geometry of the compactified Jacobian. Most of the ideas were already present in our earlier work [Lag20b] which only treats the $E_6$ case. We achieve this by deforming to the case of square-free discriminant and using a general result on extending reductive group schemes over open dense subschemes of regular arithmetic surfaces (Lemma 7.12). We are able to deform to this case using Bertini theorems over $\mathbb{Q}_p$ and $\mathbb{F}_p$ and (again!) the smoothness of $\bar{J}$. Constructing integral orbits has often been a subtle point in the past, and we expect that our methods will have applications to settings different to the one considered here.

We say a few words about counting integral orbits of $V$. The geometry-of-numbers methods developed by Bhargava and his collaborators are fairly robust, so this part of the argument is rather formal and requires little new input. The only step that cannot be carried out uniformly is controlling orbits lying in the cuspidal region of the fundamental domain, the so-called ‘cutting of the cusp’. For every ADE diagram, this relies on combinatorial calculations in the associated root system. These calculations have appeared in the literature (on which we rely) except for the $D_{2g+2}$ case, which we handle explicitly in an appendix chapter. This is the only part of the paper where we rely on the previous works listed at the beginning of §1.3. It would be very interesting to find a less computational or even uniform proof for these calculations. This remark extends to other representations employed in arithmetic statistics, for example the ones used in [BS13a, BS13b]. See [BS13b, Table 2] for an example of the intricacies involved.

1.5 Other coregular representations

There are at least two ways in which coregular representations can arise from Vinberg theory that are not treated in this paper. In both cases, we expect that our methods go a long way towards proving analogous results to Theorem 1.3.

Firstly, one may try to incorporate gradings on nonsimply laced Lie algebras (so of type $B, C, F, G$) into the picture. Again there will be families of curves, but the relevant Selmer groups may arise from a general isogeny, not just multiplication by an integer. Such gradings have already appeared in the literature, implicitly and explicitly: a $\mathbb{Z}/2\mathbb{Z}$-grading on $G_2$ has been used to study 2-Selmer groups of elliptic curves with a marked 3-torsion point [BH13, Theorem 1.1(f)]; a $\mathbb{Z}/3\mathbb{Z}$-grading on $G_2$ has been used to study 3-isogeny Selmer groups of the curves $y^2 = x^3 + k$ [BES20]; a $\mathbb{Z}/2\mathbb{Z}$-grading on $F_4$ has been used to study 2-Selmer groups of a family of Prym surfaces [Lag20a].

Secondly, although their occurrence is more sporadic, there are also interesting $\mathbb{Z}/m\mathbb{Z}$-gradings on simple Lie algebras for $m \geq 3$; see for example [RT20], where the authors calculate the average size of the 3-Selmer group of the family of odd genus-2 curves using a $\mathbb{Z}/3\mathbb{Z}$-grading on $E_8$.

We mention that there are also coregular representations used in arithmetic statistics that do not arise from
Vinberg theory. The most important example is the representation \( \text{Sym}^2(n) \oplus \text{Sym}^2(n) \) of \( \text{SL}_n \), which is used in [BGW17] to show that a positive proportion of locally soluble hyperelliptic curves over \( \mathbb{Q} \) of fixed genus have no points over any odd degree extension. One feature that distinguishes this setting from ours is that their representation lacks a ‘Kostant section’, which is related to the fact that the curves they study do not come with specified marked points. We wonder if one can still interpret this representation in terms of Lie theory and study its arithmetic from this perspective.

1.6 Organisation

We now summarise the chapters of this paper. In §2 we recall some background results in Vinberg theory and arithmetic invariant theory. In §3 we recall the constructions and main results of Thorne’s thesis and introduce the Vinberg representation \((G,V)\) and family of curves \(C \to B\). In §4 we extend the results of Thorne’s thesis from the smooth fibres of \(C \to B\) to those fibres admitting at most one singular nodal point. In §5 we introduce and study compactified Jacobians of the family \(C \to B\). In §6 we analyse torsors on affine spaces and use this and our results from the previous chapters to prove Theorems 1.1 and 1.2 on the construction of orbits. In §7 we prove that such orbits admit integral representatives away from small primes. In §8 we employ Bhargava’s orbit-counting techniques and count integral orbits of the representation \((G,V)\). We combine all the results from the previous chapters in §9 to obtain Theorem 1.3. An appendix chapter, we perform some combinatorial calculations in the root system of type \(D_{2n}\) to complete the proof of Proposition 8.11 (cutting off the cusp) in this case. We note that the main novel contributions of this paper lie in Chapters 4, 5, 6 and 7.

1.7 Acknowledgements

This paper is a revised version of the author’s PhD thesis, written under the supervision of Jack Thorne. I would like to thank him for many useful suggestions, stimulating conversations and for carefully reading an early draft of this manuscript. Additionally, it is a pleasure to thank Alex Bartel, Jean-Louis Colliot-Thélène, Tom Fisher, Jesse Leo Kass and Beth Romano for interesting discussions related to the contents of this thesis.

1.8 Notation

1.8.1 General

For a field \(k\) we write \(k^s\) for a fixed separable closure and \(\Gamma_k = \text{Gal}(k^s/k)\) for its absolute Galois group.

If \(X\) is a scheme over \(S\) and \(T \to S\) a morphism we write \(X_T\) for the base change of \(X\) to \(T\). If \(T = \text{Spec} \, A\) is an affine scheme we also write \(X_A\) for \(X_T\).

If \(G\) is a smooth group scheme over \(S\) then we write \(H^1(S,G)\) for the set of isomorphism classes of étale sheaf torsors under \(G\) over \(S\), which is a pointed set coming from nonabelian Čech cohomology. If \(S = \text{Spec} \, R\) we write \(H^1(R,G)\) for the same object. If \(k\) is a field then \(H^1(k,G)\) coincides with the first nonabelian Galois cohomology set of \(G(k^s)\).

If \(G \to S\) is a group scheme acting on \(X \to S\) and \(x \in X(T)\) is a \(T\)-valued point, we write \(Z_G(x) \to T\) for the centraliser of \(x\) in \(G\). It is defined by the following pullback square:
Here $G \times_S X \to X \times_S X$ denotes the map $(g, x) \mapsto (g \cdot x, x)$ and $T \to X \times_S X$ denotes the composition of $x$ with the diagonal $X \to X \times_S X$.

If $V$ is a vector space over a field $k$ we write $k[V]$ for the graded algebra $\text{Sym}(V^\vee)$. Then $V$ is naturally identified with the $k$-points of the scheme $\text{Spec} \ k[V]$, and we call this latter scheme $V$ as well. If $G$ is a group scheme over $k$ acting on $V$ we write $V // G := \text{Spec} \ k[V]^G$ for the GIT quotient of $V$ by $G$.

1.8.2 Root lattices

We define a lattice to be a finitely generated free $\mathbb{Z}$-module $\Lambda$ together with a symmetric and positive-definite bilinear form $(\cdot, \cdot): \Lambda \times \Lambda \to \mathbb{Z}$. We write $\Lambda^\vee := \{ \lambda \in \Lambda \otimes \mathbb{Q} \mid (\lambda, \Lambda) \subset \mathbb{Z} \}$ for the dual lattice of $\Lambda$, which is naturally identified with $\text{Hom}(\Lambda, \mathbb{Z})$. We say $\Lambda$ is a root lattice if $(\lambda, \lambda)$ is an even integer for all $\lambda \in \Lambda$ and the set

$$\{ \alpha \in \Lambda \mid (\alpha, \alpha) = 2 \}$$

generates $\Lambda$. If $\Phi \subset \mathbb{R}^n$ is a simply laced root system then $\Lambda = \mathbb{Z}\Phi$ is a root lattice. In that case we define the type of $\Lambda$ to be the Dynkin type of $\Phi$.

If $S$ is a scheme, an étale sheaf of root lattices $\Lambda$ over $S$ is defined as a locally constant étale sheaf of finite free $\mathbb{Z}$-modules together with a bilinear pairing $\Lambda \times \Lambda \to \mathbb{Z}$ (where $\mathbb{Z}$ denotes the constant étale sheaf on $S$) such that for every geometric point $\bar{s}$ of $S$ the stalk $\Lambda_{\bar{s}}$ is a root lattice. In that case $\text{Aut}(\Lambda)$ is a finite étale $S$-group.

1.8.3 Reductive groups and Lie algebras

A reductive group scheme over $S$ is a smooth $S$-affine group scheme $G \to S$ whose geometric fibres are connected reductive groups. See [Spr09] for the basics of reductive groups over a field and [Con14] for reductive group schemes over a general base. A reductive group is assumed to be connected.

If $G, H, \ldots$ are algebraic groups then we will use gothic letters $\mathfrak{g}, \mathfrak{h}, \ldots$ to denote their Lie algebras. If $G$ is a reductive group with split maximal torus $T \subset G$, we shall write $\Phi_t \subset X^\vee(T)$ for the set of roots of $T$ in $\mathfrak{g}$, and $\Phi_t^\vee \subset X_+(T)$ for its set of coroots. The map $\alpha \in \Phi_t \mapsto d\alpha \in \text{Hom}(t, k)$ identifies $\Phi_t$ with the set of roots of $t$ in $\mathfrak{g}$, and we will use this identification without further comment.

If $x$ is an element of a Lie algebra $\mathfrak{g}$ then we write $Z_\mathfrak{g}(x)$ for the centraliser of $x$ in $\mathfrak{g}$, a subalgebra of $\mathfrak{g}$. We note that if $G$ is an algebraic group over a field $k$ and $x \in \mathfrak{g}$ any element, then the inclusion Lie $Z_G(x) \subset Z_\mathfrak{g}(x)$ is an equality if the characteristic of $k$ is zero or if $x$ is semisimple [Hum95, Proposition 1.10].
2 Background

2.1 The adjoint quotient of a Lie algebra

To motivate the results in Vinberg theory, we first recall some classical results in the invariant theory of Lie algebras.

Let $H$ be a connected reductive group over a field $k$ of characteristic zero with Lie algebra $h$. The group $H$ acts on $h$ via the adjoint representation. Let $p: h \to h//H = \text{Spec } k[h]^H$ be the so-called adjoint quotient induced by the inclusion $k[h]^H \subset k[h]$. We interpret $h//H$ as the space of invariants of the $H$-action on $h$ and $p$ as the morphism of taking invariants. Recall that an element $x \in h$ is said to be regular if $\dim z_h(x)$ is minimal among elements of $h$; this minimal value equals the rank of $H$. The subset of regular elements defines an open subscheme $h^\text{reg} \subset h$. The following classical proposition summarises the invariant theory of $h$.

**Proposition 2.1.**  

- Every semisimple element of $h$ is contained in a Cartan subalgebra, and if $k$ is algebraically closed every two Cartan subalgebras are $H(k)$-conjugate.

- Let $c \subset h$ be a Cartan subalgebra and let $W = N_H(c)/Z_H(c)$. Then the inclusion $c \subset h$ induces an isomorphism (the Chevalley isomorphism)

$$c//W \simeq h//H.$$ 

Since $W$ is a finite reflection group, this quotient is isomorphic to affine space.
• If $k$ is algebraically closed and $b \in (\mathfrak{h} \sslash H)(k)$, the fibre $p^{-1}(b)$ contains a unique open $H(k)$-orbit (consisting of the regular elements with invariants $b$) and a unique closed $H(k)$-orbit (consisting of the semisimple elements with invariants $b$).

We will often use induction arguments to reduce a statement for $\mathfrak{h}$ to a reductive Lie algebra of smaller rank. To this end, the following lemma will be helpful. We suppose for this lemma that $H$ is split and $T \subset H$ is a split maximal torus. This determines a root datum $(X^*(T), \Phi_t, X_*(T), \Phi_t^\vee)$ (in the sense of [Spr09 §7.4]) and a Weyl group $W = N_G(T)/T$.

**Lemma 2.2.** Let $x \in \mathfrak{t}$ be a semisimple element. Then the centraliser $Z_H(x)$ is a (connected) reductive group. Moreover, let

$$\Phi_t(x) = \{ \alpha \in \Phi_t | \alpha(x) = 0 \} \quad \text{and} \quad \Phi_t^\vee(x) = \{ \alpha^\vee \in \Phi_t^\vee | \alpha \in \Phi_t(x) \}.$$ 

Let $W_x = Z_W(x)$. Then the root datum of $Z_H(x)$ is $(X^*(T), \Phi_t(x), X_*(T), \Phi_t^\vee(x))$, and the Weyl group of $Z_H(x)$ with respect to $T$ is isomorphic to $W_x$.

**Proof.** The centraliser $Z_H(x)$ is connected by [Ste75 Theorem 3.14]. The fact that it is reductive and has the above root datum follows from [Ste75 Lemma 3.7]. The claim about the Weyl group of $Z_H(x)$ follows from [Ste75 Lemma 3.7(c)], again using the fact that $Z_H(x)$ is connected. 

Let $c \subset \mathfrak{h}$ a Cartan subalgebra. The discriminant polynomial $\Delta = k[\mathfrak{h}]^H$ is the image of the product of all the roots $\prod \alpha \in k[c]^W$ with respect to $c$ under the Chevalley isomorphism $k[c]^W \rightarrow k[\mathfrak{h}]^H$; it is independent of the choice of $c$. For $x \in \mathfrak{h}$ we have $\Delta(x) \neq 0$ if and only if $x$ is regular semisimple. The discriminant locus (or discriminant divisor) $D \subset \mathfrak{h} \sslash H$ is the zero locus of $\Delta$. This subscheme will play a fundamental role later in this paper (in particular in Chapter 4).

The next lemma says that the étale local structure of $\mathfrak{h} \sslash H$ and $D$ near a point is determined by the centraliser of a semisimple lift of that point.

**Lemma 2.3.** Let $x \in \mathfrak{h}$ be a semisimple element with centraliser $Z_{3\mathfrak{h}}(x)$. Let $c \subset \mathfrak{h}$ be a Cartan subalgebra containing $x$. Let $W$ and $W_x$ be the respective Weyl groups of $\mathfrak{h}$ and $Z_{3\mathfrak{h}}(x)$ with respect to $c$. Consider the diagram:

$$\begin{array}{ccc}
c & \rightarrow & c \\
\phi & \downarrow & \phi \\
\phi_x & \rightarrow & c \sslash W_x \rightarrow c \sslash W
\end{array}$$

Then $\psi$ is étale at $\phi_x(x)$. Moreover, if $D$ and $D_x$ denote the discriminant divisors of $\mathfrak{h}$ and $Z_{3\mathfrak{h}}(x)$ respectively, then $\psi^*D = D_x + R$, where $R$ is a divisor of $c \sslash W_x$ not containing $\phi_x(x)$ in its support.

**Proof.** We may assume that $k$ is algebraically closed and hence that $\mathfrak{h}$ is split. Since $\phi$ and $\phi_x$ are finite and faithfully flat (they are even Galois with Galois group $W$ and $W_x$), the map $\psi$ is finite and faithfully flat. The fact that $\psi$ is étale at $\phi_x(x)$ follows from the fact that the stabiliser of the $W$-action on $x$ is precisely $W_x$ (Lemma 2.2).

To prove the claim about the discriminant divisors, let $\Delta = \prod_{\alpha \in \Phi_x} \alpha \in k[c]^W$ and $\Delta_x = \prod_{\alpha \in \Phi_x(x)} \alpha \in k[c]^W_x$ denote the respective discriminant polynomials. By definition of $\Phi_x(x)$, $\Delta = \Delta_x \cdot R$ as elements of $k[c]^W_x$, where $R \in k[c]^W_x$ is a polynomial that does not vanish at $x$. Since $D$ and $D_x$ are the zero loci of $\Delta$ and $\Delta_x$ respectively, this proves the claim. 

[End of document.]
2.2 Vinberg theory

We keep the notations from §2.1. Let \( m \geq 1 \) be an integer. A \( \mathbb{Z}/m\mathbb{Z} \)-grading on \( \mathfrak{h} \) is, by definition, a direct sum decomposition

\[
\mathfrak{h} = \bigoplus_{i \in \mathbb{Z}/m\mathbb{Z}} \mathfrak{h}(i)
\]

into linear subspaces satisfying \([\mathfrak{h}(i), \mathfrak{h}(j)] \subset \mathfrak{h}(i+j)\). Given a \( \mathbb{Z}/m\mathbb{Z} \)-grading on \( \mathfrak{h} \), let \( \mathfrak{g} := \mathfrak{h}(0) \) and \( V := \mathfrak{h}(1) \). Then \( \mathfrak{g} \) is a subalgebra of \( \mathfrak{h} \) and the restriction of the adjoint representation of \( \mathfrak{h} \) induces an action of \( \mathfrak{g} \) on \( V \). If \( \zeta \in k \) is a primitive \( m \)-th root of unity, giving a \( \mathbb{Z}/m\mathbb{Z} \)-grading amounts to giving, by considering \( \zeta \)-eigenspaces, an automorphism \( \theta \) of \( \mathfrak{h} \) of order dividing \( m \). In general when no such \( \zeta \) exists or is fixed, giving a \( \mathbb{Z}/m\mathbb{Z} \)-grading amounts to giving a homomorphism \( \mu_m \to \operatorname{Aut}(\mathfrak{h}) \) of group schemes over \( k \).

Let \( \mu_m \to \operatorname{Aut}(H) \) be a morphism of group schemes. The composition \( \mu_m \to \operatorname{Aut}(H) \to \operatorname{Aut}(\mathfrak{h}) \) determines a \( \mathbb{Z}/m\mathbb{Z} \)-grading on \( \mathfrak{h} \). If \( G \) is the identity component of the centraliser of \( \mu_m \) in \( H \), then \( G \) has Lie algebra \( \mathfrak{g} \) and acts on \( V = \mathfrak{h}(1) \) by restriction of the adjoint action. The pair \((G,V)\) is called a Vinberg representation, and its study is dubbed Vinberg theory [Vin76]. If \( \mathfrak{h} \) is a semisimple \( \mathbb{Z}/m\mathbb{Z} \)-graded Lie algebra, a natural choice for \( H \) is the adjoint group \( \operatorname{Aut}(\mathfrak{h})^\circ \) of \( \mathfrak{h} \); this is the unique (up to nonunique isomorphism) connected semisimple group with trivial centre and Lie algebra \( \mathfrak{h} \).

We now summarise some of the highlights of Vinberg theory, referring to [Pan05, Lev09] for proofs. We call an element \( x \in V \) semisimple, nilpotent or regular if it is so when considered as an element of \( \mathfrak{h} \). We call a subspace \( \mathfrak{c} \subset V \) that consists of semisimple elements, that satisfies \([\mathfrak{c}, \mathfrak{c}] = 0\), and is maximal with these properties (among subspaces of \( V \)) a Cartan subspace.

**Lemma 2.4.** If \( x \in V \) has Jordan decomposition \( x = x_s + x_n \) where \( x_s, x_n \) are commuting elements that are semisimple and nilpotent respectively, then \( x_s, x_n \in V \).

**Proposition 2.5.** Every semisimple \( x \in V \) is contained in a Cartan subspace of \( V \). Every two Cartan subspaces are \( G(k^\times) \)-conjugate.

We call a triple \((e, h, f)\) an \( \mathfrak{sl}_2 \)-triple of \( \mathfrak{h} \) if \( e, h, f \) are nonzero elements of \( \mathfrak{h} \) satisfying the following relations:

\[
[h,e] = 2e, \quad [h,f] = -2f, \quad [e,f] = h.
\]

The classical Jacobson–Mozorov lemma states that every nilpotent element in \( \mathfrak{h} \) can be completed to an \( \mathfrak{sl}_2 \)-triple. If \( \mathfrak{h} \) is \( \mathbb{Z}/m\mathbb{Z} \)-graded, we say an \( \mathfrak{sl}_2 \)-triple is normal if \( e \in \mathfrak{h}(1) \), \( h \in \mathfrak{h}(0) \) and \( f \in \mathfrak{h}(-1) \).

**Lemma 2.6** (Graded Jacobson–Mozorov). Every nilpotent \( e \in \mathfrak{h}(1) \) is contained in a normal \( \mathfrak{sl}_2 \)-triple \((e, h, f)\).

**Proof.** See [KR71] Proposition 4], which only treats the case \( m = 2 \) but whose proof works for any \( m \). (We will only need the \( m = 2 \) case in this paper.)

The next proposition describes the basic geometric invariant theory of the representation \((G,V)\). Let \( \pi: V \to V / G = \operatorname{Spec} k[V]^G \) be the graded analogue of the adjoint quotient from §2.1.

**Proposition 2.7.** • Let \( \mathfrak{c} \subset V \) be a Cartan subspace and \( W(\mathfrak{c}) := N_G(\mathfrak{c})/Z_G(\mathfrak{c}) \). Then the inclusion \( \mathfrak{c} \subset V \) induces an isomorphism

\[
\mathfrak{c} \cap W(\mathfrak{c}) \simeq W(\mathfrak{c}) \simeq V / G.
\]

The group \( W(\mathfrak{c}) \) is a finite pseudo-reflection group, so the quotient is isomorphic to affine space.
- If \( k \) is algebraically closed and \( b \in (V \sslash G)(k) \), then the fibre \( \pi^{-1}(b) \) contains a unique closed \( G(k) \)-orbit, the set of semisimple elements with invariants \( b \).

**Remark 2.8.** In contrast to the \( m = 1 \) case, it is not true in general that two regular element \( x, y \in V(k) \) with the same invariants (that is, with the same image in \( V \sslash G \)) are \( G(k) \)-conjugate. Indeed, it follows from Proposition 3.8 below that the \( \mathbb{Z}/2\mathbb{Z} \)-gradings introduced in \( \S 3.1 \) can have multiple \( G(k) \)-orbits of regular nilpotent elements.

### 2.3 Stable gradings

We keep the notations of \( \S 2.1 \) and \( \S 2.2 \). Of particular interest to us are the stable gradings.

**Definition 2.9.** Suppose that \( k \) is algebraically closed. We say a vector \( v \in V \) is **stable** (in the sense of geometric invariant theory) if the \( G \)-orbit of \( v \) is closed and its stabiliser \( Z_G(v) \) is finite. We say \((G, V)\) is **stable** if \( V \) contains stable vectors. If \( k \) is not necessarily algebraically closed, we say \((G, V)\) is stable if \((G_k^+, V_k^+)\) is.

Stable gradings of simple Lie algebras over an algebraically closed field of characteristic zero have been classified \([RLY12, \S 7.1, \S 7.2]\) in terms of regular elliptic conjugacy classes of (twisted) Weyl groups. In the case of involutions (in other words, \( \mathbb{Z}/2\mathbb{Z} \)-gradings), this classification takes the simple form of Lemma 2.10, see \([Tho13, \text{Lemma 2.6}]\) for a proof. We say two involutions \( \theta, \theta': H \to H \) are \( H(k) \)-conjugate if there exists an \( h \in H(k) \) such that \( \theta' = h \theta h^{-1} \).

**Lemma 2.10.** Suppose that \( k \) is algebraically closed. Then there exists a unique \( H(k) \)-conjugacy class of stable involutions.

For example, if \( H \) is a torus then the only stable involution is given by the inversion map \( h \mapsto h^{-1} \).

One of the main advantages of stable gradings is that they have a particularly good invariant theory. The next proposition describes this more precisely in the case of \( \mathbb{Z}/2\mathbb{Z} \)-gradings. In particular, it shows that regular semisimple orbits over algebraically closed fields are well understood. We refer to \([Tho13, \S 2]\) for precise references.

**Proposition 2.11.** Suppose that \( \theta: H \to H \) is a stable involution, with associated Vinberg representation \((G, V)\). Then the following properties are satisfied:

1. Let \( \mathfrak{c} \subset V \) be a Cartan subspace and \( W(\mathfrak{c}) := N_G(\mathfrak{c})/Z_G(\mathfrak{c}) \). Then \( \mathfrak{c} \) is a Cartan subalgebra of \( \mathfrak{h} \) and the map \( N_G(\mathfrak{c}) \to W_\mathfrak{c} := N_H(\mathfrak{c})/Z_H(\mathfrak{c}) \) is surjective. Consequently, the inclusions \( \mathfrak{c} \subset V \subset \mathfrak{h} \) induce isomorphisms

   \[ \mathfrak{c} \sslash W_\mathfrak{c} \simeq V \sslash G \simeq \mathfrak{h} \sslash H. \]

   In particular, the quotient is isomorphic to affine space.

2. Suppose that \( k \) is algebraically closed and let \( x, y \in V(k) \) be regular semisimple elements. Then \( x \) is \( G(k) \)-conjugate to \( y \) if and only if \( x, y \) have the same image in \( V \sslash G \).

3. Let \( \Delta \in \mathbb{Q}[V]^G \) be the restriction of the Lie algebra discriminant of \( \mathfrak{h} \) to the subspace \( V \) and suppose that \( k \) is algebraically closed. Then for all \( x \in V(k), \) \( x \) is regular semisimple if and only if \( \Delta(x) \neq 0 \), if and only if \( x \) is stable in the sense of Definition 2.9.
2.4 Arithmetic Invariant Theory

Let $k$ be a field with separable closure $k^s$. Let $G/k$ be a smooth algebraic group acting on a $k$-vector space $V$. In general, a fixed $G(k^s)$-orbit in $V(k^s)$ might break up into multiple $G(k)$-orbits, and the study of this phenomenon is referred to as arithmetic invariant theory [BG14]. We recall its relation to Galois cohomology, which lies at the basis of the orbit parametrisations in this paper.

**Lemma 2.12.** Suppose that $G$ acts on a $k$-scheme $X$. Suppose that the $k$-point $e \in X(k)$ has smooth stabiliser $Z_G(e)$ and that the action of $G(k^s)$ on $X(k^s)$ is transitive. Then there is a natural bijection

$$G(k) \backslash X(k) \simeq \ker(H^1(k, Z_G(e)) \rightarrow H^1(k, G)).$$

**Proof.** This is [BG14 Proposition 1]. The bijection is explicitly constructed as follows: if $x \in X(k)$, transitivity ensures that there exists an element $g \in G(k^s)$ with $x = g \cdot e$. For every element $\sigma \in \Gamma_k = \text{Gal}(k^s/k)$, we again have $x = \sigma(g) \cdot e$, so the map $\sigma \mapsto g^{-1}\sigma(g)$ defines a 1-cocycle with values in $Z_G(e)$ which is trivial in $H^1(k, G)$. \qed

In fact, we will need a relative version of Lemma 2.12 which is valid over any base scheme.

**Lemma 2.13.** Let $G \rightarrow S$ be a smooth affine group scheme acting on an $S$-scheme $X$. Let $e \in X(S)$ be an $S$-point and suppose that the action map $m: G \rightarrow X, g \mapsto g \cdot e$ is smooth and surjective. Then the assignment $x \mapsto \text{isomorphism class of the } Z_G(e)\text{-torsor } m^{-1}(x)$ induces a bijection between the set of $G(S)$-orbits of $X(S)$ and the kernel of the map of pointed sets $H^1(S, Z_G(e)) \rightarrow H^1(S, G)$.

**Proof.** This is [Con14 Exercise 2.4.11]: the conditions imply that $X \simeq G/Z_G(e)$ and since $G$ and $Z_G(e)$ (the fibre above $e$ of the smooth map $m$) are $S$-smooth we can replace fppf cohomology by étale cohomology. \qed

2.5 The Grothendieck–Serre conjecture

We discuss some general results concerning principal bundles over reductive group schemes which will be useful in §6. Recall from [Con14 Definition 3.1.1] that a reductive group scheme over $S$ is a smooth $S$-affine group scheme $G \rightarrow S$ whose geometric fibres are connected reductive groups.

**Definition 2.14.** Let $R$ be a regular local ring with fraction field $K$ and let $G \rightarrow \text{Spec } R$ be a reductive group scheme. We say that the Grothendieck–Serre conjecture holds for $R$ and $G$ if the restriction map

$$H^1(R, G) \rightarrow H^1(K, G)$$

is injective.

Note that the injectivity $H^1(R, G) \rightarrow H^1(K, G)$ is stronger than requiring that this map has trivial kernel, since this is merely a map of pointed sets. It is conjectured that the Grothendieck-Serre conjecture holds for every reductive group scheme over every regular local ring; see [Pan18] for a survey and [Ces21 §1.4] for a short summary of known results. Below we will single out the known cases that we will need.

**Lemma 2.15.** Let $X$ be a regular integral scheme with function field $K$. Let $G$ be a reductive $X$-group scheme. Suppose that the Grothendieck-Serre conjecture holds for all local rings of $X$ and $G$. Then every two $G$-torsors over $X$ that are generically isomorphic (that is, isomorphic over $K$) are Zariski locally isomorphic (that is, isomorphic after restricting to a Zariski open cover).
Proof. Let $T,T'$ be two $G$-torsors over $X$ which are generically isomorphic and let $x \in X$. We need to prove that $x$ has an open neighbourhood over which $T$ and $T'$ are isomorphic. Since the Grothendieck-Serre conjecture holds for the local ring $\mathcal{O}_{X,x}$, the torsors $T$ and $T'$ are isomorphic when restricted to $\text{Spec}\, \mathcal{O}_{X,x}$. The result follows from spreading out this isomorphism.

Proposition 2.16. Let $R$ be a regular local ring and $G$ a reductive $R$-group. Suppose that at least one of the following is satisfied:

- $R$ is a discrete valuation ring;
- $R$ contains an infinite field.

Then the Grothendieck-Serre conjecture holds for $R$ and $G$.

Proof. The case of a discrete valuation ring was proved by Nisnevich [Nis84], with corrections by Guo [Guo20]. The case where $R$ contains an infinite field was proved by Fedorov and Panin [FP15].

The conjecture is known in many other cases; see [Ces21] for a recent general result when $R$ is of mixed characteristic and [Pan17] for the case where $R$ contains a finite field.

Corollary 2.17. Let $X$ be a regular integral scheme and $G$ a reductive $X$-group. Suppose that at least one of the following conditions is satisfied:

- $X$ is a Dedekind scheme;
- $X$ has a map to the spectrum of an infinite field.

Then every two $G$-torsors over $X$ that are generically isomorphic are Zariski locally isomorphic.

Proof. Combine Lemma 2.15 and Proposition 2.16.

3 Around Thorne’s thesis

In the remainder of this paper we will focus on a particular Vinberg representation. Given a Dynkin diagram of type $A,D,E$, we will canonically construct a stable $\mathbb{Z}/2\mathbb{Z}$-grading on the Lie algebra of the corresponding type following Thorne’s thesis [Tho13, §2]. We then recall and extend some of its basic properties in §3.2–3.6. In §3.7 we introduce the corresponding family of curves $C \to B$ and in §3.8 we recall the relation between stabilisers in $V$ and the 2-torsion in the Jacobians of smooth fibres of $C \to B$. We do not claim any originality in this chapter, except maybe for some of the calculations in §3.9.

3.1 A split stable $\mathbb{Z}/2\mathbb{Z}$-grading

Let $H$ be a split adjoint simple group of type $A,D,E$ over $\mathbb{Q}$ with Dynkin diagram $D$. We have an exact sequence

$$1 \to H \to \text{Aut}(H) \to \text{Aut}(D) \to 1. \quad (3.1.1)$$
Assume that $H$ is equipped with a pinning $(T, P, \{X_\alpha\})$. By definition, this means that $T \subseteq H$ is a split maximal torus (which determines a root system $\Phi_H := \Phi_t$), $P \subseteq H$ is a Borel subgroup containing $T$ (which determines a root basis $S_H \subseteq \Phi_H$), and $X_\alpha$ is a generator for each root space $h_\alpha$ for $\alpha \in S_H$. The subgroup $\text{Aut}((H, T, P, \{X_\alpha\})) \subset \text{Aut}(H)$ of elements preserving the pinning determines a splitting of the sequence (3.1.1).

On the other hand, if $W = N_H(T)/T$ denotes the Weyl group of $\Phi_H$, we have an exact sequence

$$1 \to W \to \text{Aut}(\Phi_H) \to \text{Aut}(D) \to 1.$$ (3.1.2)

We define $\vartheta \in \text{Aut}(H)$ as the unique element of $\text{Aut}((H, T, P, \{X_\alpha\}))$ whose image in $\text{Aut}(D)$ under (3.1.1) coincides with the image of $-1 \in \text{Aut}(\Phi_H)$ in $\text{Aut}(D)$ under (3.1.2). Note that $\vartheta = 1$ if and only if $-1 \in W$.

Write $\tilde{\rho} \in X_\rho(T)$ for the sum of the fundamental coweights with respect to $S_H$, characterised by the property that $(\alpha \circ \tilde{\rho})(t) = t$ for all $\alpha \in S_H$. Let

$$\theta := \vartheta \circ \text{Ad}(\tilde{\rho}(-1)) = \text{Ad}(\tilde{\rho}(-1)) \circ \vartheta.$$ Then $\theta$ defines an involution of $h$ and thus by considering $(\pm 1)$-eigenspaces it determines a $\mathbb{Z}/2\mathbb{Z}$-grading

$$h = h(0) \oplus h(1).$$

Let $G := (H^\theta)\circ$ be the identity component of the centraliser of $\theta$ in $H$ and let $V := h(1)$. The space $V$ defines a representation of $G$ by restricting the adjoint representation. If we write $g$ for the Lie algebra of $G$ then $V$ is a Lie algebra representation of $g = h(0)$. The Vinberg representation $(G, V)$ is a central object of study of this paper. Its relevance can be summarised in the following proposition, proved in [Tho16 Proposition 1.9].

**Proposition 3.1.** Up to $H(\mathbb{Q})$-conjugacy, $\theta$ is the unique involution of $H$ with the property that $\theta$ is stable (Definition 2.1) and the reductive group $G$ is split over $\mathbb{Q}$.

The first property of Proposition 3.1 is geometric: it characterises the $H(\mathbb{Q})$-conjugacy class of $\theta$. The second property is arithmetic, and it is equivalent to requiring the existence of a regular nilpotent in $V(\mathbb{Q})$. (For the last claim, see [Tho13 Corollary 2.15].) Note that in our construction of $\theta$ the element $E = \sum_{\alpha \in S_H} X_\alpha$ is a regular nilpotent in $V(\mathbb{Q})$.

Write $B := V // G = \text{Spec} \mathbb{Q}[V]^G$ and $\pi : V \to B$ for the natural quotient map. We have a $G_m$-action on $V$ given by $\lambda \cdot v = \lambda v$ and there is a unique $G_m$-action on $B$ such that $\pi$ is $G_m$-equivariant. The invariant theory of the pair $(G, V)$ is summarised in Proposition 2.11. We additionally record the following fact concerning the smooth locus of $\pi$, which follows from the proof of [Tho13 Proposition 3.10].

**Lemma 3.2.** Let $x \in V$ and let $d\pi_x$ be the induced map on tangent spaces $T_x V \to T_{\pi(x)} B$. Then $d\pi_x$ is surjective if and only if $x$ is regular. Consequently, the smooth locus of $\pi$ coincides with $V^{\text{reg}} := V \cap h^{\text{reg}}$.

### 3.2 Explicit determination of $(G, V)$

Using the results of [Ree10] applied to the Kac diagram of $\theta$ [RLYG12 §7.1, §7.2] (or an explicit description of $\theta$ in the case of classical groups), one may calculate the isomorphism class of the split group $G$ and the representation $V$ explicitly. These results are summarised in Table 3 where we have used the following notation:

- If $G$ is defined as a subgroup of $\text{GL}_n$, then $(n)$ denotes the representation of $G$ corresponding to this embedding.
We treat the

We will only need these explicit identifications in the proof of Proposition 8.11. Moreover we will calculate

The normalised Kac coordinates of \( \theta \)

The component group

\( H \)

be verified explicitly or follow from \([\text{Ric}82, \text{Lemmas 5.1 and 5.3}]\). It follows that

Firstly, we use Weyl groups. Recall that \( W_H = N_H(T)/T \) denotes the Weyl group of \( H \). We know that \( T^\theta = T^\theta \) is a maximal torus of \( G \), and moreover the centraliser \( Z_H(T^\theta) \) of \( T^\theta \) equals \( T \); these claims can be verified explicitly or follow from \([\text{Ric}82 \text{ Lemmas 5.1 and 5.3}]\). It follows that \( N_H(T^\theta) \subset N_H(T) \), so \( W_{H^\theta} := N_{H^\theta}(T^\theta)/T^\theta \) is naturally a subgroup of \( W_H \). Let \( W_G := N_G(T^\theta)/T^\theta \) be the Weyl group of \( G \), a normal subgroup of \( W_{H^\theta} \). We have inclusions \( W_G \subset W_{H^\theta} \subset W_H \).

We will only need these explicit identifications in the proof of Proposition 8.11. Moreover we will calculate

The normalised Kac coordinates of \( \theta \). Since the highest root has coordinate \( 0 \), we obtain a diagram of type \( A_7 \). Moreover, the representation \( V \) has highest weight the fundamental weight corresponding to \( \alpha_4 \), so is isomorphic to \( \Lambda^4(8) \), where \( (8) \) denotes the defining representation of \( \text{SL}_8 \).

We treat the \( E_7 \) case as an example. The extended Dynkin diagram is given by:

\[
\begin{array}{c}
\cdots \\
\alpha_0 \\
\alpha_1 \\
\alpha_2 \\
\alpha_3 \\
\alpha_4 \\
\alpha_5 \\
\alpha_6 \\
\alpha_7 \\
\cdots
\end{array}
\]

The normalised Kac coordinates of \( \theta \) (given in \([\text{RLYG12} \text{ §7.1, Table 4}]\)) are everywhere zero, except at the bottom node \( \alpha_2 \), which has coordinate 1. We may now apply the results of \([\text{Ree10} \text{ §2.4}]\). Since the Kac coordinates are invariant under the automorphism of the extended diagram, the component group of \( H^\theta \) is of order 2. Since the highest root has coordinate 2 at \( \alpha_2 \), the centre of \( G \) is of order 2. If we delete the node \( \alpha_2 \), we obtain a diagram of type \( A_7 \), so \( G \) semisimple is of type \( A_7 \). Since \( G \) is split, it follows that \( G \cong \text{SL}_8/\mu_4 \). Moreover, the representation \( V \) has highest weight the fundamental weight corresponding to \( \alpha_4 \), so is isomorphic to \( \Lambda^4(8) \), where \( (8) \) denotes the defining representation of \( \text{SL}_8 \).

3.3 The component group of \( H^\theta \)

The group \( H^\theta \) is typically disconnected, and we have a tautological exact sequence

\[
1 \to G \to H^\theta \to \pi_0(H^\theta) \to 1.
\]

The component group \( \pi_0(H^\theta) \) is a finite étale group scheme over \( \mathbb{Q} \). We will show that \( \pi_0(H^\theta) \) is split and describe it in two different ways, which will be useful in the proof of Proposition 6.10.

Firstly, we use Weyl groups. Recall that \( W_H = N_H(T)/T \) denotes the Weyl group of \( H \). We know that \( T^\theta = T^\theta \) is a maximal torus of \( G \), and moreover the centraliser \( Z_H(T^\theta) \) of \( T^\theta \) equals \( T \); these claims can be verified explicitly or follow from \([\text{Ric}82 \text{ Lemmas 5.1 and 5.3}]\). It follows that \( N_H(T^\theta) \subset N_H(T) \), so \( W_{H^\theta} := N_{H^\theta}(T^\theta)/T^\theta \) is naturally a subgroup of \( W_H \). Let \( W_G := N_G(T^\theta)/T^\theta \) be the Weyl group of \( G \), a normal subgroup of \( W_{H^\theta} \). We have inclusions \( W_G \subset W_{H^\theta} \subset W_H \)."
Lemma 3.3. The inclusion \( N_{H^\theta}(T^\theta) \subset H^\theta \) induces an isomorphism \( W_{H^\theta}/W_G \simeq \pi_0(H^\theta) \).

Proof. This is implicit in the proof of [Ree10 Lemma 3.9]; we sketch the details. It suffices to prove that \( H^\theta = G \cdot N_{H^\theta}(T^\theta) \). This can be checked on geometric points, so let \( k/\mathbb{Q} \) be an algebraically closed field and \( h \in H^\theta(k) \). The conjugate subgroup \( \text{Ad}(h) \cdot T^\theta \) is a maximal torus of \( G_k \). Since \( G_k \) is reductive, \( G(k) \) acts transitively on its maximal tori, so \( \text{Ad}(h) \cdot T^\theta = \text{Ad}(g) \cdot T^\theta \) for some \( g \in G \). We see that \( g^{-1}h \in N_{H^\theta}(T^\theta) \), as claimed.

Corollary 3.4. The finite étale \( \mathbb{Q} \)-group \( \pi_0(H^\theta) \) is constant (in other words, has trivial Galois action) and the map \( H^\theta(\mathbb{Q}) \to \pi_0(H^\theta) \) is surjective.

Proof. It suffices to prove the latter claim. Since \( T \) is a maximal torus of \( H, W_H \) is a constant group scheme, so its subgroup \( W_{H^\theta} \) is constant too. By Lemma 3.3 it suffices to show that \( N_{H^\theta}(T^\theta)(\mathbb{Q}) \to W_{H^\theta} \) is surjective. This follows from Hilbert’s theorem 90 since the torus \( T^\theta \) is \( \mathbb{Q} \)-split.

For the second description, choose a Cartan subspace \( \mathfrak{c} \subset V \) and let \( C \subset H \) be the maximal torus with Lie algebra \( \mathfrak{c} \). Since \( \theta \) acts as \(-1\) on \( \mathfrak{c} \) it acts via inversion on \( C \) hence \( C[2] \subset H^\theta \). The next lemma is [KR71 Proposition 1]:

Lemma 3.5. We have \( H^\theta = G \cdot C[2] \). In other words, the inclusion \( C[2] \subset H^\theta \) induces a surjection \( C[2] \to \pi_0(H^\theta) \).

Lemma 3.5 allows us to give an explicit description of \( \pi_0(H^\theta) \).

Corollary 3.6. Let \( H_{sc} \to H \) be the simply connected cover of \( H \) and let \( \pi_1(H) \) denote the centre of \( H_{sc} \). Then there is an isomorphism \( \pi_0(H^\theta) \simeq \pi_1(H)/2\pi_1(H) \).

Proof. Let \( C \subset H \) be a maximal torus whose Lie algebra is a Cartan subspace of \( V \). (Such a torus certainly exists: take the centraliser of a regular semisimple element of \( V \).) Let \( C_{sc} \subset H_{sc} \) be its preimage in \( H_{sc} \). We have an exact sequence

\[
1 \to \pi_1(H) \to C_{sc} \to C \to 1.
\]

(3.3.1)

Examining the long exact sequence associated with the 2-torsion of (3.3.1) shows that

\[
\frac{C[2]}{\text{image}(C_{sc}[2] \to C[2])} \simeq \pi_1(H)/2\pi_1(H).
\]

We claim that the left-hand-side is isomorphic to \( \pi_0(H^\theta) \). Indeed, the involution \( \theta: H \to H \) uniquely extends to an involution of \( H_{sc} \), still denoted by \( \theta \), and a theorem of Steinberg [Ste68 Theorem 8.1] shows that \( H_{sc}^\theta \) is connected. It follows that the induced map \( H_{sc}^\theta \to H^\theta \) surjects onto \( G \). Therefore the kernel of the natural map \( C[2] \to \pi_0(H^\theta) \) (which is surjective by Lemma 3.5) agrees with the image of the map \( C_{sc}[2] \to C[2] \), as claimed.

3.4 The fundamental group of \( G \)

Proposition 3.7. The group \( G \) is semisimple and its fundamental group has order \( 2\#\pi_0(H^\theta) \).
Proof. Let \( H_{sc} \to H \) be the simply connected cover of \( H \) and let \( \pi_1(H) \) denote the centre of \( H_{sc} \). By a previously invoked theorem of Steinberg [Ste68, Theorem 8.1], \( H_{sc}^0 \) is connected. Therefore the induced map \( H_{sc}^0 \to G \) is surjective with kernel \( \pi_1(H)[2] \). Moreover \( \pi_1(H)[2] \) has cardinality \( #\pi_0(H^0) \) by Corollary 3.6. Hence it suffices to prove that \( H_{sc}^0 \) is semisimple and its fundamental group is of order 2. This is a result of Kaletha, see [Tho16, Proposition A.1].

### 3.5 Regular nilpotent elements in \( V \)

The next proposition describes the set of regular nilpotent elements in \( V \) [Tho13, Lemma 2.14].

**Proposition 3.8.** For every field \( k/\mathbb{Q} \), the group \( H^0(k) \) acts simply transitively on the set of regular nilpotent elements of \( V(k) \).

**Corollary 3.9.** Let \( k/\mathbb{Q} \) be a field and \( E \in V(k) \) a regular nilpotent. (For example, \( E = \sum_{a \in S_H} X_a \).) Then the map \( h \mapsto h \cdot E \) induces a bijection between \( \pi_0(H^0) \) and the set of \( G(k) \)-orbits of regular nilpotent elements in \( V(k) \).

**Proof.** Follows from Proposition 3.8 and the fact that \( H^0(k) \to \pi_0(H^0) \) is surjective (Corollary 3.4).

We see in particular that if \( H^0 \) is disconnected then there are multiple \( G \)-orbits of regular nilpotent elements in \( V \). To state the next result, recall from §2.2 the notion of a normal \( \mathfrak{s}\mathfrak{l}_2 \)-triple.

**Corollary 3.10.** Let \( k/\mathbb{Q} \) be a field and \( E \in V(k) \) a regular nilpotent element. Then \( E \) is contained in a unique normal \( \mathfrak{s}\mathfrak{l}_2 \)-triple.

**Proof.** Proposition 3.8 shows that the stabiliser \( Z_G(E) \) is trivial. Therefore the corollary follows from [Tho13, Lemma 2.17].

### 3.6 Kostant sections

We describe sections of the GIT quotient \( \pi : V \to B \) whose remarkable construction is originally due to Kostant. Let \( E \in V(\mathbb{Q}) \) be a regular nilpotent element and let \( (E, X, F) \) be the unique normal \( \mathfrak{s}\mathfrak{l}_2 \)-triple containing \( E \) using Corollary 3.10. We define the affine linear subspace \( \kappa_E := (E + \mathfrak{h}(F)) \cap V \subset V \). We call \( \kappa_E \) the Kostant section associated with \( E \), or simply a Kostant section.

**Proposition 3.11.** 1. The composition \( \kappa_E \hookrightarrow V \to B \) is an isomorphism.

2. \( \kappa_E \) is contained in the open subscheme of regular elements of \( V \).

3. The morphism \( G \times \kappa_E \to V, (g, v) \mapsto g \cdot v \) is étale.

**Proof.** Parts 1 and 2 are [Tho13, Lemma 3.5]; the last part is [Tho13, Proposition 3.4], together with the fact that \( G \times \kappa_E \) and \( V \) have the same dimension (apply [Tho13, Lemma 2.21] to \( x = 0 \)).

Every Kostant section \( \kappa_E \) determines a morphism \( B \to V \) that is a section of the quotient map \( \pi : V \to B \), and we denote this section by \( \kappa_E \) too. For any \( b \in B(k) \) we write \( \kappa_{E,b} \) for the fibre of \( \kappa_E \) over \( b \).
Definition 3.12. Let $k/\mathbb{Q}$ be a field and $v \in V(k)$. We say $v$ is $k$-reducible if $v$ is not regular semisimple or $v$ is $G(k)$-conjugate to $\kappa_{E,b}$ for some Kostant section $\kappa_E$ and where $b = \pi(v)$. Otherwise, we call $v$ $k$-irreducible.

If $k$ is algebraically closed, then every element of $V(k)$ is $k$-reducible by Proposition 2.11.

3.7 A family of curves

If $k/\mathbb{Q}$ is a field, an element $v \in \mathfrak{h}(k)$ is called subregular if $\dim \mathfrak{z}_v(x) = r + 2$, where $r$ is the rank of $\mathfrak{h}$. By [Tho13, Proposition 2.27], the vector space $V$ contains subregular nilpotent elements; let $e \in V(\mathbb{Q})$ be such an element and fix $(e, x, f)$ a normal $\mathfrak{sl}_2$-triple extending it, using Lemma 2.6.

Slodowy [Slo80] has shown that the restriction of the invariant map $(e + \mathfrak{z}_v(f)) \to B$ is a family of surfaces. Moreover, he has shown that this family is a semi-universal deformation of its central fibre, which is a simple surface singularity of the type corresponding to that of $H$. Proposition 3.13 is a $\mathbb{Z}/2\mathbb{Z}$-graded analogue of Slodowy’s result, due to Thorne. Define $C^o := (e + \mathfrak{z}_v(f)) \cap V$. Restricting the invariant map $\pi : V \to B$ to $C^o$ defines a morphism $\varphi : C^o \to B$.

Proposition 3.13. 1. The geometric fibres of $\varphi$ are reduced connected curves.

2. The central fibre $C^o_0 = \varphi^{-1}(0)$ has a unique singular point which is a simple singularity of type $A_r, D_r, E_r$, corresponding to that of $H$.

3. We can choose coordinates $p_{d_1}, \ldots, p_{d_r}$ on $B$ where $p_{d_i}$ is homogeneous of degree $d_i$ and coordinates $(x, y, p_{d_1}, \ldots, p_{d_{r-1}})$ on $C^o$ such that $C^o \to B$ is given by the affine equation of Table 1.

4. The formal completion of $C^o \to B$ along its central fibre defines a morphism of formal schemes $\widehat{C^o} \to \widehat{B}$ which is a semi-universal deformation of its central fibre.

5. The morphism $\varphi$ is faithfully flat. It is smooth at $x \in C^o$ if and only if $x$ is a regular element of $V$.

6. The action map $G \times C^o \to V$, $(g, x) \mapsto g \cdot x$ is smooth.

Proof. This is proved in Thorne’s thesis. The first three parts are [Tho13, Theorem 3.8]; for the definition of a simple curve singularity, see [Tho12, End of §2]. The fourth part follows from the fact that the semi-universal deformation of an isolated hypersurface singularity can be explicitly computed [Slo80, §2.4] and agrees with the equations given in Table 1. The last two parts are contained in [Tho13, Proposition 3.4 and Proposition 3.10].

The next lemma describes the singularities of the fibres of $C^o \to B$ very precisely; see [Tho13, Corollary 3.16] for its proof.

Lemma 3.14. Let $k/\mathbb{Q}$ be a field, $b \in B(k)$ and $v \in V_b(k)$ a semisimple element. Then there is a bijection between the connected components of the Dynkin diagram of $Z_H(v)$ and the singularities of $C^o_b$, which takes each (connected, simply laced) Dynkin diagram to a singularity of the corresponding type.

We compactify the flat affine family of curves $C^o \to B$ to a flat projective family of curves $C \to B$ as described in [Tho13, Lemma 4.9]. That lemma implies that the complement $C \setminus C^o$ is a disjoint union of sections $\infty_1, \ldots, \infty_m : B \to C$ and $C \to B$ is smooth in a Zariski open neighbourhood of these sections. For every field $k/\mathbb{Q}$ and $b \in B(k)$, the curve $C_b$ has $k$-rational points $\infty_{1,b}, \ldots, \infty_{m,b} \in C_b(k)$; we call these the marked points of $C_b$. 

21
Lemma 3.15. There are natural bijections between:

1. The sections $\infty_1, \ldots, \infty_m$ of $C \to B$;
2. Irreducible components of $C_0$;
3. $G$-orbits of regular nilpotent elements of $V$ whose closure contains $e$.

The bijections are given as follows: given a section $\infty_i$, map it to the irreducible component containing $\infty_i,0 \in C_0$; given an irreducible component of $C_0$, map it to the $G$-orbit of any point on its smooth locus.

Proof. See [Tho13] Lemma 4.14] and its proof. \(\square\)

For the remainder of this paper, we fix a section $\infty_1 = \infty$ of $C \to B$ and a regular nilpotent element $E \in V(\mathbb{Q})$ whose $G$-orbit corresponds to $\infty$ under Lemma 3.15. Moreover, we fix a choice of polynomials $p_d, \ldots, p_d \in \mathbb{Q}[V]^G$ and coordinates $x, y$ of $C^\circ$ satisfying the conclusions of Proposition 3.13. Recall that we have defined a $G_m$-action on $B$ which satisfies $\lambda \cdot p_d = \lambda^d p_d$. There exist unique positive integers $a, b$ such that $\lambda \cdot (x, y, p_d, \ldots, p_{d-1}) := (\lambda^d x, \lambda^b y, \lambda^{2d} p_d, \ldots, \lambda^{2d} \cdot p_{d-1})$ defines a $G_m$-action on $C$ and such that the morphism $C \to B$ is $G_m$-equivariant with respect to the square of the usual $G_m$-action on $B$. (The integers $(a, b)$ are given by $(w_r, w_{r+1})$ in the table of [Tho13] Proposition 3.6. These weights can also be defined Lie theoretically, but we will not need this fact in what follows.)

3.8 Universal centralisers

Recall from the last paragraph of §3.7 that we have fixed a regular nilpotent $E \in V(\mathbb{Q})$; let $\kappa: B \to V$ be the Kostant section corresponding to $E$ constructed in §3.6. Recall from our conventions in §1.8 that if $v: S \to V$ is an $S$-point of $V$ then $Z_G(v) \to S$ denotes the centraliser of $v$ in $G$.

Definition 3.16. Let $Z \to B$ be the centraliser $Z_G(\kappa)$ of the Kostant section $\kappa: B \to V$ with respect to the $G$-action on $V$. Similarly, let $A \to B$ be the centraliser $Z_H(\kappa)$ of $\kappa: B \to \mathfrak{h}$ with respect to the $H$-action on $\mathfrak{h}$.

For every field $k/\mathbb{Q}$ and $b \in B(k)$, the group scheme $Z_b$ (respectively $A_b$) is the centraliser $Z_G(\kappa_b) \subset G$ of $\kappa_b$ in $G$ (respectively $Z_H(\kappa_b) \subset H$). We have $Z = A \cap (G \times B)$. Since $\kappa$ lands in the regular locus of $V$, $A$ and $Z$ are commutative group schemes. To state the next lemma, recall that $V^{\text{reg}} \subset V$ denotes the open subscheme of regular elements and that $\pi: V \to B$ and $\rho: \mathfrak{g} \to B$ denote the morphisms of taking invariants.

Lemma 3.17. Let $v: S \to V^{\text{reg}}$ be a morphism with $b = \pi(v) \in B(S)$. Then there is a canonical isomorphism $Z_G(v) \cong Z_b$. Similarly if $v: S \to \mathfrak{g}^{\text{reg}}$ is a morphism with invariants $b = p(v) \in B(S)$ then there is a canonical isomorphism $Z_H(v) \cong A_b$.

Proof. The isomorphism $Z_G(v) \cong Z_b$ follows from [Tho13] Proposition 4.1] and a very similar proof works for $A$; we briefly sketch it. The morphism $H \times B \to \mathfrak{g}^{\text{reg}}, (h, b) \mapsto h \cdot \kappa_b$ is smooth and surjective [Rie17] Lemma 3.3.1], so has sections étale locally. It follows that $v$ is $H$-conjugate to $\kappa_b$ étale locally on $S$. Conjugating defines isomorphisms $Z_H(v) \cong A_b$, again étale locally on $S$. Since $A_b$ is commutative, these isomorphisms do not depend on the choice of element by which we conjugate $v$ to $\kappa_b$. Using étale descent, these isomorphisms glue to give an isomorphism of group schemes $Z_H(v) \cong A_b$. \(\square\)

The next lemma gives a useful description of the fibres of $Z \to B$. I
Lemma 3.18. Let \( k/\mathbb{Q} \) be a field and \( x \in V(k) \) a regular element, with Jordan decomposition \( x = x_s + x_n \). Let \( c \subseteq V \) be a Cartan subspace containing \( x_s \) and let \( C \subseteq H \) denote the maximal torus with Lie algebra \( c \). Let \( H_{sc} \to H \) be the simply connected cover of \( H \) and \( C_{sc} \to C \) its restriction to \( C \). Then there is a canonical isomorphism

\[
\text{Hom}(Z_G(x), F_2) \simeq \text{image} \left( \frac{X^* (C)}{2X^* (C) + Z \Phi_c (x)} \to \frac{X^* (C_{sc})}{2X^* (C_{sc}) + Z \Phi_c (x)} \right). \tag{3.8.1}
\]

Proof. A theorem of Steinberg [Ste68, Theorem 8.1] shows that \((H_{sc})^0 \) is connected. Therefore \( Z_G(x) = \text{image}(Z_{(H_{sc})^0}(x) \to Z_{H^0}(x)) \). Now use [Tho13, Corollary 2.9].

Let \( B^{rs} \) denote the image of the subscheme regular semisimple elements in \( V \) under \( \pi : V \to B \). Then \( B^{rs} \) is also the complement of the discriminant locus \( (\Delta = 0) \) in \( B \), by Part 3 of Proposition 2.11. For a \( B \)-scheme \( X \), we denote its restriction to \( B^{rs} \) by \( X^{rs} \). The group scheme \( Z^{rs} \to B^{rs} \) is finite étale and \( A^{rs} \to B^{rs} \) is a family of maximal tori.

Definition 3.19. Let \( \Lambda \to B^{rs} \) be the character group of \( A^{rs} \).

In other words, \( \Lambda \) is the Cartier dual \( \text{Hom}(A^{rs}, \mathbb{G}_m) \) of \( A^{rs} \). The \( B^{rs} \)-scheme \( \Lambda \) is an étale sheaf of root lattices in the sense of §1.8.2. In particular, it comes equipped with a pairing \( \langle \cdot, \cdot \rangle : \Lambda \times \Lambda \to \mathbb{Z} \). This pairing induces an alternating pairing \( \langle \cdot, \cdot \rangle : \Lambda/2\Lambda \times \Lambda/2\Lambda \to F_2 \) which might be degenerate. Setting \( N_{\Lambda} := \text{image}(\Lambda/2\Lambda \to \Lambda^\vee/2\Lambda^\vee) \), we see [Tho13, Lemma 2.11] that \( \langle \cdot, \cdot \rangle \) descends to a nondegenerate pairing on \( N_{\Lambda} \). Lemma 3.18 implies:

Lemma 3.20. There exists a canonical isomorphism \( Z^{rs} \simeq N_{\Lambda} \).

We use the isomorphism of Lemma 3.20 to transport the pairing from \( N_{\Lambda} \) to \( Z^{rs} \): we thus obtain a nondegenerate pairing \( Z^{rs} \times Z^{rs} \to F_2 \).

It follows from Lemma 3.14 that the restriction \( C^{rs} \to B^{rs} \) is a family of smooth projective curves; write \( J^{rs} \to B^{rs} \) for the relative Jacobian of the family of smooth projective curves \( C^{rs} \to B^{rs} \) [BLR90, §9.3; Theorem 1]. The next result is one of the main results of Thorne’s thesis and a first step towards relating the curves \( C^{rs} \to B^{rs} \) to the representation \((G, V)\).

Proposition 3.21. There exists a canonical isomorphism \( J^{rs}[2] \simeq Z^{rs} \) of finite étale group schemes that sends the Weil pairing on \( J^{rs}[2] \) to the pairing on \( Z^{rs} \) defined above.

Proof. Since both group schemes are finite étale and \( B^{rs} \) is normal, it suffices to prove the statement above the generic point of \( B^{rs} \) by [Sta18, Tag 0BQM]. In that case the statement follows from [Tho13, Corollary 4.12].

Part 2 of Proposition 3.21 implies that the isomorphism \( J^{rs}[2] \simeq Z^{rs} \) is unique.

3.9 Monodromy of \( J^{rs}[2] \)

We give some additional properties of the group scheme \( J^{rs}[2] \to B^{rs} \), which by Lemma 3.20 and Proposition 3.21 we may identify with \( N_{\Lambda} \to B^{rs} \). Before we state them, we recall some definitions and set up notation.
Recall from [3.1] that \( T \) is a split maximal torus of \( H \) with Lie algebra \( t \) and Weyl group \( W \). Let \( L := X^*(T) \) be its character group and \( N_L := \text{image}(L/2L \to L'/2L') \). Consider the composition \( t \to t/W \xrightarrow{\sim} \mathfrak{h}/H \xrightarrow{\sim} V \smallsetminus G = B \), where \( t \to t/W \) is the natural projection, \( t/W \xrightarrow{\sim} \mathfrak{h}/H \) the Chevalley restriction isomorphism (Proposition 2.1), and \( \mathfrak{h}/H \xrightarrow{\sim} V \smallsetminus G \) is the isomorphism induced from the inclusion \( V \subset \mathfrak{h} \) (Proposition 2.11). Restricting to regular semisimple elements defines a finite étale cover \( H \) of \( \mathfrak{h} \).

**Proposition 3.22.** The finite étale group scheme \( J^{rs}[2] \to B^{rs} \) becomes trivial after the base change \( f : t^{rs} \to B^{rs} \), where it becomes isomorphic to the constant group scheme \( N_L \). The monodromy action is induced by the natural action of \( W \) on \( L \).

**Proof.** Since \( J^{rs}[2] \) is isomorphic to \( N_A \), it suffices to prove that the torus \( A \to B^{rs} \) is isomorphic to the constant torus \( T \times t^{rs} \to t^{rs} \) after pulling back along \( f \), with monodromy given by the action of \( W \) on \( T \).

To prove this, note that by Lemma [3.17] if \( x : S \to \mathfrak{h}^{rs} \) is an \( S \)-point with invariants \( b = p(x) \in B^{rs}(S) \), then \( Z_H(x) \simeq A_b \) as group schemes over \( S \). (Here \( \mathfrak{h}^{rs} \subset \mathfrak{h} \) denotes the subset of regular semisimple elements.) In particular, we can apply this to the \( t^{rs} \)-point \( f : t^{rs} \to \mathfrak{h}^{rs} \) (where \( i \) is the inclusion map), giving an isomorphism \( T \times t^{rs} \to A^\nu \). Since this isomorphism is induced by étale locally conjugating \( i \) to \( \kappa \) by elements of \( H \), the monodromy action is indeed given by the natural action of \( W \) on \( T \).

Proposition 3.22 shows that it suffices to understand the \( W \)-action on \( N_L \) if we wish to understand the group scheme \( J^{rs}[2] \). To this end, we perform some root system calculations in the following proposition.

**Proposition 3.23.** Suppose that \( H \) is not of type \( A_1 \).

1. \( L'/2L' \) has no nonzero \( W \)-invariant elements.

2. The \( \mathbb{F}_2[W] \)-representation \( N_L \) is absolutely irreducible, so every \( W \)-equivariant automorphism \( N_L \to N_L \) is the identity.

3. There exists an element \( w \in W \) that has no nonzero fixed points on \( N_L \).

**Proof.**

1. Note that \( L'/2L' = \text{Hom}(L/2L, \mathbb{F}_2) \), so let \( f : L/2L \to \mathbb{F}_2 \) be a nonzero \( W \)-invariant functional. If \( f \) vanishes on a root of \( L \), then \( f \) vanishes on all of them since they form a single \( W \)-orbit. Since the roots of \( L \) generate \( L/2L \), it follows that \( f(\alpha) = 1 \) for every root. Since we have assumed that \( L \) is not of type \( A_1 \), there exists roots \( \alpha, \beta \) such that \( \alpha + \beta \) is also a root. But then we would have \( 1 = f(\alpha + \beta) = f(\alpha) + f(\beta) = 1 + 1 = 0 \). This is a contradiction hence no such nonzero \( f \) exists.

2. Let \( S \subset N_L \otimes \mathbb{F}_2 \) be a \( W \)-stable subspace, and assume that \( v \in S \) is a nonzero element. Since the pairing \((\cdot, \cdot)\) on \( N_L \) is nondegenerate, there exists a root \( \alpha \in L \) such that \((v,\alpha) \ne 0 \) in \( \mathbb{F}_2 \). If \( w_\alpha \in W \) denotes the reflection associated with \( \alpha \), then \( w_\alpha(v) = v - (v,\alpha)\alpha \) also lies in \( S \). It follows that \( w_\alpha(v) - v = (v,\alpha)\alpha \) lies in \( S \) hence \( \alpha \) also lies in \( S \). Since \( W \) acts transitively on the roots, every root is contained in \( S \). Since the roots generate \( L \), it follows that \( S = N_L \otimes \mathbb{F}_2 \), as claimed. The second claim follows from Schur’s lemma. (We thank Beth Romano for helping us with the proof of this fact.)

3. We first consider the case that the pairing on \( L/2L \) is nondegenerate, which is equivalent to the projection map \( L/2L \to N_L \) being injective. Since \( L/2L \) and \( L'/2L' \) have the same order, the latter statement is also equivalent to the fact that \( L/2L \to L'/2L' \) is an isomorphism. We show that in this case it suffices to take a Coxeter element \( w_{\text{cox}} \) of \( W \). Indeed, let \( H_{sc} \to H \) be the simply connected cover of \( H \), let \( \pi_1 \) be the centre of \( H_{sc} \) and let \( T_{sc} \) be the preimage of \( T \) in \( H_{sc} \). It is a classical fact that
the inclusion $\pi_1 \subset T_{ac}$ restricts to an equality $\pi_1 = T_{ac}^{\text{wcox}}$, see [DW01] Theorem 1.6. Taking 2-torsion implies that $\pi_1[2] = T_{ac}[2]^{\text{wcox}}$. Since the map $L/2L \to L^\vee/2L^\vee$ is an isomorphism, the same is true for the map $T_{ac}[2] \to T[2]$ which has kernel $\pi_1[2]$, hence $T_{ac}[2]^{\text{wcox}} = \pi_1[2] = \{1\}$. Since $T_{ac}[2] \simeq L/2L$, we have shown that $(L/2L)^{\text{wcox}} = N_L^{\text{wcox}} = 0$, as claimed.

We now consider the general case. Let $S$ be a root basis of $L$, which is an $\mathbb{F}_2$-basis of the vector space $L/2L$. Since $L/2L \to N_L$ is surjective, there exists a subset $S_M \subset S$ projecting onto a basis of $N_L$. Let $M$ be the $\mathbb{F}_2$-span of $S_M$. Then $M$ is a (possibly reducible) root lattice associated with the sub-root system generated by $S_M$, and the composition $M/2M \to L/2L \to N_L$ is an isomorphism. The pairing $(\cdot, \cdot)$ on $L/2L$ restricts to a pairing on $M/2M$, and the previous sentence shows that this pairing on $M/2M$ is nondegenerate. It follows that $M$ is a direct sum of irreducible root lattices of the form considered in the first case of this proof. Let $w$ be a Coxeter element with respect to $S_M$, i.e. a product of the simple reflections in $S_M$. Then $(M/2M)^w = 0$ by the first case of the proof, so $N_L^w = 0$ too.

\[\square\]

4 The mildly singular locus

We keep the notations from Section 3.4. Recall from §3.3 that $B^{rs} \subset B$ denotes the locus where the discriminant polynomial $\Delta$ is nonzero, and that the family of curves $C \to B$ is smooth exactly above $B^{rs}$ (Lemma 3.14). In this chapter we introduce an open subset $B^1 \subset B$ strictly containing $B^{rs}$ where we allow the fibres of $C \to B$ to have one nodal singular point. We therefore call $B^1$ the ‘mildly singular locus’ of $B$. We then extend some results concerning the representation $V$ and the family of curves from $B^{rs}$ to $B^1$ in §4.2 and §4.3 and generalise Proposition 3.21 in §4.4. This will be useful for the construction of orbits in §6 and for the analysis of integral orbits of square-free discriminant in §7.4. To avoid stating the same assumption repeatedly, we will make the following assumption throughout the rest of this paper:

**Convention 4.1.** The group $H$ is not of type $A_1$.

4.1 The discriminant locus

Recall that we have fixed a maximal torus $T \subset H$ in §3.1. Recall from §2.1 that the discriminant polynomial $\Delta \in \mathbb{Q}[b]^H$ is the image of $\prod_{\alpha \in \Phi^+, \alpha \in \mathbb{Q}[t]}^\wedge$ under the isomorphism $\mathbb{Q}[i]^W \xrightarrow{\sim} \mathbb{Q}[b]^H$ of the Chevalley restriction theorem. Using the isomorphism $\mathbb{Q}[b]^H \xrightarrow{\sim} \mathbb{Q}[V]^G = \mathbb{Q}[B]$ from Proposition 2.11 we view $\Delta$ as an element of $\mathbb{Q}[B]$.

**Lemma 4.2.** For every field $k/\mathbb{Q}$, $\Delta$ is irreducible in $k[B]$.

**Proof.** It suffices to prove that we cannot partition $\Phi_t$ into two nonempty $W$-invariant subsets. Equivalently, we need to prove that $W$ acts transitively on $\Phi_t$. This is true since $\Phi_t$ is irreducible and simply laced. [\[\square\]]

We write $D$ for the subscheme of $B$ cut out by $\Delta$. Lemma 4.2 implies:

**Corollary 4.3.** The scheme $D$ is geometrically integral.

\[1\] The reference assumes that $T$ is a maximal torus in a compact Lie group, but this implies the corresponding result for a maximal torus in a semisimple group over a field of characteristic zero.
Write $D_{\text{sing}}$ for the singular locus of $D$, a closed subscheme of $D$.

**Definition 4.4.** We define $B^1$ as the complement of $D_{\text{sing}}$ in $B$; we call $B^1$ the mildly singular locus. We define $D^1$ as the complement of $D_{\text{sing}}$ in $D$.

The subscheme $B^1 \subseteq B$ is open and we have inclusions $B^{rs} \subseteq B^1 \subseteq B$. Since $D$ is geometrically integral, the complement of $B^1$ in $B$ has codimension $\geq 2$. (In fact, Lemma 3.3a shows that it has codimension exactly 2.) As a general piece of notation, if $X$ is a $B$-scheme we write $X^1$ for its restriction to $B^1$.

### 4.2 Representation theory over $B^1$

If $b$ is a point of $B$ we write $\mathfrak{h}_b$ for the fibre of the adjoint quotient $\mathfrak{h} \xrightarrow{p} \mathfrak{h}/H = B$ along this point.

**Lemma 4.5.** Suppose that $k/\mathbb{Q}$ is an algebraically closed field and $b \in B(k)$. Then $b \in D^1(k)$ if and only if some (equivalently, every) semisimple $x \in \mathfrak{h}_b(k)$ has the property that the derived subgroup of $Z_H(x)$ is of type $A_1$.

**Proof.** Since every two semisimple elements in $\mathfrak{h}_b(k)$ are $H(k)$-conjugate (Proposition 2.1), requiring the last claim for some semisimple element of $\mathfrak{h}_b(k)$ is equivalent to requiring it for all of them. Let $T \subseteq H$ be the fixed maximal torus of $\mathfrak{g}_t$ with root system $\Phi_t$ and Weyl group $W$. Let $x$ be an element of $t$ with invariants $b$. By Lemma 2.2 $Z_H(x)$ is a reductive group with root system $\Phi_t(x) = \{ \alpha \in \Phi_t \mid \alpha(x) = 0 \}$ and its Weyl group $W_x$ is the subgroup of $W$ generated by the reflections through $\Phi_t(x)$.

To prove the lemma, we need to prove that $b \in D^1(k)$ if and only if $\Phi_t(x)$ is of type $A_1$. Let $b_x$ be the image of $x$ in $t/W_x$ and let $D_x \subseteq t/W_x$ be the discriminant locus of $Z_H(x)$, with smooth locus $D_x^1$. By Lemma 2.3 $D_x \to D$ is etale at $b_x$ hence $b \in D^1(k)$ if and only if $b_x \in D_x^1(k)$. So it suffices to prove that $b_x \in D_x^1(k)$ if and only if $\Phi_t(x)$ is of type $A_1$.

Firstly, suppose that $\Phi_t(x) = \{ \alpha, -\alpha \}$ is of type $A_1$, so $W_x = \{ 1, w_\alpha \}$ is generated by the reflection through $\alpha$. Then one can compute $D_x$ explicitly: $t/W_x$ is given, up to taking a product with an affine space, by the quotient of $\text{Spec } k[X]$ by the $\mathbb{Z}/2\mathbb{Z}$-action $X \mapsto -X$. This quotient is $\text{Spec } k[X^2]$ and $D_x$ is the vanishing locus of $X^2$, hence $D_x$ is smooth. Therefore $b_x \in D_x^1(k)$, which proves one direction.

Conversely, suppose that $\Phi_t(x)$ is not of type $A_1$. If $\Phi_t(x)$ were empty then $b \in B^{rs}(k)$, so $\Phi_t(x)$ is nonempty and of rank $\geq 2$. We need to prove that $D$ is singular at $b$. Since the singular locus of $D$ is closed and $x$ is the specialisation of a point $y$ for which the rank of $\Phi_t(y)$ is exactly 2, we may assume that $\Phi_t(x)$ is either of type $A_2$ or $A_1 \times A_1$. In both cases, one can compute explicitly that $D_x$ is not smooth at $b_x$, as required.  

Recall from Proposition 3.1a that if $k/\mathbb{Q}$ is a field and $b \in B^{rs}(k)$, we have an isomorphism $Z_b \simeq J_b[2]$ of finite étale $k$-groups. So if $g$ denotes the common arithmetic genus of the curves $C_b$, the group scheme $Z_b$ has order $2^{2g}$.

**Lemma 4.6.** If $b \in D^1(k)$, the group scheme $Z_b$ has order $2^{2g-1}$.

**Proof.** The group scheme $Z_b$ is the centraliser of the element $\kappa_b$, which is regular by Proposition 3.1a. By Lemma 3.1b it suffices to prove that if $L$ is a root lattice of the same type as $H$, $N_L = \text{image}(L/2L \to L'/2L')$ and $\alpha \in L$ is a root, then $\alpha$ is nonzero in $N_L$. Since $L$ is not of type $A_1$ (Convention 4.1), there exists a root $\beta$ with $(\alpha, \beta) = -1$. Therefore $\alpha \not\in 2L'$, so $\alpha$ is nonzero in $N_L$, as claimed.

Before we state the last result of this section, we record a useful lemma.
Lemma 4.7. Let $k/\mathbb{Q}$ be a field and $x \in h(k)$ a semisimple element with centraliser $L := Z_H(x)$. Then the centre of $L$ is connected.

Proof. We may assume that $k$ is algebraically closed and that $x$ lies in $t(k)$, the Lie algebra of the maximal torus $T \subset H$ fixed in §3.1. It suffices to prove that the character group of the centre of $L$ is torsion-free. By Lemma 2.2 this group can be identified with $X^*(T)/Z_{\Phi_1}(x)$. Since $H$ is adjoint, $X^*(T) = Z_{\Phi_1}$. The definition of the root system $\Phi_1(x)$ shows that it is $\mathbb{Q}$-closed in the sense of [Slo80 §3.5]. By [Slo80 Proposition 3.5], every root basis of $\Phi_1(x)$ can be extended to a root basis of $\Phi_1$. This implies that $Z_{\Phi_1}(x)$ is a direct summand of $Z_{\Phi_1}$ so the quotient $Z_{\Phi_1}/Z_{\Phi_1}(x)$ is indeed torsion-free. 

To state the next proposition, recall that $V_{\text{reg}} \subset V$ denotes the open subscheme of regular elements and that we have fixed a Kostant section $\kappa$ in §3.8.

Proposition 4.8. The action map $G \times B^1 \to V_{\text{reg}}|_{B^1}$, $(g, b) \mapsto g \cdot \kappa_b$ is surjective.

Proof. Part 2 of Proposition 2.11 implies that this map is surjective when restricted to $B^*$, therefore it suffices to prove that if $k/\mathbb{Q}$ is algebraically closed and $b \in D^1(k)$, then every two elements $x, y \in V_{\text{reg}}(k)$ are $G(k)$-conjugate. Let $x = x_s + x_n$ and $y = y_s + y_n$ be the Jordan decompositions of $x$ and $y$. Since the semisimple parts $x_s$ and $y_s$ are $G(k)$-conjugate by Proposition 2.7, we may assume that $x_s = y_s$. The centraliser $L := Z_H(x_s)$ is a reductive group with derived subgroup of type $A_1$ (Lemma 4.3); write $I$ for its Lie algebra. The involution $\theta$ restricts to a stable involution $\theta|_L$ on $L$ (Tho13 Lemma 2.5). Since $x$ and $y$ are regular, $x_n, y_n$ are regular nilpotent elements of $l^{\theta = -1}$. Therefore to prove the lemma, it suffices to prove that $L^\theta \cap G$ acts transitively on the regular nilpotents in $l^{\theta = -1}$. (Note that $L^\theta \subset H^\theta$ but we don’t have $L^\theta \subset G$ in general.)

We first claim that $L^\theta$ acts transitively on the regular nilpotents in $l^{\theta = -1}$. To this end, let $Z(L)$ denote the centre of $L$ and consider the exact sequence

$$0 \to Z(L) \to L \to \text{PGL}_2 \to 0.$$  

(4.2.1)

The involution $\theta$ preserves $Z(L)$ (acting via inversion by [Tho13 Lemma 2.7(3)]) and by Lemma 2.10 we may choose the isomorphism $L/Z(L) \simeq \text{PGL}_2$ so that $\theta$ corresponds to the standard stable involution $\xi = \text{Ad}(\text{diag}(1, -1))$ of $\text{PGL}_2$ from §3.1. An elementary computation in $\mathfrak{sl}_2$ (or Proposition 3.8) shows that $\text{PGL}_2$ acts transitively on the regular nilpotents in $l^{\theta = -1}$. To prove the claim, we only need to show that $L^\theta \to \text{PGL}_2$ is surjective. Since $Z(L)$ is connected (Lemma 1.4.7), $Z(L)/(1 - \theta)Z(L)$ is trivial and therefore taking $\theta$-invariants of (4.2.1) shows that indeed $L^\theta \to \text{PGL}_2$ is surjective, proving the claim.

To prove that $L^\theta \cap G$ acts transitively on the regular nilpotents in $l^{\theta = -1}$, it suffices to prove by the previous paragraph that $L^\theta \cap G$ surjects onto $\text{PGL}_2^\xi$. We first claim that there exists a semisimple element $t \in V$ with centraliser $M = Z_H(t)$ such that $L \subset M$ and such that the derived subgroup of $M$ is of type $A_2$. Indeed, take a Cartan subspace $c \subset V$ containing $x_n$; then $\Phi_c(x_n) = \{\pm \alpha\}$ for some root $\alpha$. Since $\Phi_c$ is not of type $A_1$, there exists a root $\beta$ such that $\{\pm \alpha, \pm \beta, \pm(\alpha + \beta)\} \subset \Phi_c$. Taking $t$ to be an element of $c$ that vanishes exactly on those roots satisfies the requirements.

Again $\theta$ restricts to a stable involution on $M$ and the isomorphism $M/Z(M) \simeq \text{PGL}_3$ can be chosen so that $\theta$ agrees with the standard stable involution $\psi$ of $\text{PGL}_3$ from §3.1. Again $Z(M)$ is connected by Lemma 1.4.7 and taking $\theta$-invariants of the analogue of the sequence (4.2.1) for $M$ gives an exact sequence

$$1 \to Z(M)^\theta \to M^\theta \to \text{PGL}_3^\psi \to 1.$$  

(4.2.2)

A component group calculation (Corollary 3.6) shows that $\text{PGL}_3^\psi$ is connected. Therefore the identity component $(M^\theta)^0$ maps surjectively onto $\text{PGL}_3^\psi$. Since $(M^\theta)^0 \subset M^\theta \cap G$, this implies that $M^\theta = (M^\theta \cap
$G) \cdot Z(M)^\theta$. It follows that $L^\theta = (L^\theta \cap G) \cdot Z(L)^\theta$. Indeed, if $l \in L^\theta$ there exists an element $z \in Z(M)^\theta$ such that $lz \in M^\theta \cap G$. Since $Z(M)^\theta \subset Z(L)^\theta$, we have $lz \in L^\theta \cap G$. We have established the equality $L^\theta = (L^\theta \cap G) \cdot Z(L)$, and it implies that $L^\theta \cap G$ surjects onto $\text{PGL}^2_Z$.

**Remark 4.9.** Proposition [4.8] is false when $H$ is of type $A_1$.

### 4.3 Geometry over $B^1$

Recall from §3.7 that we have introduced a family of projective curves $C \to B$ which is smooth exactly above $B^\text{rs}$.

**Lemma 4.10.** Let $k/\mathbb{Q}$ be a field and $b \in B(k)$. Then $b \in D^1(k)$ if and only if the curve $C_b$ has a unique nodal singularity.

**Proof.** A node is a simple singularity of type $A_1$. Therefore the lemma follows from Lemmas [3.14] and [1.5].

The fibres of the morphism $C \to B$ may be reducible. However, this does not happen over $B^1$:

**Lemma 4.11.** The fibres of $C^1 \to B^1$ are geometrically integral.

**Proof.** The geometric fibres of $C \to B$ are reduced, connected, and over $B^\text{rs}$ these fibres are smooth. Therefore it suffices to prove that $C_b$ is irreducible if $k/\mathbb{Q}$ is algebraically closed and $b \in D^1(k)$. This can be verified by computation in each case, or by the following uniform argument.

Let $Z \subset D^1$ be the locus above which the fibres fail to be geometrically integral. Then $Z$ is closed by [Gro66, Théorème 12.2.1(x)]. We claim that $Z$ is also open. To prove this, it suffices to prove that $Z$ is closed under generalisation [Sta18, Tag 0903]. By [Sta18, Tag 054F] this amounts to showing that for every complete discrete valuation ring $R$ and morphism $\text{Spec } R \to D^1$, the generic point of $\text{Spec } R$ lands in $Z$ if the closed point of $\text{Spec } R$ does. If $b \in D^1(k)$ then $C_b$ has a unique nodal singularity by Lemma [4.10] so either $C_b$ is irreducible with one node or a union of two irreducible components intersecting transversally. Therefore if $b \in D^1(k)$, then $C_b$ is reducible (in other words, $b \in Z$) if and only if the generalised Jacobian $\text{Pic}^0_{C_b/k}$ is an abelian variety [BLR90, §9.2, Example 8]. On the other hand, since the locus of $\text{Spec } R$ where the relative Jacobian $\text{Pic}^0_{C_R/R} \to \text{Spec } R$ (which exists and is a semi-abelian scheme by [BLR90, §9.3, Theorem 7]) is an abelian variety is open (this follows from looking at torsion points), we conclude that the generic fibre of $\text{Pic}^0_{C_R/R}$ is an abelian variety if its special fibre is. It follows that $Z$ is closed under generalisation, proving the claim. Since $D^1$ is irreducible and $Z$ is open and closed, it follows that $Z$ is empty or equal to $D^1$; we will exclude the latter case.

To this end, it suffices to prove that $C_\eta$ is geometrically integral, where $\eta$ is the generic point of $D$. Assume by contradiction that this is not the case. As observed in the previous paragraph, this implies that $\text{Pic}^0_{C_/\eta}$ is an abelian variety. Therefore the finite étale group scheme $J^{rs}[2] \to B^{rs}$ is unramified along $D$. By Zariski–Nagata purity for finite étale covers [Sta18, Tag 0BJE], this implies that $J^{rs}[2]$ extends to a finite étale cover over $B$. Since $B$ is isomorphic to affine space over $k$, this cover must be trivial. However, a monodromy calculation (Propositions [3.22] and [3.23]) shows that $J^{rs}[2]$ is nontrivial. (Recall that we have excluded that $H$ is of type $A_1$.) This is a contradiction, completing the proof of the lemma.

Since $C^1 \to B^1$ has geometrically integral fibres by Lemma [4.11] the group scheme $\text{Pic}^0_{C^1/B^1}$ is well-defined and we denote it by $J^1 \to B^1$ [BLR90, §9.3, Theorem 1]. It is a semi-abelian scheme. The 2-torsion subgroup $J^1[2] \to B^1$ is a quasi-finite étale group scheme; we may therefore view it as a sheaf on the étale site of $B^1$. 28
**Lemma 4.12.** Let \( j : B^\text{rs} \hookrightarrow B^1 \) be the open inclusion. Then \( j_* J^\text{rs}[2] = J^1[2] \) as étale sheaves on \( B^1 \).

**Proof.** Consider the natural morphism \( \phi : J^1[2] \to j_* J^\text{rs}[2] = j_* J^\text{rs}[2] \) obtained by adjunction. Since \( J^1 \to B^1 \) is separated, \( J^1[2] \to B^1 \) is separated as well so \( \phi \) is injective. To prove that \( \phi \) is an isomorphism, it suffices to check this at geometric points of \( B^1 \). Combining the last two sentences, it suffices to prove that \( (J^1[2])_b \) and \( (j_* J^\text{rs}[2])_b \) have the same cardinality for all geometric points \( b \) of \( B^1 \), or even that the cardinality of the latter is bounded above by the cardinality of the first. This is obvious if \( b \) lands in \( B^\text{rs} \), so assume that \( b \) lands in \( D^1 \).

By Lemma 4.11, \( C_b \) is integral and has a unique singularity, which is a node. It follows that \( J^1_b \) has order \( 2^{2g-1} \), where \( g \) is the arithmetic genus of \( C_b \). On the other hand, the order of \( (j_* J^\text{rs}[2])_x \) for \( x \in D^1 \) can only go down under specialisation. It therefore suffices to prove that if \( \eta \) denotes the generic point of \( D \), then \( (j_* J^\text{rs}[2])_\eta \) has order \( 2^{2g-1} \). In fact, we claim that \( \phi_\eta \) is an isomorphism.

To this end, let \( K \) be the fraction field of the discrete valuation ring \( \mathcal{O}_{B, \eta} \) and let \( j_\eta \) be the inclusion \( \text{Spec} K \hookrightarrow \text{Spec} \mathcal{O}_{B, \eta} \). Then the pullback of \( j_* J^\text{rs}[2] \) along \( \text{Spec} \mathcal{O}_{B, \eta} \to B \) equals \( (j_\eta)_* J^K[2] \), where \( J^K_b \) denotes the pullback of \( J^\text{rs} \) along the generic point of \( B \). The curve \( C_{\mathcal{O}_{B, \eta}} \) is regular, since \( \text{Spec} \mathcal{O}_{B, \eta} \to B \) hence \( C_{\mathcal{O}_{B, \eta}} \to C \) is formally smooth and the total space \( C \) is smooth. Therefore a result of Raynaud [BLR90, §9.5, Theorem 1] shows that the identity component of the Picard functor of \( C_{\mathcal{O}_{B, \eta}} \), which equals \( J^1_{\mathcal{O}_{B, \eta}} \) by definition, is isomorphic to the Néron model of \( J_K \). By the Néron mapping property, this shows that \( (j_* J^\text{rs}[2])_\eta = (j_* J^\text{rs}[2])_\eta \). This completes the proof of the claim hence that of the lemma.

4.4 **Summary of properties of \( B^1 \)**

We summarise the properties of \( D^1 \) in the next theorem.

**Theorem 4.13.** Let \( k/\mathbb{Q} \) be an algebraically closed field and \( b \in B(k) \). Then the following are equivalent:

1. \( b \in D^1(k) \);
2. for every semisimple \( v \in V_b(k) \), the derived subgroup of \( Z_H(v) \) is of type \( A_1 \);
3. \( C_b \) is irreducible and has a unique singular point, which is a node.

**Proof.** Combine Lemmas 4.5 and 4.10.

**Theorem 4.14.** The isomorphism \( J^\text{rs}[2] \simeq Z^\text{rs} \) from Proposition 3.21 uniquely extends to an isomorphism \( J^1[2] \simeq Z^1 \) of separated étale group schemes over \( B^1 \).

**Proof.** Since \( J^\text{rs}[2] \) and \( Z^\text{rs} \) are dense in \( J^1[2] \) and \( Z^1 \) respectively, uniqueness is clear. For the existence, denote the open immersion \( B^\text{rs} \hookrightarrow B^1 \) by \( j \). Consider the composition \( \psi : Z^1 \to j_* Z^\text{rs} \twoarrow j_* J^\text{rs}[2] \twoarrow J^1[2] \) of the adjunction morphism \( Z^1 \to j_* Z^\text{rs} \), the pushforward of the isomorphism \( Z^\text{rs} \twoarrow J^\text{rs}[2] \) along \( j \) and the isomorphism \( j_* J^\text{rs}[2] \twoarrow J^1[2] \) of Lemma 4.12. Since \( Z^1 \to B^1 \) is separated, \( \psi \) is injective. It therefore suffices to prove that \( Z^1_b \) and \( J^1_b \) have the same cardinality for every geometric point \( b \) of \( D^1 \). If \( g \) denotes the common arithmetic genus of the fibres of \( C \to B \), then \( Z^1_b \) has cardinality \( 2^{2g-1} \) by Lemma 4.6. On the other hand, \( J^1_b \) also has cardinality \( 2^{2g-1} \) by Lemmas 4.10 and 4.11.

Although it is not necessary for this paper, we expect that an isomorphism similar to the one of Theorem 4.14 holds over the whole of \( B \), but we have not been able to prove it.
5 The compactified Jacobian

We keep the notations from Section 3. Recall from §3.8 that the family of smooth projective curves $C^{rs} \to B^{rs}$ has Jacobian variety $J^{rs} \to B^{rs}$ which is itself a smooth and projective morphism. The goal of this chapter is to extend the $B^{rs}$-scheme $J^{rs}$ to a proper $B$-scheme $\bar{J}$ with good geometric properties. We achieve this using the theory of the compactified Jacobian of Altman–Kleiman [AK80], extended by Esteves [Est01] to incorporate reducible curves. Its construction is given in §5.2 and its basic properties are summarised in Theorem 5.14. Note that the occurrence of reducible fibres is the reason why the definition of $\bar{J}$ is more involved here than in our previous work [Lag20b, §4.3], which treats the $E_6$ case and where only irreducible fibres are present.

The results of this chapter will be useful for the construction of orbits in §6 (specifically §6.2) and the construction of integral representatives in §7.5.

5.1 Generalities on sheaves

The following material is largely taken from [Est01, MRV17]. Let $k$ be an algebraically closed field. By a curve we mean a reduced projective scheme of pure dimension 1 over $k$.

**Definition 5.1.** A coherent sheaf $I$ on a connected curve $X$ is said to be

1. rank-1 if $I_\eta \cong \mathcal{O}_{X,\eta}$ as $\mathcal{O}_{X,\eta}$-modules for every generic point $\eta \in X$;
2. torsion-free if the associated points of $I$ are precisely the generic points of $X$;
3. simple if $\text{End}_k(I) = k$.

We remark that the first two conditions imply the third if $X$ is irreducible and that every torsion-free rank-1 sheaf on a smooth curve is invertible.

A subcurve $Z$ of a curve $X$ is a closed $k$-subscheme that is reduced and of pure dimension 1. If $I$ is a torsion-free sheaf on $X$, its restriction to a subcurve $I|_Z$ is not necessarily torsion-free; it contains a biggest torsion subsheaf and the quotient of $I|_Z$ by this subsheaf is denoted by $I_Z$. The sheaf $I_Z$ is the unique torsion-free quotient of $I$ whose support is equal to $Z$.

**Definition 5.2.** Let $E$ be a vector bundle on a connected curve $X$ of rank $r \geq 1$ and degree $-rd$. Let $I$ be a torsion-free rank-1 sheaf on $X$ with Euler characteristic $\chi(I) = d$. We say that $I$ is $E$-semistable if for every nonempty proper subcurve $Y \subsetneq X$ we have that

$$\chi(I_Y) \geq -\frac{\text{deg}(E|_Y)}{r}.$$  \hspace{1cm} (5.1.1)

We say that $I$ is $E$-stable if for every nonempty proper subcurve the inequality (5.1.1) is strict.

Given a vector bundle $E$ on $X$, we may define its multislope $q^E = \{q^E_C\}$ as follows. It is a tuple of rational numbers, one for each irreducible component $C_i$ of $X$, defined by setting

$$q^E_{C_i} := -\frac{\text{deg}(E|_{C_i})}{\text{rank } E}.$$  

If $Y \subset X$ is a subcurve, write $q^E_Y := \sum_{C_i \subset Y} q^E_{C_i}$, where the sum is taken over those irreducible components $C_i$ that are contained in $Y$. If $E$ is of rank $r$ and degree $-rd$ then $q^E_X = d$. When the vector bundle $E$ is clear from the context we omit the superscript from the notation $q^E$. 

30
Definition 5.3. Let $X$ be a curve and $E$ a vector bundle on $X$ of rank $r$ and degree $-rd$ with multislope $q$. We say that $E$ is general if $q_Y \not\in \mathbb{Z}$ for any nonempty proper subcurve $Y \subseteq X$.

If $I$ is torsion-free rank-1 on $X$, then $I$ is $E$-semistable if and only if $\chi(I_Y) \geq q_Y$ for every nonempty proper subcurve $Y \subset X$, and $E$-stable if every such inequality is strict. Therefore if $E$ is general, a torsion-free rank-1 sheaf on $X$ is $E$-semistable if and only if it is $E$-stable.

The next lemma shows that a family of simple torsion-free rank-1 sheaves has no unexpected endomorphisms. For a quasi-coherent sheaf $\mathcal{F}$ on a scheme $X$, we write $\mathcal{E}nd(\mathcal{F})$ for the sheaf of $\mathcal{O}_X$-module endomorphisms of $\mathcal{F}$, which is again a quasi-coherent sheaf on $X$.

Lemma 5.4. Let $p: \mathcal{X} \to T$ be a flat family of projective curves whose geometric fibres are reduced and connected. Let $I$ be a locally finitely presented $\mathcal{O}_X$-module, flat over $T$, whose geometric fibres above $T$ are simple torsion-free rank-1. Then $p_*\mathcal{E}nd(I) = \mathcal{O}_T$.

Proof. Use [AK80, Corollary (5.3)] and the assumption that each geometric fibre is simple. 

5.2 The definition

Recall from §3.7 that $C \to B$ is a flat projective morphism whose geometric fibres are reduced connected curves, and that this morphism has sections $\infty_1, \ldots, \infty_m: B \to C$ landing in the smooth locus.

Lemma 5.5. For every field $k/\mathbb{Q}$ and $b \in B(k)$, the irreducible components of $C_b$ are geometrically irreducible. Moreover, every such irreducible component contains $\infty_{i,b}$ in its smooth locus for some $i$.

Proof. The first claim follows from the second one. For the second one, we may assume that $k$ is algebraically closed. Consider the line bundle $\mathcal{L} = \mathcal{O}_C(\infty_1 + \cdots + \infty_m)$ on $C$ associated with the divisors $\infty_i$ of $C$. For every $b \in B(k)$, $\mathcal{L}_b$ is ample if and only if every irreducible component of $C_b$ contains $\infty_{i,b}$ for some $i$. Moreover, the locus of elements $b \in B$ for which $\mathcal{L}_b$ is ample is open [Gro66, Corollaire (9.6.4)], $\mathbb{G}_m$-invariant (with respect to the $\mathbb{G}_m$-action on $C \to B$ introduced in §3.7) and contains the central point by Lemma 3.15. These three facts imply that it must be the whole of $B$.

In order to define a compactified Jacobian of $C \to B$, we first construct a vector bundle $E$ on $C$ using properties of the central fibre $C_0$. Recall from Lemma 3.15 that each of the $m$ irreducible components of $C_0$ contains a unique marked point $\infty_{i,0}$. Let $q = \{q_1, \ldots, q_m\}$ be a tuple of rational numbers such that $\sum_{i \in I} q_i = \chi(\mathcal{O}_{C_0}) = 1 - p_a(C_0)$ and $\sum_{i \in I} q_i \notin \mathbb{Z}$ for every nonempty proper subset $I \subset \{1, \ldots, m\}$; it is easy to see that such a tuple exists. Write $q_i = e_i/r$ for some $e_i \in \mathbb{Z}$ and $r \in \mathbb{Z}_{\geq 1}$. By further multiplying $e_i$ and $r$, we may assume that $r \geq m$. Let $E$ be the following vector bundle on $C$:

$$E = \mathcal{O}_C(-e_1 \cdot \infty_1) \oplus \cdots \oplus \mathcal{O}_C(-e_m \cdot \infty_m) \oplus \mathcal{O}_C^r.$$ 

Since the image of $\infty_i: B \to C$ is a divisor of $C$, the line bundles $\mathcal{O}_C(-e_i \cdot \infty_i)$ are well-defined. Note that the vector bundle $E|_{C_0}$ has multislope $q$ by construction. For every geometric point $b$ of $B$, $E|_{C_b}$ is a vector bundle of rank $r$ and degree $-r(1 - p_a(C_0))$ on the curve $C_b$.

Lemma 5.6. For every geometric point $b$ of $B$, the vector bundle $E|_{C_b}$ is general in the sense of Definition 5.3.

Proof. Follows from Lemma 5.5 and the construction of $E$. 

31
We are now ready to define the compactified Jacobian associated with $E$. We assume we have made a choice of $q$ and $E$ as above. Consider the functor
\[ \mathcal{J}_E : \{B\text{-Schemes}\} \to \{\text{Sets}\} \tag{5.2.1} \]
sending a $B$-scheme $T$ to the set of equivalence classes of pairs $(I, \phi)$, where
\begin{itemize}
  \item $I$ is a locally finitely presented $\mathcal{O}_{C_T}$-module, flat over $T$, with the property that for every geometric point $t$ of $T$, $I_t$ is simple torsion-free rank-1, $\chi(I_t) = \chi(\mathcal{O}_{C_t})$ and $I_t$ is $E_t$-stable;
  \item $\phi$ is an isomorphism $\alpha_{t,T}^* I \simeq \mathcal{O}_T$ of $\mathcal{O}_T$-modules.
\end{itemize}
We say two pairs $(I, \phi)$ and $(I', \phi')$ are equivalent if there is an isomorphism $I \simeq I'$ mapping $\phi$ to $\phi'$. We have the following basic representability result [Est01, Theorem B]:

**Proposition 5.7** (Esteves). The functor $\mathcal{J}_E$ is representable by a $B$-scheme $\mathcal{J}_E$.

**Proof.** Let $F$ be the functor from $B$-schemes to sets, sending a $B$-scheme $T$ to the set of equivalence classes of locally finitely presented $\mathcal{O}_{C_T}$-modules $I$, flat over $T$, with the property that for every geometric point $t$ of $T$, $I_t$ is simple torsion-free rank-1, $\chi(I_t) = \chi(\mathcal{O}_{C_t})$ and $I_t$ is $E_t$-stable. (In contrast to $\mathcal{J}_E$, we omit the rigidification $\phi$.) Here we say $I$ and $I'$ are equivalent if there exists an invertible sheaf $\mathcal{L}$ on $T$ such that $I' \simeq \mathcal{L} \otimes I$. Let $F^{\text{et}}$ denote the étale sheafification of $F$. By [Est01, Proposition 34], the functor $F^{\text{et}}$ is representable by an open subspace of the algebraic space parametrising simple torsion-free rank-1 sheaves with no Euler characteristic or stability condition. By Lemma 5.5 and [Est01, Theorem B], the latter algebraic space is in fact a scheme, so $F^{\text{et}}$ is representable by a scheme as well.

On the other hand, the forgetful morphism $\mathcal{J}_E \to F, (T, \phi) \mapsto T$ is an isomorphism of functors, since every $I \in F(T)$ is equivalent to another element $I' \in F(T)$ admitting a rigidification. Since elements of $\mathcal{J}_E$ have no nontrivial automorphisms by Lemma 5.4, étale descent of quasi-coherent sheaves implies that $\mathcal{J}_E$ is an étale sheaf, so we have natural identifications $\mathcal{J}_E = F = F^{\text{et}}$. Since $F^{\text{et}}$ is representable by a scheme by the previous paragraph, the same is true for $\mathcal{J}_E$. \hfill \Box

**Definition 5.8.** We call $\mathcal{J}_E$ a compactified Jacobian of $C \to B$ associated with $E$.

If $C \to B$ has reducible fibres, different choices of $q$ may give rise to different compactified Jacobians. For our purposes, these differences will be harmless and for the remainder of this paper we fix a choice of $q$ and $E$ as above and we simply write $\mathcal{J} = \mathcal{J}_E$.

**Lemma 5.9.** Let $k$ be a field and $b \in B(k)$ such that the curve $C_b$ is integral. Then $\mathcal{J}_b$ parametrises torsion-free rank-1 sheaves on $C_b$ with degree zero, i.e. Euler characteristic $1 - p_a(C_b)$.

**Proof.** If $C_b$ is integral, the $E_b$-stability condition and the simplicity of the sheaves are automatic. \hfill \Box

### 5.3 Basic properties of $\mathcal{J}$

**Lemma 5.10.** The morphism $\mathcal{J} \to B$ is projective\footnote{There are several nonequivalent definitions of a projective morphism but in this case they all agree, see Sta18 Tag 0B45.}.
Proof. Since the vector bundle $E$ is chosen to be general (Lemma 5.6), the notions of $E$-stable and $E$-semistable agree. Therefore, a theorem of Esteves [Est01] Theorem C.1 and C.4] shows that $\bar{J}$ is quasi-projective. Moreover, [Est01] Theorem A.1] shows that $\bar{J} \to B$ is universally closed. We conclude that $\bar{J}$ is projective over $B$. 

Recall from §3.7 that we have defined a $G_m$-action on $C$ such that $C \to B$ is $G_m$-equivariant with respect to the square of the usual $G_m$-action on $B$. By functoriality, this induces a $G_m$-action on $\bar{J}$ too such that $\bar{J} \to B$ is $G_m$-equivariant (again with respect to the square of the usual $G_m$-action on $B$). The following argument will be used in the next two lemmas: if $U \subset \bar{J}$ is an open $G_m$-invariant subset containing the central fibre $J_0$, then $U = \bar{J}$. Indeed, by the properness of $\bar{J} \to B$ the complement of $U$ in $\bar{J}$ projects to a closed $G_m$-invariant subset of $B$ that does not contain the central point $0 \in B$, so must be empty.

**Lemma 5.11.** The variety $\bar{J}$ is smooth.

*Proof.* The family $C \to B$ is a semi-universal deformation of the plane curve singularity $C_0$ (Proposition 3.13). Therefore [MR V17, Fact 4.2(ii)] implies that $\bar{J}$ is smooth in a neighbourhood of $J_0$. Since the smooth locus of $\bar{J}$ is open, $G_m$-invariant and contains $J_0$, it must be the whole of $\bar{J}$. 

We emphasise that the fibres of $\bar{J} \to B$ might be singular above points that do no lie in $B^a$. In fact, we have a precise description of the smooth locus:

**Lemma 5.12.** The morphism $\bar{J} \to B$ is flat of relative dimension $p_a(C_0)$. The smooth locus of $\bar{J} \to B$ coincides with the locus of invertible sheaves.

*Proof.* By [MR V17 Theorem 5.5(ii)], the morphism $\bar{J} \to B$ is flat in a neighbourhood of $J_0$. Since the flat locus is open and $G_m$-invariant, it follows that it must equal the whole of $\bar{J}$. The claim about the smooth locus is [MR V17 Theorem 5.5(iii)].

**Lemma 5.13.** The geometric fibres of $\bar{J} \to B$ are reduced and connected. Consequently, $\bar{J}$ is geometrically integral. Moreover, if $k/\mathbb{Q}$ is an algebraically closed field and $b \in B(k)$ is such that $C_b$ is integral, then $\bar{J}_b$ is integral.

*Proof.* Since all the fibres of $C \to B$ have planar singularities, [MR V17 Theorem A(i)-(iii)] shows that $\bar{J} \to B$ has geometrically reduced and connected fibres. Since $\bar{J}$ is $B$-flat, this implies that $\bar{J}$ is geometrically connected. Since $\bar{J}$ is smooth, it follows that it is geometrically irreducible. To establish the last claim, [MR V17 Corollary 5.14] shows that the number of irreducible components of $\bar{J}_b$ can be calculated in terms of the intersections between the irreducible components of $C_b$. This number is always 1 when $C_b$ is irreducible, as can be seen from [MR V17 Definition 5.12].

For future reference, we summarise the above properties in the following theorem. Write $\bar{J}^1$ for the restriction of $\bar{J}$ to $B^1$. Recall from §4.3 that $J^1 \to B^1$ is the relative generalised Jacobian of the family of integral curves $C^1 \to B^1$. Note that by Lemma 5.9 and the definition of $J^1$ we have an open embedding $J^1 \to \bar{J}^1$. 

**Theorem 5.14.** Let $\bar{J} \to B$ be a compactified Jacobian associated with some choice of $E$ as in Definition 7.8. Then the morphism $\bar{J} \to B$ is flat, projective and restricts to $J^a$ over $B^a$. Its geometric fibres are reduced and connected. The scheme $\bar{J}$ is geometrically integral and smooth over $\mathbb{Q}$. The smooth locus of $J^1 \to B^1$ is isomorphic to $J^1 \to B^1$. The complement of $J^1$ in $\bar{J}$ has codimension $\geq 2$. 

33
Proof. Only the last two sentences remain to be established. The claim about the smooth locus of $\bar{J}^1$ follows from Lemmas 5.9 and 5.12 and the definition of $\bar{J}^1$. For the claim about the codimension, let $Z$ be the complement of $J^1$ in $J$. Then $Z$ is supported above the discriminant locus $D$ of $B$. Moreover the fibres of the map $\bar{J}_{D^1} \to D^1$ are geometrically integral by Lemmas 5.11 and 5.13 so the fibres of the map $Z_{\mid D^1} \to D^1$ have dimension strictly less than those of $\bar{J}_{\mid D^1} \to D^1$. Combining the last two sentences proves the claim. 

\[ \Box \]

5.4 The Białynicki-Birula decomposition of $\bar{J}$

We recall the Białynicki-Birula decomposition [BB73] from geometric representation theory. If $k$ is a field and $X$ is a scheme of finite type over $k$, we define a decomposition of $X$ to be a collection of locally closed subschemes $X_1, \ldots, X_n$ of $X$ such that the underlying topological space of $X$ is a disjoint union of the underlying topological spaces of the $X_i$. If in addition $X$ is separated over $k$ and endowed with a $\mathbb{G}_m$-action and if $x \in X$ we say that $\lim_{\lambda \to 0} \lambda \cdot x$ exists if the action map $\mathbb{G}_m \to X, \lambda \mapsto \lambda \cdot x$ extends (necessarily uniquely) to a morphism $\mathbb{A}^1_k \to X$.

Proposition 5.15. Suppose that $X$ is a smooth and separated scheme of finite type over a field $k$, endowed with a $\mathbb{G}_m$-action. Then the closed subscheme of fixed points $X^{\mathbb{G}_m}$ is smooth; let $F_1, \ldots, F_n$ denote its connected components. Suppose in addition that $\lim_{\lambda \to 0} \lambda \cdot x$ exists for every $x \in X$. Then there exists a decomposition of $X$ into locally closed subschemes $X_i$ and morphisms $X_i \to F_i$ which are affine space fibrations in the Zariski topology.

Proof. See [JS19] Theorem 1.5 for a modern proof, which treats the generality in which we have stated it. We may informally describe $X_i$ as those points $x \in X$ whose limit $\lim_{\lambda \to 0} \lambda \cdot x$ lies in $F_i$, and the map $X_i \to F_i$ as taking the limit $x \mapsto \lim_{\lambda \to 0} \lambda \cdot x$. 

\[ \Box \]

Corollary 5.16. In the setting of Proposition 5.15, assume furthermore that $X$ is geometrically integral and $X^{\mathbb{G}_m}$ is finite. Then there exists an open subset of $X$ isomorphic to affine space $\mathbb{A}^{\dim X}_k$.

Proof. Let $F_1, \ldots, F_n$ denote the connected components of $X^{\mathbb{G}_m}$; since $X^{\mathbb{G}_m}$ is smooth and finite each $F_i$ is the spectrum of a separable field extension $k_i$ of finite degree over $k$. Let $X_1, \ldots, X_n$ be the decomposition of $X$ of Proposition 5.15. Then each $X_i$ is isomorphic to $\mathbb{A}^{k_i}_k$ for some integer $n_i \geq 0$. There exists an $X_1$ say $X_1 = X$, which is of maximal dimension $\dim X$. Since $X_1$ is locally closed, it is an open subset of its closure $\bar{X}_1 = X$, so $X_1$ is an open subset of $X$. Since $X$ is geometrically irreducible, the same is true for $X_1$. This implies that $X_1 \times_k k_1$ is irreducible, so $k_1 = k$. Therefore $X_1$ is isomorphic to $\mathbb{A}^{\dim X}_k$.

\[ \Box \]

Remark 5.17. The proof shows that under the assumptions of Corollary 5.16 $X$ is even decomposed into affine cells.

We will apply Corollary 5.16 to the compactified Jacobian $\bar{J} \to B$ constructed in §5.2. Recall from §5.3 that $\bar{J}$ inherits a $\mathbb{G}_m$-action from $C$. We denote the central fibre of $\bar{J}$ by $\bar{J}_0$.

Lemma 5.18. The set of $\mathbb{G}_m$-fixed points $\bar{J}_0^{\mathbb{G}_m}$ is finite.

Proof. This follows from calculations of Beauville [Bea90] §4.1 if $C_0$ is integral. It seems likely that one can extend his analysis to reducible curves, but we will proceed differently. We will assume that all schemes are base changed to a fixed algebraic closure $k$ of $\mathbb{Q}$. Let $J(C_0)$ be the generalised Jacobian of $C_0$ parametrising line bundles having multidegree zero, i.e. degree zero on each irreducible component of $C_0$. Then $J(C_0)$ is an algebraic group acting on $\bar{J}_0$, compatibly with the $\mathbb{G}_m$-actions on $J(C_0)$ and $\bar{J}_0$. 

34
First we claim that the closure of every $G_m$-orbit of a point in $J(C_0)$ contains the identity. Indeed, every point of $[L] \in J(C_0)(k)$ is represented by a Cartier divisor $D_1 = \deg(D_1)\infty_{1,0} + \cdots + D_m = \deg(D_m)\infty_{m,0}$, where $D_i$ is a Cartier divisor supported on the smooth affine part of the irreducible component $C_{0,i}$ of $C_0$ containing $\infty_{i,0}$. Since every smooth point $P$ of $C_{0,i}$ satisfies $\lim_{\lambda \to \infty} \lambda \cdot P = \infty_{i,0}$ (as can be seen from the definition of the $G_m$-action on $C_0$ in [37] and Table 1], we see that $\lambda \cdot [L] \to 0$ as $\lambda \to \infty$, proving the claim.

Secondly, we claim that the action of $J(C_0)$ on $\tilde{J}_0$ has finitely many orbits. Indeed, let $p \in C_0$ be the unique singular point. Since $p$ is an ADE-singularity, there are only finitely many isomorphism classes of torsion-free rank-1 modules over the completed local ring $\mathcal{O}_{C_0,p}$ (see [Knö87], in fact this property can be used to characterise ADE-singularities amongst Gorenstein singularities). It therefore suffices to prove that if $[\mathcal{F}] = [\mathcal{G}] \in J_0(k)$ are two sheaves whose completed stalks at $p$ are isomorphic, then $\mathcal{F} \simeq \mathcal{G} \oplus \mathcal{L}$, where $\mathcal{L}$ is a line bundle on $C_0$ whose multidegree can only take finitely many values (independently of $\mathcal{F}$ and $\mathcal{G}$). To prove this, consider the Hom-sheaf $\mathcal{H} = \text{Hom}(\mathcal{F}, \mathcal{G})$ and the endomorphism sheaf $\mathcal{E} = \text{End}(\mathcal{F})$. Since $\mathcal{F}|_{C_0\setminus \{p\}}$ is a line bundle, $\mathcal{E}$ is a coherent commutative $\mathcal{O}_{C_0}$-algebra which is generically isomorphic to $\mathcal{O}_{C_0}$, and $\mathcal{H}$ is a coherent $\mathcal{E}$-module. Since the formation of $\mathcal{E}$ and $\mathcal{E}$ commutes with flat base change [Sta18 Tag 0C8I], the completed stalk $\mathcal{H}_p \otimes \mathcal{O}_{C_0,p}$ is free of rank 1 over $\mathcal{E}_p \otimes \mathcal{O}_{C_0,p}$. It follows that $\mathcal{H}_p$ is free of rank 1 over $\mathcal{E}_p$, so the stalks $\mathcal{F}_p, \mathcal{G}_p$ are isomorphic $\mathcal{O}_{C_0,p}$-modules. (An isomorphism is given by choosing an $\mathcal{E}_p$-generator of $\mathcal{H}_p$.) By spreading out such an isomorphism, we may find an open subset $U \subset C_0$ containing $p$ and an isomorphism $\phi_U : \mathcal{F}|_V \simeq \mathcal{G}|_V$. The restrictions of $\mathcal{F}, \mathcal{G}$ to $C_0 \setminus \{p\}$ are line bundles. Since $C_0$ is connected and $p$ is its unique singular point, the complement $C_0 \setminus U$ is a union of finitely many points. We may therefore find an open subset $V \subset C_0 \setminus \{p\}$ containing those points and an isomorphism $\phi_V : \mathcal{F}|_V \simeq \mathcal{G}|_V$. The transition map $(\phi_V)^{-1}|_{U \cap V} \circ (\phi_U)|_{U \cap V} : \mathcal{F}|_{U \cap V} \simeq \mathcal{G}|_{U \cap V}$ defines an element $f \in \text{H}^0(U \cap V, \mathcal{O}_{C_0} \otimes \mathcal{L}|_{U \cap V})$. Let $\mathcal{L}$ be the line bundle on $C_0$ obtained by glueing $\mathcal{O}_U$ and $\mathcal{O}_V$ along the automorphism $f$. One can then explicitly check that the maps

\[ \mathcal{F}_U \otimes \mathcal{O}_U \to \mathcal{G}_U : s \otimes 1 \mapsto \phi_U(s), \]
\[ \mathcal{F}_V \otimes \mathcal{O}_V \to \mathcal{G}_V : s \otimes 1 \mapsto \phi_V(s), \]

glue to an isomorphism $\mathcal{F} \otimes \mathcal{L} \simeq \mathcal{G}$. The multidegree of $\mathcal{L}$ can only take on finitely many values (when we vary $\mathcal{F}$ and $\mathcal{G}$ in $J_0$) because of the $E$-stability condition imposed on sheaves in $J_0$. This completes the proof of the claim. (We thank Jesse Leo Kass for his help with the proof of this claim.)

We now use the last two paragraphs to show that $\mathcal{J}_0^{G_m}$ is finite. Indeed, by the second claim, it suffices to prove that every $J(C_0)$-orbit contains at most one $G_m$-fixed point. If $x \in \mathcal{J}_0^{G_m}$ and $g \in J(C_0)$ are such that $g \cdot x \in \mathcal{J}_0^{G_m}$, then $g^{-1}(\lambda \cdot g)$ lies in the stabiliser of $x$ in $J(C_0)$ for all $\lambda \in G_m$. Since this stabiliser is closed, the first claim implies that it contains $\text{lim}_{\lambda \to \infty} g^{-1}\lambda \cdot g = g^{-1}$. Therefore $g$ lies in the stabiliser of $x$, that is $g \cdot x = x$. We conclude that $x$ is the only $G_m$-fixed point in the $J(C_0)$-orbit of $x$. \hfill \square

**Theorem 5.19.** The variety $\mathcal{J}$ has a dense open subset isomorphic to affine space $\mathbb{A}_d^d$ for some $d \geq 1$.

**Proof.** The compactified Jacobian is a smooth, geometrically integral and quasi-projective scheme over $\mathbb{Q}$ (Theorem 5.13). Since $J \to B$ is proper and $\text{lim}_{\lambda \to 0} \lambda \cdot b$ exists for every $b \in B$, $\text{lim}_{\lambda \to 0} \lambda \cdot x$ exists for every $x \in J$. We wish to apply Corollary 5.10 so it suffices to prove that the fixed point locus $\mathcal{J}_0^{G_m}$ is finite. Since $\mathcal{J}_0^{G_m}$ consists of the central point 0, it suffices to prove that $\mathcal{J}_0^{G_m}$ is finite, which is exactly Lemma 5.18. \hfill \square

**Remark 5.20.** The Białyńcki-Birula decomposition gives a canonical decomposition of $\mathcal{J}$ into locally closed subschemes isomorphic to affine space. If $H$ is of type $A_g$, $C \to B$ is the family of odd hyperelliptic curves of genus $g$ (see Table [7] and this decomposition is closely related to the Mumford representation of a point in the Jacobian of such a curve [Mum77, IIIa]. It would be interesting to obtain a similarly concrete interpretation of this decomposition for other families of curves studied here.
6 Constructing orbits

We keep the notations from Section 3. The goal of this chapter is to construct for every \( b \in B^* \mathbb{Q} \) and every element of \( \text{Sel}_2 J_b \times \mathbb{Q} \)-orbit of \( V_b \), see Corollary 6.3. The technical input is the Zariski triviality of a certain universal torsor on \( J^* \) in [6.2] see Theorem 6.4. This will be achieved using generalities concerning torsors on open subsets of affine spaces developed in [6.1].

6.1 Torsors on open subsets of affine space

The purpose of this subsection is to prove the following theorem, which will be useful in the proof of Theorem 6.4.

**Theorem 6.1.** Let \( k \) be a field of characteristic zero and \( X \) an open subset of \( \mathbb{A}^n_k \) whose complement has codimension \( \geq 2 \). Let \( G \) be a reductive group over \( k \) and let \( T \to X \) be a \( G \)-torsor. Suppose that \( X \) contains a \( k \)-rational point over which \( T \) is trivial. Then \( T \) is Zariski locally trivial.

**Example 6.2.** We illustrate Theorem 6.1 in the concrete case \( G = \text{PGL}_2 \). If \( k \) and \( X \) are as in the theorem, then a \( \text{PGL}_2 \)-torsor can alternatively be viewed as a Severi–Brauer curve \( C \to X \). In other words, \( C \to X \) is a smooth projective family of genus zero curves (i.e. conics). Suppose that \( X \) contains a point \( x \in X(k) \) such that the conic \( C_x \) has a \( k \)-rational point. Then Theorem 6.1 says that \( C \) is a projective bundle over \( X \). This implies that all the other fibres of \( C \to X \) also contain a \( k \)-rational point.

Theorem 6.1 might be unsurprising to experts, although we have not been able to locate it explicitly in the literature. It follows from a slight variant of the formalism developed in [CT80] using pointed sets rather than abelian groups. We take a different route and give a short proof which was suggested to us by Colliot-Thélène. We thank him for letting us to include the argument here.

The crucial input is the following result of Raghunathan–Ramanathan, see [RRS84] Theorem 1.1 and the remark immediately thereafter.

**Proposition 6.3.** Let \( k \) be a perfect field and \( G \) a reductive group over \( k \). Then every \( G \)-torsor on \( \mathbb{A}^1_k \) is isomorphic to the pullback of a \( G \)-torsor on \( \text{Spec} k \) along the map \( \mathbb{A}^1_k \to \text{Spec} k \).

**Proof of Theorem 6.1.** Let \( p: \mathbb{A}^n_k \to \mathbb{A}^{n-1}_k \) be the projection onto the first \( n - 1 \) coordinates and let \( p_X: X \to \mathbb{A}^{n-1}_k \) be its restriction to \( X \). If \( K \) denotes the function field of \( \mathbb{A}^{n-1}_k \), then the assumptions on \( X \) imply that the generic fibre of \( p_X \) is isomorphic to \( \mathbb{A}^1_K \). By Proposition 6.3 the restriction of \( T \) to this generic fibre is induced from a torsor \( T_0 \) on \( \text{Spec} K \) along the map \( \mathbb{A}^1_K \to \text{Spec} K \).

Since \( k \) is infinite, we may choose a section \( s: \mathbb{A}^{n-1}_k \to \mathbb{A}^n_k \) of \( p \) such that its image does not contain any generic point of the complement of \( X \) in \( \mathbb{A}^n_k \). Let \( X_1 = s^{-1} (X \cap s(\mathbb{A}^{n-1}_k)) \) and let \( T_1 \) be the pullback of \( T \) along \( s|_{X_1}: X_1 \to X \). By our choice of \( s \), \( X_1 \) is an open subset of \( \mathbb{A}^n_k \) whose complement has codimension \( \geq 2 \). The generic fibre of \( T_1 \) is a torsor on \( \text{Spec} K \) isomorphic to \( T_0 \).

Replacing \( T \) by \( T_1 \) and iterating this process, we obtain a torsor \( T_n \) on \( \text{Spec} k \) whose pullback along \( X \to \text{Spec} k \) is generically isomorphic to \( T \). By known cases of the Grothendieck–Serre conjecture (Corollary 2.17), \( T \) and \( T_n \times_k X \) are Zariski locally isomorphic. Since \( X \) has a \( k \)-point above which \( T \) is trivial, the same is true for \( T_n \times_k X \) hence \( T_n \) is trivial itself. We conclude that \( T \) is Zariski locally trivial, as desired.

\[ \square \]
6.2 A universal torsor

Recall from §3.8 that \( J^{rs} \to B^{rs} \) denotes the relative Jacobian of the family of smooth curves \( C^{rs} \to B^{rs} \), that \( Z \to B \) denotes the universal stabilizer of the Kostant section \( \kappa \), and that there is an isomorphism of finite étale group schemes \( J^{rs}[2] \cong Z^{rs} \) over \( B^{rs} \).

Since \( J^{rs} \to B^{rs} \) is an abelian scheme, the multiplication-by-2 map \( J^{rs} \to J^{rs}[2] \) is a \( J^{rs}[2] \)-torsor. Pushing out this torsor along the maps \( J^{rs}[2] \to Z^{rs} \to G \) defines a \( G \)-torsor \( T^{rs} \to J^{rs} \). (This procedure is also called ‘changing the structure group’.) The following theorem is one of the main technical results of this paper, and is the essential input for constructing orbits associated with elements of \( J_b(\mathbb{Q}) \) (Theorem 5.6).

**Theorem 6.4.** The torsor \( T^{rs} \) is Zariski locally trivial. That is, for every \( x \in J^{rs} \) there exists an open subset \( U \subset J^{rs} \) containing \( x \) such that \( T^{rs}|_U \) is trivial.

To briefly explain why this is relevant for constructing orbits, note that if \( b \in B^{rs}(\mathbb{Q}) \) and \( P \in J_b(\mathbb{Q}) \), the image of \( P \) under the composition \( J_b(\mathbb{Q})/2J_b(\mathbb{Q}) \to H^1(\mathbb{Q}, J_b[2]) \to H^1(\mathbb{Q}, G) \) coincides with the isomorphism class of the pullback of \( T^{rs} \) along \( P \) : \( \text{Spec} \mathbb{Q} \to J^{rs} \). Theorem 6.4 implies that this pullback defines the trivial class in \( H^1(\mathbb{Q}, G) \), which implies that it corresponds to a \( G(\mathbb{Q}) \)-orbit of \( V_b(\mathbb{Q}) \); see Theorem 6.6 for full details.

**Proof of Theorem 6.4.** Recall from §3 that \( B^1 \subset B \) is an open subset containing \( B^{rs} \) and that the family of curves \( J^1 \to B^1 \) is the relative (generalised) Jacobian of the family of curves \( C^1 \to B^1 \). By Theorem 4.1.14 the isomorphism \( J^{rs}[2] \cong Z^{rs} \) extends to an isomorphism \( J^1[2] \cong Z^1 \) of quasi-finite étale group schemes over \( B^1 \). The multiplication-by-two map \( J^1 \to J^1[2] \) is a \( J^1[2] \)-torsor, and pushing out this torsor along the composition \( J^1[2] \to Z^1 \to G \) defines a \( G \)-torsor \( T^1 \to J^1 \). By construction, the restriction of \( T^1 \) to \( J^{rs} \) is isomorphic to \( T^{rs} \).

To prove the theorem, it suffices to prove that \( T^1 \) is Zariski locally trivial. Using known cases of the Grothendieck–Serre conjecture (Corollary 2.17) it even suffices to prove that \( T^1 \) is Zariski locally trivial when restricted to a nonempty open subset of \( J^1 \).

Recall from §3 that we have constructed a scheme \( \overline{J} \to B \) containing \( J^1 \) as an open subscheme. By Theorem 5.14 the complement of \( J^1 \) in \( \overline{J} \) has codimension \( \geq 2 \); by Theorem 5.19 \( \overline{J} \) contains an open dense subscheme \( U \) isomorphic to affine \( \mathbb{Q} \)-space. This implies that the complement of \( U^1 := U \cap J^1 \) in \( U \) has codimension \( \geq 2 \).

We claim that \( T^1|_{U^1} \) is Zariski locally trivial. By Theorem 6.1 it suffices to prove that \( T^1_x \) is trivial for some \( x \in U^1(\mathbb{Q}) \). In fact, we will show the stronger statement that \( \{ x \in J^1(\mathbb{Q}) \mid T^1_x \text{ is trivial} \} \) is Zariski dense in \( J^1 \). Indeed, since \( J^1 \) is a rational variety (it contains \( U^1 \) as a dense open subscheme), the set \( J^1(\mathbb{Q}) \) is dense in \( J^1 \). Since the multiplication-by-two map \( J^1 \to J^1[2] \) is dominant, the subset \( 2J^1(\mathbb{Q}) \subset J^1(\mathbb{Q}) \) is still dense in \( J^1 \). By construction of \( T^1 \), the pullback of \( T^1 \) along a point \( x \in 2J^1(\mathbb{Q}) \) is trivial. This completes the proof of the claim, hence the proof of the theorem.

6.3 Constructing orbits for 2-descent elements

We start by applying a well known lemma from arithmetic invariant theory recalled in §2.4 to give a cohomological description of the \( G \)-orbits of \( V \). For every \( \mathbb{Q} \)-algebra \( R \) and \( b \in B^{rs}(R) \) we write \( J_b := J_b^{rs} \) for the Jacobian of \( C_b \).
Corollary 6.5. Let $R$ be a $\mathbb{Q}$-algebra and $b \in B^{rs}(R)$. Then the association $v \mapsto \{g \in G \mid g \cdot v = \kappa_b\}$ induces an injection

$$\gamma_b : G(R) \setminus V_b(R) \hookrightarrow H^1(R, J_b[2]).$$

Its image coincides with the pointed kernel of the map $H^1(R, J_b[2]) \xrightarrow{\sim} H^1(R, Z_b) \rightarrow H^1(R, G)$.

Proof. We apply Lemma 2.13 to the action of $G_{B^{rs}}$ on $V^{rs}$. Indeed, the action map $G \times B^{rs} \rightarrow V^{rs}, (g, b) \mapsto g \cdot \kappa_b$ is étale (Proposition 3.11) and it is surjective by Proposition 2.11. Pulling back along $b : \text{Spec} \, R \rightarrow B^{rs}$ and using the isomorphism $J_b[2] \simeq Z_b$ from Proposition 3.21 gives the desired bijection. 

We now piece all the ingredients obtained so far together to deduce our first main theorem.

Theorem 6.6. Let $R$ be a local $\mathbb{Q}$-algebra (for example, a field of characteristic zero) and $b \in B^{rs}(R)$. Then the image of the 2-descent map $J_b(R)/2J_b(R) \rightarrow H^1(R, J_b[2])$ lies in the image of $\gamma_b$ of Corollary 6.5. Consequently, there is a canonical injection

$$\eta_b : J_b(R)/2J_b(R) \hookrightarrow G(R) \setminus V_b(R)$$

compatible with base change.

Proof. By Corollary 6.5 it suffices to prove that the composition $J_b(R)/2J_b(R) \rightarrow H^1(R, J_b[2]) \simeq H^1(R, Z_b) \rightarrow H^1(R, G)$ is trivial. Recall that in 6.2 we have constructed a $G$-torsor $T^{rs} \rightarrow J^{rs}$ such that its pullback along a point $P : \text{Spec} \, R \rightarrow J^{rs}$ defines a $G$-torsor $T^{rs}_P \rightarrow \text{Spec} \, R$ whose isomorphism class equals the image of $P$ under the above composite map. Since $T^{rs}$ is Zariski locally trivial by Theorem 6.4, $T^{rs}_P$ is Zariski locally trivial. Since $R$ is a local ring, it follows that $T^{rs}_P$ is trivial. This completes the proof. 

Remark 6.7. In the proof of Theorem 6.4 we have shown the stronger statement that the torsor $T^1 \rightarrow J^1$ (a natural extension of $T^{rs}$ to $J^1$) is Zariski locally trivial. A straightforward adaption of the proof of Theorem 6.4 then shows that if $R$ is a local ring and $b \in B^1(R)$ (instead of $b \in B^{rs}(R)$), then there exists an injection $J_b^1(R)/2J_b^1(R) \hookrightarrow G(R) \setminus V_b^{\text{reg}}(R)$. We do not know if this observation is useful.

6.4 Constructing orbits for 2-Selmer elements

The next proposition might be well known to experts — see for example [PR94] Remark after Theorem 6.22 — but we believe it deserves to be stated explicitly. We slightly deviate from our standing notation and allow $G$ to be an arbitrary split semisimple group in this proposition.

Proposition 6.8. Let $G$ be a split semisimple group over a number field $k$. Then the kernel of $H^1(k, G) \rightarrow \prod_v H^1(k_v, G)$ (where $v$ runs over all places) is trivial.

We emphasise that $H^1(k, G) \rightarrow \prod_v H^1(k_v, G)$ is merely a map of pointed sets, and that it need not be injective. (Take $G$ to be a special orthogonal group.)

Proof. We have an exact sequence

$$1 \rightarrow \mu \rightarrow G_{\text{sc}} \rightarrow G \rightarrow 1$$

where $G_{\text{sc}}$ is simply connected and $\mu$ is a finite subgroup of a split torus (i.e. a product of $\mu_n$’s). This sequence induces a long exact sequence in nonabelian cohomology. Let $\alpha \in H^1(k, G)$ be a class with $\alpha_v = 1$ for all places $v$ of $k$. Since $H^2(k, \mu) \rightarrow \prod_v H^2(k_v, \mu)$ is injective by the Hasse principle for the Brauer group, we see that $\alpha$ lifts to a class $\beta \in H^1(k, G_{\text{sc}})$. Since $\mu$ is a central subgroup of $G_{\text{sc}}$, any other lift of $\alpha$ is
given by $\lambda \beta$, where $\lambda \in H^1(k, \mu)$ is a cocycle. We will show that we can choose $\lambda$ so that $\lambda \beta$ is trivial. By the Hasse principle for simply connected groups [PR94 Theorem 6.6], the map $H^1(k, G_{sc}) \to \prod_v H^1(k_v, G_{sc})$ is injective. (This map is even bijective.) If $v$ is a finite or complex place, then $H^1(k_v, G_{sc})$ is trivial [Poo17 Theorem 5.12.24(b)]. If $v$ is real then $\beta_v \in H^1(k_v, G_{sc})$ has trivial image in $H^1(k_v, G)$ so comes from an element of $H^1(k_v, \mu)$. Since $H^1(k, \mu) \to \prod_v \text{real}_v H^1(k_v, \mu)$ is surjective (this follows from the case $\mu = \mu_n$), we may choose $\lambda \in H^1(k, \mu)$ such that $\lambda_v \beta_v = 1$ for every real place $v$. This implies that $\lambda \beta$ is trivial, as required.

**Corollary 6.9.** Let $k$ be a number field and $b \in B^n(k)$. Let $\text{Sel}_2 J_b$ be the 2-Selmer group of the abelian variety $J_b/k$. Then $\text{Sel}_2 J_b \subset H^1(k, J_b[2])$ is contained in the image of $\gamma_b$. Consequently, the injection $\eta_b$ from Theorem 6.7 extends to an injection

$$\text{Sel}_2 J_b \hookrightarrow G(k) \setminus V_b(k).$$

**Proof.** We have a commutative diagram for every place $v$:

$$\begin{array}{ccc}
J_b(k)/2J_b(k) & \xrightarrow{\delta} & H^1(k, J_b[2]) \\
\downarrow & & \downarrow \\
J_b(k_v)/2J_b(k_v) & \xrightarrow{\delta_v} & H^1(k_v, J_b[2])
\end{array}$$

By Corollary 6.4 it suffices to prove that 2-Selmer elements in $H^1(k, J_b[2])$ are killed under the composition $H^1(k, J_b[2]) \xrightarrow{\delta} H^1(k, Z_G(\kappa_b)) \xrightarrow{\gamma_b} H^1(k, G)$. By definition, an element of $\text{Sel}_2 J_b$ consists of a class in $H^1(k, J_b[2])$ whose restriction to $H^1(k_v, J_b[2])$ lies in the image of $\delta_v$ for every place $v$. So by Theorem 6.6 the image of such an element in $H^1(k_v, G)$ is trivial for every $v$. Proposition 6.8 completes the proof.

### 6.5 Reducible orbits and marked points

Recall from Definition 3.12 that an element of $V^{re}(k)$ is $k$-reducible if it is $G(k)$-conjugate to a Kostant section. Recall from 3.7 that $\infty_1, \ldots, \infty_m$ denote the set of marked points of $C \to B$.

**Proposition 6.10.** Let $k/\mathbb{Q}$ be a field and $b \in B^n(k)$. Then the image under $\eta_b$: $J_b(k)/2J_b(k) \hookrightarrow G(k) \setminus V_b(k)$ of the subgroup of $J_b(k)/2J_b(k)$ generated by $\{\infty_1 - \infty_1, \ldots, \infty_m - \infty_1\}$ coincides with the set of $k$-reducible $G(k)$-orbits of $V_b(k)$. Moreover, the set of $k$-reducible $G(k)$-orbits has the maximal size $2^{m-1}$ if and only if the inclusion $Z_G(\kappa_b) \subset Z_{H^1(\kappa_b)}$ is surjective on $k$-points.

**Proof.** The proof is very similar to [RT18 Lemma 2.11]. For a scheme $X/k$ we write $H_1(X, \mathbb{F}_2) := \text{Hom}(H^1_{et}(X_k, \mathbb{F}_2), \mathbb{F}_2)$, where $H^1_{et}$ denotes étale cohomology. We have an exact sequence of étale homology groups

$$1 \to \mu_2^m / \Delta(\mu_2) \to H_1(C_b^0, \mathbb{F}_2) \to H_1(C_b, \mathbb{F}_2) \to 1. \quad (6.5.1)$$

Let $H_{sc} \to H$ be the simply connected cover of $H$ and let $C_{H_{sc}}$ be the centre of $H_{sc}$. By [Tho13 Theorem 4.10], the sequence (6.5.1) is isomorphic to

$$1 \to C_{H_{sc}}[2] \to Z_{H_{sc}}(\kappa_b) \to Z_G(\kappa_b) \to 1. \quad (6.5.2)$$

It follows that the duals of these sequences are also isomorphic. We will calculate these duals and their connecting maps in Galois cohomology.
The dual of (6.5.1) is isomorphic to
\[ 1 \to J_b[2] \to H^1_{et}(C_{b,k^*}, F_2) \to (\mu_2^m)_{\Sigma=0} \to 1. \] (6.5.3)
Here we use the identification \( J_b[2] = H^1_{et}(C_{b,k^*}, F_2) \), and \((\mu_2^m)_{\Sigma=0}\) denotes the subset of \( \mu_2^m \) of elements summing to zero. An explicit calculation shows that the image of the connecting map \((\mu_2^m)_{\Sigma=0}(k) \to H^1(k, J_b[2])\) coincides with the image of the subgroup of \( J_b(k)/2J_b(k) \) generated by \( \{ \infty_2 - \infty_1, \ldots, \infty_m - \infty_1 \} \) under the 2-descent map \( J_b(k)/2J_b(k) \leftrightarrow H^1(k, J_b[2]). \)

On the other hand, we claim that the dual of (6.5.2) is isomorphic to
\[ 1 \to Z_G(\kappa_b) \to Z_{H^\theta}(\kappa_b) \to \pi_0(H^\theta) \to 1. \] (6.5.4)
Indeed, the identification of the first two terms follows from [Tho13, Corollary 2.9] and the existence of a nondegenerate pairing on \( Z_G(\kappa_b) \) [Tho13, Corollary 2.12]. It follows from Lemma 2.13 that we may identify the last term with \( \pi_0(H^\theta) \). Next, we claim that the image of the connecting map \( \pi_0(H^\theta) \to H^1(k, Z_G(\kappa_b)) \) coincides with the image of the \( k \)-reducible orbits in \( V_b(k) \) under the map \( G(k)/V_b(k) \to H^1(k, Z_G(\kappa_b)) \) from Lemma 2.13 Indeed, consider the commutative diagram

\[
\begin{array}{ccc}
G(k)/V_b(k) & \longrightarrow & H^\theta(k)/V_b(k) \\
\downarrow & & \downarrow \\
H^1(k, Z_G(\kappa_b)) & \longrightarrow & H^1(k, Z_{H^\theta}(\kappa_b))
\end{array}
\]

where the horizontal maps are induced by the inclusions \( G \subset H^\theta \) and \( Z_G(\kappa_b) \subset Z_{H^\theta}(\kappa_b) \), and the vertical maps arise from Lemma 2.13. It follows from Corollary 3.3 that the map \( H^1(k, G) \to H^1(k, H^\theta) \) has trivial pointed kernel. Moreover all \( k \)-reducible elements in \( V_b(k) \) are \( H^\theta(k) \)-conjugate by Proposition 5.8. Therefore the set of \( k \)-reducible \( G(k) \)-orbits corresponds to the kernel of \( H^1(k, Z_G(\kappa_b)) \to H^1(k, Z_{H^\theta}(\kappa_b)) \) which, using (6.5.4), coincides with the image of the map \( \pi_0(H^\theta) \to H^1(k, Z_G(\kappa_b)) \). This proves the claim and the first part of the proposition.

To prove the remaining part, note that there are \( 2^{m-1} \) \( k \)-reducible orbits if and only if the map \((\mu_2^m)_{\Sigma=0}(k) \to H^1(k, J_b[2])\) is injective. By considering the long exact sequences associated with the isomorphic sequences (6.5.3) and (6.5.4), this is equivalent to the surjectivity of \( H^0(k, Z_G(\kappa_b)) \to H^0(k, Z_{H^\theta}(\kappa_b)) \).

7 Integral representatives

We keep the notations from Section 3. In this chapter we introduce integral structures for \( G \) and \( V \) and prove that for large primes \( p \), the image of the map from Theorem 6.6 applied to \( R = \mathbb{Q}_p \) lands in the orbits which admit a representative in \( \mathbb{Z}_p \). See Theorem 7.6 for a precise statement. In §7.6 we deduce an integrality result for orbits over \( \mathbb{Q} \) (as opposed to orbits over \( \mathbb{Q}_p \)).

7.1 Integral structures

So far we have considered properties of the pair \( (G, V) \) over \( \mathbb{Q} \). In this subsection we define these objects over \( \mathbb{Z} \).

Indeed, the pinning of \( H \) chosen in §3.1 extends to a Chevalley basis of \( \mathfrak{h} \) (in the sense of [Bor70, §1.2]), hence a \( \mathbb{Z} \)-form \( \mathfrak{h} \). This determines a \( \mathbb{Z} \)-form \( \mathfrak{g} \cap \mathfrak{h} \) of \( \mathfrak{g} \), and the \( \mathbb{Z} \)-lattice \( V = V \cap \mathfrak{h} \) is admissible [Bor70, Definition
with respect to this form (the admissibility follows from [Bor70, Proposition 2.6]). Define $G$ as the Zariski closure of $G$ in $\text{GL}(V)$. The $\mathbb{Z}$-group scheme $G$ has generic fibre $G$ and acts faithfully on the free $\mathbb{Z}$-module $V$.

Let $H$ be the unique split reductive group over $\mathbb{Z}$ extending $H$. The automorphism $\theta : H \to H$ extends by the same formula to an automorphism $H \to H$, still denoted by $\theta$.

Lemma 7.1. 1. $G$ is a split reductive group over $\mathbb{Z}$.

2. The equality $(H^0)^\circ = G$ extends to an isomorphism $(H^0_{\mathbb{Z}[1/2]})^\circ \simeq \widetilde{G}_{[1/2]}$, where $(H^0_{\mathbb{Z}[1/2]})^\circ$ is the relative identity component of $H^0_{\mathbb{Z}[1/2]}$.

Proof. For the first claim, since $G$ is $\mathbb{Q}$-split it suffices to prove that $G \to \text{Spec } \mathbb{Z}$ is smooth and affine and that its geometric fibres are connected reductive groups. But $G$ is $\mathbb{Z}$-flat and affine by construction, and its geometric fibres are reductive by [Bor70, §4.3]. The second claim follows from the fact that $(H^0_{\mathbb{Z}[1/2]})^\circ$ is a reductive group scheme of the same type as $G_{\mathbb{Z}[1/2]}$, which follows from [Con14, Remark 3.1.5].

Recall from §3.7 that we have fixed polynomials $p_{d_1}, \ldots, p_{d_r} \in \mathbb{Q}[V]^G$ satisfying the conclusions of Proposition 3.13. Note that those conclusions are invariant under the $G_m$-action on $B$. By rescaling the polynomials $p_{d_i}$ using this $G_m$-action, we can assume they lie in $\mathbb{Z}[V]^G$. We may additionally assume that the discriminant $\Delta$ from §4.1 lies in $\mathbb{Z}[V]^G$.

We extend the family of curves given by the equation in Table 1 to the family $\mathcal{C} \to \mathcal{B}$ above $\mathcal{B}_{\mathbb{Z}}$. Taking invariants defines a map $\pi : \mathcal{V} \to \mathcal{B}$.

Proposition 7.2. $G$ has class number 1: $G(\mathbb{A}^\infty) = G(\mathbb{Q}) G(\mathbb{Z})$.

Proof. The group $G$ is the Zariski closure of $G$ in $\text{GL}(V)$ and in a suitable basis of $V$, $G$ contains a maximal $\mathbb{Q}$-split torus consisting of diagonal matrices in $\text{GL}(V)$. Therefore $G$ has class number 1 by [PR94, Theorem 8.11; Corollary 2] and the fact that $\mathbb{Q}$ has class number one.

7.2 Spreading out

Our constructions and theorems for $(G, V)$ of the previous chapters will continue to be valid over $\mathbb{Z}[1/N]$ for some appropriate choice of integer $N$, in a sense we will now explain.

Let us call a positive integer $N$ admissible if the following properties are satisfied (set $S := \mathbb{Z}[1/N]$):

1. Each prime dividing the order of the Weyl group of $H$ is a unit in $S$. (In particular, 2 is a unit in $S$.)
2. The zero locus $D_S \to \text{Spec } S$ of the discriminant $\Delta$ is flat and its smooth locus $D^1_S$ coincides with the regular locus of $D_S$. Moreover, the nonsmooth locus of $D_S \to \text{Spec } S$ is flat over $\text{Spec } S$.
3. The morphism $\mathcal{C}_S \to \mathcal{B}_S$ is smooth exactly above $\mathcal{B}^{[1]}_S$.
4. The affine curve $\mathcal{C}_S^0$ is a closed subscheme of $\mathcal{V}_S$ and the action map $\mathcal{C}_S \times \mathcal{C}_S^0 \to \mathcal{V}_S, (g, x) \mapsto g \cdot x$ is smooth.
5. For a field $k$ of characteristic not dividing $N$, $b \in D^1(k)$ if and only if every semisimple lift $v \in V_S(k)$ has centraliser $Z_H(v)$ of semisimple rank 1, if and only if the curve $C_b$ has a unique nodal singularity. In that case, the curve $C_b$ is geometrically integral.

6. There exist open subschemes $V^r_S \subset V^\reg_S \subset V_S$ such that if $k$ is a field of characteristic not dividing $N$ and $v \in V_S(k)$ then $v$ is regular if and only if $v \in V^\reg_S(k)$, and $v$ is regular semisimple if and only if $v \in V^r_S(k)$. Moreover, $V^r_S$ is the open subscheme defined by the vanishing of the discriminant polynomial $\Delta$ in $V_S$.

7. The morphism $\pi: V_S \to B_S$ is smooth exactly at $V^\reg_S$.

8. $S[V^r_S] = S[p_d, \ldots, p_d]$. The Kostant section $\kappa$ fixed in §3.7 extends to a section $\kappa: B_S \to V^\reg_S$ of $\pi$ satisfying the following property: for any $b \in B(\mathbb{Z}) \subset B_S(S)$, we have $\kappa_{N,b} \in V(\mathbb{Z})$. Moreover, each $G(\mathbb{Q})$-orbit of Kostant sections has a representative which satisfies the same property.

9. Let $B^1$ be the complement of the nonregular locus of $D$ in $B$. Then the action map $G_S \times B_S \to V^\reg_S$, $(g, b) \mapsto g \cdot \kappa_b$ is étale and its image contains $V^\reg_S|_{B^1}$.

10. Let $\tilde{J}^S \to B_S$ denote the relative generalised Jacobian of the family of integral curves $C_S|_{B^1_S} \to B^1_S$ [BLR90] §9.3, Theorem 1] and let $J^S \to B^1_S$ denote its restriction to $B^1_S$. Let $Z_S \to B_S$ be the centraliser of the Kostant section $\kappa$ in $C_S$. Then there is an isomorphism $\tilde{J}^S(S)[\mathbb{Z}] \simeq Z^S$ of finite étale group schemes over $B^1_S$ whose restriction to $B^r_S$ is the isomorphism of Proposition 3.24. It extends to an isomorphism $\tilde{J}^S[\mathbb{Z}][2] \simeq Z^S$.

11. The $B$-scheme $\tilde{J}$ constructed in §3 extends to a $B_S$-scheme $\tilde{J}_S \to B_S$ which is flat, projective, with geometrically integral fibres and whose restriction to $B^i_S$ is isomorphic to $\tilde{J}^S$. Moreover, $\tilde{J}_S \to S$ is smooth with geometrically integral fibres, and the smooth locus of the morphism $\tilde{J}_S \to B_S$ is an open subscheme of $\tilde{J}_S$ whose complement is $S$-fibrewise of codimension at least two.

12. The $G$-torsor $T \to J^S$ from §6.2 extends using the same definition to a $G_S$-torsor $T_S \to J^S_S$, and $T_S$ is Zariski locally trivial.

It might be possible to construct an explicit admissible integer for every pair $(G, V)$. We will content ourselves with the following:

**Proposition 7.3.** There exists an admissible integer $N$.

**Proof.** The proof is very similar to the proof of [Lag20b, Proposition 4.1]. It follows from the results of the previous chapters and the principle of spreading out [Poo17, §3.2]. We omit the details, but refer in each case to the corresponding property over $\mathbb{Q}$.

Properties 1 and 2 follow from spreading out; Property 3 follows from Lemma 3.14; Property 4 from the definition of $C^O$ in §6.7 and Part 6 of Proposition 3.18; Property 5 follows from Theorem 4.14; Property 6 follows from an argument similar to Property 5 of [Lag20b, Proposition 4.1]; Property 7 follows from Lemma 3.22; Property 8 follows from an argument similar to Property 4 of [Lag20b, Proposition 4.1]; Property 9 follows from Propositions 3.11 and 4.8; Property 10 follows from Proposition 3.21 and Theorem 4.14; Property 11 follows from Theorem 3.13; finally Property 12 follows from Theorem 6.13.

For the remainder of the paper, we fix an admissible integer $N$ and continue to write $S = \text{Spec } \mathbb{Z}[1/N]$. Moreover, to simplify notation, we will drop the subscript $(\_)_S$ and write $G, V, B, J, C \ldots$ for $G_S, V_S, B_S, J_S, C_S \ldots$.

Using these properties, we can extend our previous results to $S$-algebras rather than $\mathbb{Q}$-algebras. We mention in particular:
Proposition 7.4 (Analogue of Corollary 6.5). Let $R$ be an $S$-algebra and $b \in B^{rs}(R)$. Then we have a natural bijection of pointed sets:

$$G(R) \setminus V_b(R) \simeq \ker \left( H^1(R, J_b[2]) \to H^1(R, G) \right). \quad (7.2.1)$$

Proposition 7.5 (Analogue of Theorem 6.6). Let $R$ be a local $S$-algebra and $b \in B^{rs}(R)$. Then there is an injective map

$$\eta_b : J_b(R)/2J_b(R) \hookrightarrow G(R) \setminus V_b(R)$$

compatible with base change on $R$.

We are now ready to state the main theorem of this chapter whose proof will be given at the end of §7.5.

Write $E_p$ for the set of all $b \in B(Z_p)$ that lie in $B^{rs}(Q_p)$. It consists of those elements of $R(Z_p)$ of nonzero discriminant.

Theorem 7.6. Let $p$ be a prime not dividing $N$. Then for any $b \in E_p$, the image of the map

$$\eta_b : J_b(Q_p)/2J_b(Q_p) \to G(Q_p) \setminus V_b(Q_p)$$

from Theorem 6.6 is contained in the image of the map $V(Z_p) \to G(Q_p) \setminus V(Q_p)$.

7.3 Some stacks

For technical purposes related to the proof of Theorem 7.6 we need to introduce some stacks relevant to our setup. This can be seen as an attempt to ‘geometrise’ the set of $G$-orbits of $V$, and allows for more flexibility in glueing and descent arguments. Hopefully we soothe the reader by mentioning that we will not need any serious properties of stacks, and we mainly think of them as collections of groupoids where one can glue objects suitably. All stacks introduced in this paper are considered in the étale topology. Recall from §7.2 that we have fixed an admissible integer $N$ and we have set $S = \mathbb{Z}[1/N]$.

Definition 7.7. Let $BG = \text{[Spec } S/G\text{]}$ be the classifying stack of $G$. By definition, for any $S$-scheme $X$ the groupoid $BG(X)$ has as objects $G$-torsors over $X$. Morphisms are given by isomorphisms of $G$-torsors.

Definition 7.8. Let $M = [G \setminus V]$ be the quotient stack of $V$ by the natural $G$-action on $V$. By definition, for any $S$-scheme $X$ an object of $M(X)$ consists of a $G$-torsor $T \to X$ together with a $G$-equivariant morphism $\phi : T \to V$. A morphism between two objects $(T, \phi)$ and $(T', \phi')$ consists of an isomorphism $\alpha : T \to T'$ of $G$-torsors satisfying $\phi' \circ \alpha = \phi$.

Finally, recall that $Z \to B$ denotes the centraliser of the Kostant section $\kappa$, an extension of the group scheme of Definition 3.16 to $S$. Consider the quotient stack $[B/Z] \to B$, where $Z$ acts trivially on $B$. For any $B$-scheme $X$, an $X$-point of $[B/Z](X)$ consists of a $Z$-torsor on $X$.

These stacks come with a few natural maps between them:

- $M \to BG$: sends a pair $(T, \phi)$ to the $G$-torsor $T$.

- $M \to B$: sends a pair $(T \xrightarrow{\alpha} X, T \xrightarrow{\phi} V)$ to the unique morphism $X \xrightarrow{f} B$ fitting in the commutative diagram:

$$\begin{array}{ccc}
T & \xrightarrow{\phi} & V \\
\downarrow{\alpha} & & \downarrow{\pi} \\
X & \xrightarrow{f} & B
\end{array}$$

43
V orbits of \( \complement \) is finite and let \( b \) categories.

4.8. \( M \) The next lemma can be interpreted as a categorical version of Corollary 6.5. Since an object \( \varphi \) mapping \( G \times X \to V \) sends \( (g, x) \) to \( g \cdot v(x) \).

Proof. \( \) Let \( \text{Lemma 7.9} \). By the same reasoning as the proof of Lemma 7.10, it suffices to prove that \( B \) factors through \( B/Z \). The inclusion \( \text{Lemma 7.11} \).

\( \) There is a substack \( [B/Z] \hookrightarrow M \) obtained by ‘twisting’ the Kostant section. For any \( B \)-scheme \( X \), its image consists of those elements of \( M \) that are étale locally conjugate to \( \kappa_b \) (or rather to its image under \( V \to M \)).

If \( \mathcal{G} \) is a groupoid, we write \( \pi_0 \mathcal{G} \) for its set of isomorphism classes.

**Lemma 7.9.** Let \( b \) be an \( X \)-point of \( B \). The map \( V_b(X) \to M_b(X) \) induces a bijection between the \( G(X) \)-orbits of \( V_b(X) \) and elements of \( \pi_0(M_b(X)) \) that map to the trivial element in \( \pi_0(BG(X)) \).

**Proof.** This follows formally from the definitions. Indeed, if \( v, v' \in V_b(X) \) give rise to isomorphic elements \((G \times X, \phi_v)\) and \((G \times X, \phi_{v'})\) in \( M_b(X) \), then there exists an isomorphism \( G \times X \xrightarrow{\sim} G \times X \) of \( G \)-torsors mapping \( \phi_v \) to \( \phi_{v'} \). Such an isomorphism is defined by multiplying an element of \( G(X) \), so \( v \) and \( v' \) are \( G(X) \)-conjugate. The argument can be reversed, so we obtain an injection \( G(X)V_b(X) \to \pi_0(M_b(X)) \).

Since an object \( (T, \phi) \) of \( M_b(X) \) is isomorphic to \((G \times X, \phi_v)\) for some \( v \in V_b(X) \) if and only if \( T \) is the trivial torsor, we conclude.

The next lemma can be interpreted as a categorical version of Corollary \( \ref{cor:6.5} \).

**Lemma 7.10.** The inclusion \( [B/Z] \hookrightarrow M \) induces an isomorphism of stacks \( [B^{\text{rs}}/Z^{\text{rs}}] \simeq M^{\text{rs}} \) over \( B^{\text{rs}} \).

**Proof.** It suffices to prove that for any \( B \)-scheme \( X \) and \( b \in B^{\text{rs}}(X) \), every two objects in \( M_b(X) \) are étale locally isomorphic. (For then every object will be étale locally isomorphic to the Kostant section.) By passing to an étale extension, we may assume that these objects map to the trivial element in \( \pi_0(BG(X)) \). It therefore suffices to prove that every two elements of \( V_b^{\text{rs}}(X) \) are étale locally \( G(X) \)-conjugate. This is true, since \( G \times B^{\text{rs}} \to V^{\text{rs}} \) is smooth and surjective so has sections étale locally; see Part 9 of \( \ref{part:7.2} \).

Let \( \mathcal{M}^{\text{reg}} \subset M \) be the open substack whose \( X \)-points consist of those objects \((T, \phi) \) of \( M(X) \) such that \( \phi \) lands in the locus of regular elements \( V^{\text{reg}} \), and all morphisms between them. Note that the map \([B/Z] \to M\) factors through \( \mathcal{M}^{\text{reg}} \) by (a spreading out of) Part 2 of Proposition \( \ref{prop:3.11} \).

**Lemma 7.11.** The inclusion \( [B/Z] \hookrightarrow \mathcal{M}^{\text{reg}} \) induces an isomorphism of stacks \( [B^1/Z^1] \simeq \mathcal{M}^{\text{reg}}|_{B^1} \) over \( B^1 \).

**Proof.** By the same reasoning as the proof of Lemma \( \ref{lemma:7.10} \) it suffices to prove that \( G \times B^1 \to V^{1,\text{reg}} \) is smooth and surjective. This follows from Part 9 of \( \ref{part:7.2} \) which is a spreading out of Propositions \( \ref{prop:3.11} \) and \( \ref{lemma:4.8} \).

The next useful lemma is a purity result for the stack \( \mathcal{M} \).

**Lemma 7.12.** Let \( X \) be a regular integral 2-dimensional scheme, let \( U \subset X \) be an open subscheme whose complement is finite and let \( b \in B(X) \). Then the restriction \( M_b(X) \to M_b|_U(\mathcal{U}) \) is an equivalence of categories.

\( ^3 \) Assuming it is a set, which will always be the case in this paper.
Proof. We will use the following fact \cite{CTS79} Lemme 2.1(iii)] repeatedly: if $Y$ is an affine $X$-scheme of finite type, then restriction of sections $Y(X) \to Y(U)$ is bijective. To prove essential surjectivity, let $(T_U, T_U \overset{\phi_U}{\to} V_b)$ be an object of $\mathcal{M}_{b(v)}(U)$. By \cite{CTS79} Théorème 6.13], the $G$-torsor $T_U \to U$ extends to a $G$-torsor $T$ on $X$. By the fact above applied to $Y = V_b$, $\phi_U$ uniquely extends to a morphism $\phi: T \to V_b$. The uniqueness of $\phi$ guarantees that $\phi$ is $G$-equivariant. Since the scheme of isomorphisms $\text{Isom}_{\mathcal{M}(A, A')}$ between two objects of $\mathcal{M}_b(X)$ is $X$-affine, fully faithfulness follows from the fact applied to this isomorphism scheme.

\[\]

### 7.4 Orbits of square-free discriminant

In this subsection we study orbits of square-free discriminant, which will be useful in the proof of Theorem 7.4 Orbits of square-free discriminant

**Lemma 7.13.** Suppose that $b \in B(R)$ satisfies $\text{ord}_K(\Delta(b)) = 1$. Then $b_k \in D^1(k)$.

**Proof.** We may assume that $R$ is complete. Since $\Delta(b)$ reduces to $0 \in k$, we have $b_k \in D$. Since $\Delta(b)$ is a uniformiser of $R$, the quotient of the regular ring $\mathcal{H}_b(B_R, \mathcal{O}_{B_R}) = R[p_{d_1}, \ldots, p_{d_r}]$ by the maximal ideal $(p_{d_1}, \ldots, p_{d_r}, \Delta)$ is isomorphic to $k$. Therefore the elements $\{p_{d_1}, \ldots, p_{d_r}, \Delta\}$ form a regular system of parameters at $b_k$. Hence $D_R = \text{Spec } K[\{p_{d_i}\}] / (\Delta)$ is regular at $b_k$. We conclude that $b_k$ is a regular point of $D_R$. To prove the lemma, it suffices to prove that the regular locus of $D_R$ coincides with the smooth locus $D_R^1$ of $D_R \to \text{Spec } R$.

Indeed, let $Z \subset D$ be the nonsmooth locus of $D \to \text{Spec } S$, which coincides with the nonregular locus of $D$ and is $S$-flat by Part 2 of §7.2. Let $Z'$ be the nonregular locus of $D_R$, which is closed by the excellence of $R$. Since the smooth locus commutes with base change, $Z_R$ agrees with the nonsmooth locus of $D_R \to \text{Spec } R$. It therefore suffices to show that $Z_R = Z'$. Since every smooth point of $D_R \to \text{Spec } R$ is regular, $Z' \subset Z_R$. To prove the opposite inclusion, let $L$ be the prime subfield of $K$, in other words the residue field of the image of $\text{Spec } K \to \text{Spec } S$. Since $L$ is perfect, $Z_L$ is the nonregular locus of $D_L$ and every point of $D_L \setminus Z_L$ is geometrically regular. It follows that $Z_K$ is the nonregular locus of $D_K$ and so $Z_K = Z'_K$. Since $Z$ is $S$-flat by assumption, $Z_R$ is $R$-flat so $Z_K$ is dense in $Z_R$. Since $Z'$ contains the closure of $Z'_K = Z_K$ which is $Z_R$, we conclude that $Z_R \subset Z'$.

**Lemma 7.14.** Suppose that $b \in B(R)$ satisfies $\text{ord}_K(\Delta(b)) = 1$. Then the scheme $V_b$ is regular.

**Proof.** The idea of the proof is to reduce the statement to $\mathfrak{sl}_2$: this will be achieved by a sequence of standard but somewhat technical reduction steps. Since regularity can be checked after étale extensions and completion, we may assume that $R$ is complete and $k$ is separably closed. By Lemma 7.13, $b_k \in D^1(k)$. Let $v \in V_b(k)$ be a semisimple element. Then the centraliser $Z_H(v)$ is a reductive group of semisimple rank one (Part 5 of §7.2).

We claim that there exists a lift $\tilde{v} \in V(R)$ of $v$ such that $\tilde{v}_K \in V(K) \subset \mathfrak{h}(K)$ is semisimple and such that the group scheme $Z_H(\tilde{v}) \to \text{Spec } R$ is smooth with connected fibres. Indeed, let $\mathfrak{c} \subset V_b$ be a Cartan subspace containing $v$ (here we use the extension of Vinberg theory to positive characteristic of \cite{Lev09}). Let $x \in V(R)$ be a lift of some regular semisimple element in $\mathfrak{c}$. Then $x_K$ is regular semisimple (this being an open condition) and its centraliser $\mathfrak{c} := z_b(x) \subset V_R$ is a Cartan subspace lifting $\mathfrak{c}$. Since $k$ is separably closed, $\mathfrak{c}$ is a split Cartan subalgebra; since $R$ is complete the same is true for $\tilde{\mathfrak{c}}$. We may therefore choose an element $\tilde{v} \in \tilde{\mathfrak{c}}$ lifting $v$ that vanishes on the same roots of $\mathfrak{c}$ as $v$; this $\tilde{v}$ will satisfy the desired properties. The smoothness of the centraliser $L := Z_H(\tilde{v}) \to \text{Spec } R$ follows from \cite{Cot22} Theorem 1.1(1)]. The connectedness of the fibres follows from Lemma 2.2 whose proof continues to hold if the characteristic of $k$ is not a torsion prime
for \( \mathfrak{h} \), which is weaker than our assumption that the order of the Weyl group is invertible in \( k \) (Part 1 of §7.2).

The involution \( \theta : \mathfrak{h} \to \mathfrak{h} \) restricts to a stable involution of the Lie algebra \( \mathfrak{l} \) of \( L \) by [Tho13, Lemma 2.5]. We claim that the morphism of \( R \)-schemes \( G \times \mathfrak{d}^{\theta = -1} \to V_R, (g, x) \mapsto g \cdot x \) is smooth. Since the domain and target are \( R \)-flat, it suffices to check this \( R \)-fibrewise [DR73, (1.7.4)]. This then follows from [Tho13, Proposition 4.5] (noting that \( X^1 = \mathfrak{d}^{\theta = -1} \) in this case), whose proof continues to hold when the characteristic of \( k \) does not divide the order of the Weyl group of \( H \).

Let \( \mathfrak{l} \to L \to B_L := \mathfrak{l} / L \) be the GIT quotient and let \( \phi : B_L \to B \) the map induced by the inclusion \( \mathfrak{l} \subset \mathfrak{h} \). Since \( \phi \) is étale at \( \pi_{L}(v) \in B_{L}(k) \) (Lemma 2.3), the \( R \)-point \( b \in B(R) \) uniquely lifts to an \( R \)-point \( b_{L} \in B_{L}(R) \) satisfying \( b_{L,k} = \pi_{L}(v) \). Since \( b_{L} \) is open in the fibre \( \phi^{-1}(b) \), \( b_{L} := \pi_{L}^{-1}(b_{L}) \) is an open subscheme of \( \mathfrak{l} \). Using the previous paragraph, this implies that the action map \( m : G \times \mathfrak{d}^{\theta = -1} \to V_b \) is smooth. We claim that \( m \) is also surjective. By Part 9 of §7.2 the image of \( m \) contains the set \( V_{b_{L}}^{\mathrm{reg}} \) of regular elements (in the sense of Lie theory). The complement \( V_{b_{L}} \setminus V_{b_{L}}^{\mathrm{reg}} \) consists of the semisimple elements of the special fibre \( V_{b,k} \). Since all such semisimple elements are \( G(k) \)-conjugate and since the image of \( m \) contains \( v \), we conclude that \( m \) is surjective.

Since regularity is a smooth-local property [Sta18, Tag 036D], the smooth surjective morphism \( m \) shows that it suffices to prove that \( \mathfrak{d}^{\theta = -1} \) is a regular scheme. We now make \( m \) more explicit. Since \( 2 \) is invertible in \( R \) and since \( L \) is reductive of semisimple rank 1, \( \mathfrak{l} = Z(\mathfrak{l}) \oplus \mathfrak{d}^{\mathrm{der}} \), where \( Z(\mathfrak{l}) \) and \( \mathfrak{d}^{\mathrm{der}} \) are the centre and the derived subalgebra of \( \mathfrak{l} \) respectively. Since \( k \) is separably closed, \( \mathfrak{d}^{\mathrm{der}} \simeq \mathfrak{sl}_{2,R} \). We claim that any two stable involutions on \( \mathfrak{l} \) are étale locally conjugate. Indeed, the subscheme of elements of \( L \) mapping one such involution to another is smooth, so to prove that it has sections étale locally we merely have to show it surjects on \( \mathrm{Spec} \ R \), which follows from a spreading out of Lemma 2.11 (See [Lag20a, Proposition 5.6] for the proof of a similar statement.) Therefore we may assume that in the decomposition \( \mathfrak{l} \simeq Z(\mathfrak{l}) \oplus \mathfrak{sl}_{2,R} \), \( \theta \) corresponds to the standard stable involution \( \mathrm{Ad}((1,1)) \) of \( \mathfrak{sl}_{2,R} \) and to \(-1\) on \( Z(\mathfrak{l}) \). Moreover if \( \Delta L \) denotes the discriminant polynomial of \( \mathfrak{l} \) then \( \Delta_L(b_{L}) \) equals \( \Delta(b) \) up to a unit in \( R \) (Lemma 2.3). We may now calculate that \( \mathfrak{l}^{\theta = -1} \) is isomorphic to the scheme \( (xy = \Delta_L(b_{L})) \). This scheme is regular since \( \Delta(b) \) and hence \( \Delta_L(b_{L}) \) is a uniformiser of \( R \).

**Lemma 7.15.** Let \( b \in B(R) \) with \( \text{ord}_K(\Delta(b)) = 1 \). Then \( C_b \) is regular and its geometric special fibre is integral and has a unique singularity, which is a node. Moreover, the group scheme \( J^1_b \to \mathrm{Spec} \ R \) (where \( J^1 \) is introduced in §4.3) is the Néron model of its generic fibre.

**Proof.** By Lemma 7.14 the scheme \( V_b \) is regular. Moreover since \( C^0 \) is (the spreading out of) a transverse slice of the \( G \)-action on \( V \), the map \( G \times C^0_b \to V_b \) is smooth (Part 3 of §7.2). Since regularity is smooth-local, it follows that \( C^0_b \) is a regular scheme. Since \( C_b \) is smooth in a Zariski neigbourhood of the marked points \( \infty_{1,b} \), the scheme \( C_b \) is regular too. We have \( b_k \in D^1(k) \) by Lemma 7.13. Therefore the special fibre \( C_b \) is geometrically integral and has a unique nodal singularity (Part 5 of §7.2). The claim about \( J^1_b \) follows from the regularity of \( C_b \) and a result of Raynaud [BLR90, §9.5, Theorem 1].

The next theorem is not necessary for the proof of Theorem 7.6 but completely determines the integral orbits in the case of square-free discriminant and will be useful in §8.10 and Chapter 9.

**Theorem 7.16.** Let \( R \) be a discrete valuation ring in which \( N \) is a unit. Let \( K = \text{Frac} \ R \) and let \( \text{ord}_K : K^\times \to \mathbb{Z} \) be the normalised discrete valuation. Let \( b \in B(R) \) and suppose that \( \text{ord}_K \Delta(b) \leq 1 \). Then:

1. If \( x \in V_b(R) \), then \( Z_G(x)(K) = Z_G(x)(R) \).

2. The natural map \( \alpha : G(R) \setminus V_b(R) \to G(K) \setminus V_b(K) \) is injective and its image contains \( \eta_b((J_b(K)/J_b(K))) \).

3. If furthermore $R$ is complete and has finite residue field then the image of $\alpha$ equals $\eta_b(J_b(K)/2J_b(K))$.

Proof. If $\text{ord}_K \Delta(b) = 0$, $J_b$ is smooth and proper over $R$. Since $Z_G(x)$ is finite étale over $R$, the first part follows. By Proposition 7.13 and Lemma 7.17 below, $\alpha$ is injective. Proposition 7.9 and the equality $J_b(K) = J_b(R)$ implies that $\eta_b: J_b(K)/2J_b(K) \to G(K)\backslash V_b(K)$ factors through $G(R)\backslash V_b(R)$, so the second part follows. If $R$ is complete and the residue field $k$ is finite, the pointed sets $H^1(R, G)$ and $H^1(K, J_b)$ are trivial by [Mil80, III.3.11(a)] and Lang’s theorem. The third part then follows from the fact that the 2-descent map $J_b(R)/2J_b(R) \to H^1(R, J_b[2])$ is an isomorphism.

We now assume that $\text{ord}_K \Delta(b) = 1$. Then $b_k \in D^1(k)$ by Lemma 7.13. By Lemma 7.13, $C_b/R$ is regular, has geometrically integral fibres and its special fibre has a unique nodal singularity. By the same lemma the group scheme $J_b^1/R$ introduced in 4.3 is the Néron model of its generic fibre. Moreover we have an isomorphism $Z_b^1 \simeq J_b^1[2]$ of quasi-finite étale group schemes over $R$ by Theorem 4.11 (or rather its spreading out, Part 10 of §7.2).

By Lemmas 7.13 and 3.2 (and the spreading out of the latter, Part 7 of §7.2) the scheme $V_b$ is regular and the smooth locus of the morphism $V_b \to \text{Spec } R$ coincides with the locus $V_b^\text{reg}$ of regular elements of $V_b$ (this time in the sense of Lie theory). Since a section of a morphism between regular schemes lands in the smooth locus [BL90 §3.1, Proposition 2], we see that $V_b(R) = V_b^\text{reg}(R)$. By Part 9 of §7.2, the morphism $G \times \text{Spec } R \to V_b^\text{reg}(R), (g, b) \mapsto g \cdot v_b$ is a torsor under the group scheme $Z_b^1$ from 4.2. By Lemma 2.13 we obtain a bijection of pointed sets

$$G(R)\backslash V_b(R) = G(R)\backslash V_b^\text{reg}(R) \simeq \ker(H^1(R, J_b^1[2]) \to H^1(R, G)).$$

(7.4.1)

We now prove the first part of the theorem. Since $x \in V_b^\text{reg}(R)$ is étale locally $G$-conjugate to $\kappa_b$ by the previous paragraph, we may assume that $x = \kappa_b$. But then $Z_G(\kappa_b) = Z_b^1 \simeq J_b^1[2]$ and $J_b^1$ satisfies the Néron mapping property, so $J_b^1[2](R) = J_b^1[2](K)$.

To prove the remaining parts, note that the map $H^1(R, J_b^1[2]) \to H^1(K, J_b^1[2]))$ is injective (Lemma 7.14 below), so by (7.4.1) the map $G(R)\backslash V_b(R) \to G(K)\backslash V_b(K)$ is injective too. To show that the image of $G(R)\backslash V_b(R) \to G(K)\backslash V_b(K)$ contains $\eta_b(J_b(K)/2J_b(K))$, note that we have an exact sequence of smooth group schemes

$$0 \to J_b^1[2] \to J_b^1 \xrightarrow{2} J_b^1 \to 0,$$

since $J_b^1$ has connected fibres. This implies the existence of a commutative diagram:

$$\begin{array}{ccc}
J_b^1(R)/2J_b^1(R) & \xrightarrow{\cong} & J_b(K)/2J_b(K) \\
\downarrow & & \downarrow \\
H^1(R, J_b^1[2]) & \longrightarrow & H^1(K, J_b[2])
\end{array}$$

It therefore suffices to prove that every element in the image of the map $J_b^1(R)/2J_b^1(R) \to H^1(R, J_b^1[2])$ has trivial image in $H^1(R, G)$. This is true, since the pointed kernel of the map $H^1(R, G) \to H^1(K, G)$ is trivial (Proposition 2.16).

If $R$ has finite residue field then [Mil80 III.3.11(a)] and Lang’s theorem imply that $H^1(R, G) = \{1\}$. In this case the $G(R)$-orbits of $V_b(R)$ are in bijection with $H^1(R, J_b^1[2])$ by (7.4.1). The triviality of $H^1(R, J_b^1)$ (again by Lang’s theorem) shows that $H^1(R, J_b^1[2])$ is in bijection with $J_b^1(R)/2J_b^1(R) = J_b(K)/2J_b(K)$. This proves Part 3, completing the proof of the proposition. \qed
We claim that the complement of $X$ in $\mathcal{X}$ is a union of finitely many closed points. Indeed, by Lemma 7.15 and the fact that the discriminant of $b\mathcal{Q}_p$ is square-free, the group scheme $J^1_{b\mathcal{Q}_p} \to \mathcal{X}_{\mathcal{Q}_p}$ is a Néron model.

Proof of Theorem 7.6. Choose a relative curve $X \to \mathcal{X}$, a map $\mathcal{X} \to \mathcal{J}_{\mathcal{Z}_p}$ and a section $x \in \mathcal{X}(\mathcal{Z}_p)$ satisfying the conclusions of Corollary 7.19 and let $\mathcal{X}^1 = X^1 \cap \mathcal{J}_{\mathcal{Z}_p}$ be the open subscheme of $\mathcal{X}$ landing in $J^1_{\mathcal{Q}_p}$.

We claim that the complement of $\mathcal{X}^1$ in $\mathcal{X}$ is a union of finitely many closed points. Indeed, by Lemma 7.15 and the fact that the discriminant of $b\mathcal{Q}_p$ is square-free, the group scheme $J^1_{b\mathcal{Q}_p} \to \mathcal{X}_{\mathcal{Q}_p}$ is a Néron model.
of its generic fibre. By the Néron mapping property, the section $\mathcal{X}_{ζ_p} \to J_{1,ζ_p}^1$ must land in $J_{1,ζ_p}^1$. Since the discriminant of $\mathcal{X}$ is nonzero on the special fibre, it follows that $\mathcal{X}_{ζ_p}^1$ is nonempty. Combining the last two sentences and the fact that $\mathcal{X}_{ζ_p}$ is irreducible proves the claim.

To finish the proof, we will use the stacks introduced in §7.3. Pulling back the $J^1[2]$-torsor $J^1 \times_2 J^1$ along $\mathcal{X}^1 \to J^1$ and using the isomorphism $J^1[2] \simeq Z^1$, we obtain a $Z^1$-torsor on $\mathcal{X}^1$, which determines a point $\mathcal{X}^1 \to [B/Z]$. Postcomposing with the morphism $[B/Z] \to M$ determines a morphism $\mathcal{X}^1 \to M_{b,ζ}^1$. By Lemma 7.12 — and this is the key point — this morphism extends (uniquely) to a morphism $\mathcal{X} \to M_{b,ζ}^1$. Precomposing with $x \in \mathcal{X}(\mathbb{Z}_p)$ defines an object $A$ of $M_{b,ζ}(\mathbb{Z}_p)$, whose $\mathbb{Q}_p$-fibre corresponds to $\eta_b(P)$ via Lemma 7.9. Since $H^1(\mathbb{Z}_p, G) = \{1\}$ (Mil80 III.3.11(a) and Lang’s theorem), every $G$-torsor on Spec $\mathbb{Z}_p$ is trivial, so again by Lemma 7.9 the object $A$ of $M_{b,ζ}(\mathbb{Z}_p)$ arises from an element of $V_b(\mathbb{Z}_p)$. This proves that $\eta_b(P)$ has a representative in $V_b(\mathbb{Z}_p)$, completing the proof. □

7.6 Orbits over $\mathbb{Z}$

Recall that $B_p = B(\mathbb{Z}_p) \cap B^r(\mathbb{Q}_p)$ for all $p$. Define $\mathcal{E} := B(\mathbb{Z}) \cap B^r(\mathbb{Q})$. We state the following corollary, whose proof is completely analogous to the proof of [RT20 Corollary 5.8] and uses the fact that $\mathcal{G}$ has class number 1 (Proposition 7.2).

**Corollary 7.20.** Let $b_0 \in \mathcal{E}$. Then for each prime $p$ dividing $N$ we can find an open compact neighbourhood $W_p$ of $b_0$ in $\mathcal{E}_p$ and an integer $n_p \geq 0$ with the following property. Let $M = \prod_{p|N} p^{n_p}$. Then for all $b \in \mathcal{E} \cap \left( \prod_{p|N} W_p \right)$ and for all $y \in \text{Sel}_2(J_{M,b})$, the orbit $\eta_{M,b}(y) \in G(\mathbb{Q}) \setminus V_{M,b}(\mathbb{Q})$ contains an element of $V_{M,b}(\mathbb{Z})$.

This statement about integral representatives will be strong enough to obtain the main theorems in §8.

8 Geometry-of-numbers

In this chapter we will apply the counting techniques of Bhargava to provide estimates for the integral orbits of bounded height in the representation $(\mathcal{G}, \mathcal{V})$. We will follow the arguments of [Lag20a §6] very closely. We keep the notation from the previous chapters and continue to assume that $H$ is not of type $A_1$.

8.1 Heights

Recall that $\mathcal{B} = \text{Spec } \mathbb{Z}[p_{d_1}, \ldots, p_{d_r}]$ and that $\pi: \mathcal{V} \to \mathcal{B}$ denotes the morphism of taking invariants. For any $b \in B(\mathbb{R})$ we define the height of $b$ by the formula

$$\text{ht}(b) := \sup_{1 \leq i \leq r} |p_i(b)|^{1/i}.$$  

We define $\text{ht}(v) = \text{ht}(\pi(v))$ for any $v \in V(\mathbb{R})$. We have $\text{ht}(\lambda \cdot b) = |\lambda|\text{ht}(b)$ for all $\lambda \in \mathbb{R}$ and $b \in B(\mathbb{R})$. If $A$ is a subset of $V(\mathbb{R})$ or $B(\mathbb{R})$ and $X \in \mathbb{R}_{>0}$ we write $A_{<X} \subset A$ for the subset of elements of height $< X$. For every such $X$, the set $B(\mathbb{Z})_{<X}$ is finite.

The next lemma records a numerological fact, which implies that $B(\mathbb{Z})_{<X}$ has order of magnitude $X^{\dim V}$.

**Lemma 8.1.** We have $d_1 + \cdots + d_r = \dim_{\mathbb{Q}} V$. 

49
Proof. Recall from §3.1 that \( \Phi_H \) denotes a root system of \( H \). We prove the two equalities \( d_1 + \cdots + d_r = \frac{1}{2} \# \Phi_H + \text{rank } H = \dim V \). The first one is classical, see [Car72, Corollary 10.2.4]; the second one follows from [Tho13] Lemma 2.21 applied to \( x = 0 \). \( \square \)

8.2 Measures on \( G \)

Let \( \omega_C \) be a generator for the \( \mathbb{Q} \)-vector space of left-invariant top differential forms on \( G \) over \( \mathbb{Q} \). It is well-defined up to an element of \( \mathbb{Q}^\times \) and it determines Haar measures \( dg \) on \( G(\mathbb{R}) \) and \( G(\mathbb{Q}_p) \) for each prime \( p \).

Recall from §3.7 that \( m \) denotes the number of marked points of the family of curves \( C \to B \).

Proposition 8.2. The product \( \text{vol}(G(\mathbb{Z})\backslash G(\mathbb{R})) \cdot \prod_p \text{vol}(G(\mathbb{Z}_p)) \) converges absolutely and equals \( 2^m \), the Tamagawa number of \( G \).

Proof. Proposition 7.2 implies that the product equals the Tamagawa number \( \tau(G) \) of \( G \). By Proposition 8.2 the group \( G \) is semi-simple and its fundamental group has order \( 2^\# \pi_0(H^0) \); let \( G_{sc} \to G \) be its simply connected cover. The proof of Proposition 6.10 (more precisely the isomorphism between (6.5.3) and (6.5.4)) shows that \( \# \pi_0(H^0) \) has order \( 2^m-1 \). Now use the identities \( \tau(G) = 2^m \tau(G_{sc}) \) [Ono63, Theorem 2.1.1] and \( \tau(G_{sc}) = 1 \) [Lan66]. \( \square \)

We study the measure \( dg \) on \( G(\mathbb{R}) \) using the Iwasawa decomposition, after introducing some notation. Recall from §3.1 that we have fixed a maximal torus \( T \subset H \) with set of roots \( \Phi_H \). Moreover we have fixed a Borel subgroup \( P \) containing \( T \), which determines a root basis \( S_H \subset \Phi_H \) and a set of positive roots \( \Phi_H^+ \). Then \( T^0 \) is a maximal torus of \( G \) and \( P^0 \) a Borel subgroup of \( G \) [Ric82, Lemma 5.1]. Let \( \Phi_G = \Phi(G, T^0) \) be its set of roots, \( S_G = \{ b_1, \ldots, b_k \} \) the corresponding root basis and \( \Phi_G^\pm \) the subset of positive/negative roots. Fix, once and for all, a maximal compact subgroup \( K \subset G(\mathbb{R}) \). If \( N \) is the unipotent radical of \( P^0 \) we have a decomposition \( P^0 = T^0 N \subset G \). Let \( \bar{P} = T^0 N \subset G \) be the opposite Borel subgroup. Then the natural product maps

\[
\tilde{N}(\mathbb{R}) \times T^0(\mathbb{R})^\circ \times K \to G(\mathbb{R}), \quad T^0(\mathbb{R})^\circ \times \tilde{N}(\mathbb{R}) \times K \to G(\mathbb{R})
\]

are diffeomorphisms. If \( t \in T^0(\mathbb{R}) \), let \( \delta_G(t) = \prod_{\beta \in \Phi_G} \beta(t) = \det \text{Ad}(t)|_{\text{Lie } N(\mathbb{R})} \). The following result follows from well-known properties of the Iwasawa decomposition; see [Lan75, Chapter 3§1].

Lemma 8.3. Let \( dt, dn, dk \) be Haar measures on \( T^0(\mathbb{R})^\circ, \tilde{N}(\mathbb{R}), K \) respectively. Then the assignment

\[
f \mapsto \int_{t \in T^0(\mathbb{R})^\circ} \int_{n \in \tilde{N}(\mathbb{R})} \int_{k \in K} f(tnk) \, dk \, dn \, dt = \int_{t \in T^0(\mathbb{R})^\circ} \int_{n \in \tilde{N}(\mathbb{R})} \int_{k \in K} f(tnk) \delta_G(t)^{-1} \, dk \, dn \, dt
\]

defines a Haar measure on \( G(\mathbb{R}) \).

We now fix Haar measures on the groups \( T^0(\mathbb{R})^\circ, K \) and \( \tilde{N}(\mathbb{R}) \), as follows. We give \( T^0(\mathbb{R})^\circ \) the measure pulled back from the isomorphism \( \prod_{\beta \in S_G} \beta : T^0(\mathbb{R})^\circ \to \mathbb{R}^{\# S_G} \), where \( \mathbb{R}_{>0} \) gets its standard Haar measure \( d^\times \lambda = d\lambda / \lambda \). We give \( K \) the probability Haar measure. Finally we give \( \tilde{N}(\mathbb{R}) \) the unique Haar measure \( dn \) such that the Haar measure on \( G(\mathbb{R}) \) from Lemma 8.3 coincides with \( dg \).

8.3 Measures on \( V \)

Let \( \omega_V \) be a generator of the free rank one \( \mathbb{Z} \)-module of left-invariant top differential forms on \( V \). Then \( \omega_V \) is uniquely determined up to sign and it determines Haar measures \( dv \) on \( V(\mathbb{R}) \) and \( V(\mathbb{Q}_p) \) for every prime
p. We define the top form \( \omega_B = dp_{d_1} \wedge \cdots \wedge dp_{d_r} \) on \( \mathcal{B} \). It defines measures \( db \) on \( B(\mathbb{R}) \) and \( B(\mathbb{Q}_p) \) for every prime \( p \).

**Lemma 8.4.** There exists a unique rational number \( W_0 \in \mathbb{Q}^x \) with the following property. Let \( k/\mathbb{Q} \) be a field extension, let \( c \) a Cartan subalgebra of \( \mathfrak{h}_k \) contained in \( \mathfrak{v}_k \), and let \( \mu_c : G_k \times c \to \mathfrak{v}_k \) be the action map. Then \( \mu^* \omega = W_0 \sigma_G \wedge \pi^* \omega_B \).

**Proof.** The proof is identical to that of \([\text{Tho15}, \text{Proposition 2.13}]\). Here we use the fact that the sum of the invariants equals the dimension of the representation: \( d_1 + \cdots + d_r = \dim \mathfrak{v} \) (Lemma 8.1). \( \square \)

**Lemma 8.5.** Let \( W_0 \in \mathbb{Q}^x \) be the constant of Lemma 8.4. Then:

1. Let \( V(\mathbb{Z}_p)^{rs} := V(\mathbb{Z}_p) \cap V^{rs}(\mathbb{Q}_p) \) and define a function \( m_p : V(\mathbb{Z}_p)^{rs} \to \mathbb{R}_{\geq 0} \) by the formula
   \[
   m_p(v) = \frac{\sum_{v' \in G(\mathbb{Z}_p) \cap (G(\mathbb{Q}_p) \cdot v \cap V(\mathbb{Z}_p))} \# G(v') \cdot \omega_c}{\# G(v') \cdot \omega_c}.
   \]
   Then \( m_p \) is locally constant.

2. Let \( B(\mathbb{Z}_p)^{rs} := B(\mathbb{Z}_p) \cap B^{rs}(\mathbb{Q}_p) \) and let \( \psi_p : V(\mathbb{Z}_p)^{rs} \to \mathbb{R}_{\geq 0} \) be a bounded, locally constant function which satisfies \( \psi_p(v) = \psi_p(v') \) when \( v, v' \in V(\mathbb{Z}_p)^{rs} \) are conjugate under the action of \( G(\mathbb{Q}_p) \). Then we have the formula
   \[
   \int_{v \in V(\mathbb{Z}_p)^{rs}} \psi_p(v) dv = |W_0|_p \operatorname{vol}(G(\mathbb{Z}_p)) \int_{b \in B(\mathbb{Z}_p)^{rs}} \int_{g \in G(\mathbb{Q}_p) \setminus V(\mathbb{Z}_p)} \# G(v') \cdot \omega_c \cdot \psi_p(v) \cdot \frac{m_p(v)}{\# G(v') \cdot \omega_c} db.
   \]

**Proof.** The proof is identical to that of \([\text{RTIS}, \text{Proposition 3.3}]\), using Lemma 8.4. \( \square \)

### 8.4 Fundamental sets

Let \( K \subset G(\mathbb{R}) \) be the maximal compact subgroup fixed in \( \mathfrak{s} \). For any \( c \in \mathbb{R}_{>0} \), define \( T_c := \{ t \in T^0(\mathbb{R})^\circ \mid \forall \beta \in S_G, \beta(t) \leq c \} \). A **Siegel set** is, by definition, any subset \( \mathcal{G}_{\omega,c} := \omega \cdot T_c \cdot K \), where \( \omega \subset \hat{N}(\mathbb{R}) \) is a compact subset and \( c > 0 \).

**Proposition 8.6.**

1. For every \( \omega \subset \hat{N}(\mathbb{R}) \) and \( c > 0 \), the set
   \[
   \{ \gamma \in G(\mathbb{Z}) \mid \gamma \cdot \mathcal{G}_{\omega,c} \cap \mathcal{G}_{\omega,c} \neq \emptyset \}
   \]
   is finite.

2. We can choose \( \omega \subset \hat{N}(\mathbb{R}) \) and \( c > 0 \) such that \( G(\mathbb{Z}) \cdot \mathcal{G}_{\omega,c} = G(\mathbb{R}) \).

**Proof.** The first part follows from the Siegel property \([\text{Bor63}, \text{Corollaire 15.3}]\). By \([\text{PR04}, \text{Theorem 4.15}]\), the second part is reduced to proving that \( G(\mathbb{Q}) = P(\mathbb{Q}) \cdot G(\mathbb{Z}) \), which follows from \([\text{Bor63}, \text{§6, Lemma 1(b)}] \). \( \square \)

Fix \( \omega \subset \hat{N}(\mathbb{R}) \) and \( c > 0 \) so that \( \mathcal{G}_{\omega,c} \) satisfies the conclusions of Proposition 8.6. By enlarging \( \omega \), we may assume that \( \mathcal{G}_{\omega,c} \) is semialgebraic. We drop the subscripts and for the remainder of \( \S \S \) we write \( \mathcal{G} \) for this fixed Siegel set. The set \( \mathcal{G} \) will serve as a fundamental domain for the action of \( G(\mathbb{Z}) \) on \( G(\mathbb{R}) \).
A $G(\mathbb{Z})$-coset of $G(\mathbb{R})$ may be represented more than once in $S$, but by keeping track of the multiplicities this will not cause any problems. The surjective map $\varphi: S \to G(\mathbb{Z}) \setminus G(\mathbb{R})$ has finite fibres and if $g \in S$ we define 

$$\mu(g) := \# \varphi^{-1}(\varphi(g)).$$

The function $\mu: S \to \mathbb{N}$ is uniformly bounded by $\mu_{\text{max}} := \# \{ \gamma \in G(\mathbb{Z}) \mid \gamma \cap S \neq \emptyset \}$ and has semialgebraic fibres. By pushing forward measures via $\varphi$, we obtain the formula

$$\int_{g \in S} \mu(g)^{-1} dg = \text{vol}(G(\mathbb{Z}) \setminus G(\mathbb{R})). \quad (8.4.1)$$

We now construct special subsets of $V^{tr}(\mathbb{R})$ which serve as our fundamental domains for the action of $G(\mathbb{R})$ on $V^{tr}(\mathbb{R})$. By the same reasoning as in [Hab15, §2.9], we can find open subsets $L_1, \ldots, L_k$ of $\{ b \in B^{tr}(\mathbb{R}) \mid \text{ht}(b) = 1 \}$ and sections $s_i: L_i \to V(\mathbb{R})$ of the map $\pi: V \to B$ satisfying the following properties:

- For each $i$, $L_i$ is connected and semialgebraic and $s_i$ is a semialgebraic map with bounded image.
- Set $\Lambda = \mathbb{R}_{>0}$. Then we have an equality

$$V^{tr}(\mathbb{R}) = \bigcup_{i=1}^{k} G(\mathbb{R}) \cdot \Lambda \cdot s_i(L_i). \quad (8.4.2)$$

If $v \in s_i(L_i)$ let $r_i = \# Z_G(v) / G(\mathbb{R})$; this integer is independent of the choice of $v$. We record the following change-of-measure formula, which follows from Lemma 8.4.

**Lemma 8.7.** Let $f: V(\mathbb{R}) \to \mathbb{C}$ be a continuous function of compact support and $i \in \{1, \ldots, k\}$. Let $G_0 \subset G(\mathbb{R})$ be a measurable subset and let $m_\infty(v)$ be the cardinality of the fibre of the map $G_0 \times \Lambda \times L_i \to V(\mathbb{R}), (g, \lambda, l) \mapsto g \cdot \lambda \cdot s_i(l)$ above $v \in V(\mathbb{R})$. Then

$$\int_{v \in G_0 \cdot \Lambda \cdot s_i(L_i)} f(v)m_\infty(v) \, dv = |W_0| \int_{b \in \Lambda \cdot L_i} \int_{g \in G_0} f(g \cdot s_i(b)) \, dg \, db,$$

where $W_0 \in \mathbb{Q}^\times$ is the scalar of Lemma 8.4.

**8.5 Counting integral orbits of $V$**

For any $G(\mathbb{Z})$-invariant subset $A \subset V(\mathbb{Z})$, define

$$N(A, X) := \sum_{v \in G(\mathbb{Z}) \setminus A \subset X} \frac{1}{\# Z_G(v)(\mathbb{Z})}.$$  

(Recall that $A \subset X$ denotes the set of elements of $A$ of height $< X$.) Let $k$ be a field of characteristic not dividing $N$. We say an element $v \in V(k)$ with $b = \pi(v)$ is:

- $k$-reducible if $\Delta(b) = 0$ or if it is $G(k)$-conjugate to a Kostant section, and $k$-irreducible otherwise.
- $k$-soluble if $\Delta(b) \neq 0$ and $v$ lies in the image of the map $\eta_b: J_b(k)/2J_b(k) \to G(k) \setminus V_b(k)$ of Proposition 7.6.

For any $A \subset V(\mathbb{Z})$, write $A^{trr} \subset A$ for the subset of $\mathbb{Q}$-irreducible elements. Write $V(\mathbb{R})^{sol} \subset V(\mathbb{R})$ for the subset of $\mathbb{R}$-soluble elements. Write $g$ for the common arithmetic genus of the curves $C \to B$.  

52
Theorem 8.8. We have

\[ N((\mathbb{Q}(\mathbb{Z}))^{irr} \cap V(\mathbb{R}))^{vol}, X) = \frac{|W_0|}{2^g} \text{vol} (G(\mathbb{Z}) \setminus G(\mathbb{R})) \text{vol} (B(\mathbb{R})_{<X}) + o \left( X^{d(V)} \right), \]

where \( W_0 \in Q^* \) is the scalar of Lemma 8.4.

We first explain how to reduce Theorem 8.8 to Proposition 8.9. Recall that there exists \( G_m \)-actions on \( V \) and \( B \) such that the morphism \( \pi : V \to B \) is \( G_m \)-equivariant and that we write \( \Lambda = \mathbb{R}_{>0} \). By an argument identical to \[\text{[Lag20b, Lemma 5.5]}, the subset \( V(\mathbb{R})^{vol} \subset V(\mathbb{R}) \) is open and closed in the Euclidean topology. Therefore by discarding some of the subsets \( L_1, \ldots, L_k \) of \( \text{[8.4]} \) we may write \( V(\mathbb{R})^{vol} = \bigcup_{i \in J} G(\mathbb{R}) \cdot \Lambda \cdot s_i(L_i) \) for some \( J \subset \{1, \ldots, k\} \). Moreover for every \( b \in B(\mathbb{R}) \) we have equalities

\[ \# (G(\mathbb{R}) \setminus G(\mathbb{R})^{sol}) / \# Z_G(k_b)(\mathbb{R}) = \# (J_b(\mathbb{R}) / 2 J_b(\mathbb{R})) / \# J_b[2](\mathbb{R}) = 1/2^g, \]

where the first follows from the definition of \( \mathbb{R} \)-solubility and Proposition 3.21 and the second is a general fact about real abelian varieties. Therefore by the inclusion-exclusion principle, to prove Theorem 8.8 it suffices to prove the following proposition. (See \[\text{[Lag20b, §5.2]} \) for more details concerning this step.)

For any nonempty subset \( I \) of \( \{1, \ldots, k\} \), write \( L_I = \pi (\cap_{i \in I} G(\mathbb{R}) \cdot s_i(L_i)) \). Fix an \( i \in I \), write \( s_i \) for the restriction of \( s_i \) to \( L_I \) and write \( r_i \) for the section \( s_i \). (The section \( s_i \) may depend on \( i \) but the number \( r_i \) does not if \( L_I \) is nonempty.)

Proposition 8.9. In the above notation, let \( (L, s, r) \) be \( (L_I, s_i, r_i) \) for some \( I \subset \{1, \ldots, k\} \). Then

\[ N((G(\mathbb{R}) \cdot \Lambda \cdot s(L)) \cap \mathbb{Q}(\mathbb{Z})^{irr}, X) = \frac{|W_0|}{p} \text{vol} (G(\mathbb{Z}) \setminus G(\mathbb{R})) \text{vol} (G(\mathbb{R}) \cdot \Lambda \cdot L_{<X}) + o \left( X^{d(V)} \right). \]

So to prove Theorem 8.8 it remains to prove Proposition 8.9. For the latter we will follow the general orbit-counting techniques established by Bhargava, Shankar and Gross \[\text{[BSS15, BGI13]} \) closely. The only notable differences are that we work with a Siegel set instead of a true fundamental domain and that we have to carry out a case-by-case analysis for cutting off the cusp in \[\text{§8.11} \) For the remainder of \[§8 \) we fix a triple \( (L, s, r) \) as above with \( L \neq \emptyset \).

8.6 First reductions

We first reduce Proposition 8.9 to estimating the number of (weighted) lattice points in a region of \( V(\mathbb{R}) \). Recall that \( \mathcal{S} \) denotes the Siegel set fixed in \[\text{§8.4} \) which comes with a multiplicity function \( \mu : \mathcal{S} \to \mathbb{N} \). Because \( G(\mathbb{Z}) \cdot \mathcal{S} = G(\mathbb{R}) \), every element of \( G(\mathbb{R}) \cdot \Lambda \cdot s(L) \) is \( G(\mathbb{Z}) \)-equivalent to an element of \( \mathcal{S} \cdot \Lambda \cdot s(L) \). In fact, we can be more precise about how often a \( G(\mathbb{Z}) \)-orbit will be represented in \( \mathcal{S} \cdot \Lambda \cdot s(L) \). Let \( \nu : \mathcal{S} \cdot \Lambda \cdot s(L) \to \mathbb{R}_{>0} \) be the ‘weight’ function defined by

\[ x \mapsto \nu(x) := \sum_{g \in \mathcal{S} \cdot \Lambda \cdot s(L)} \mu(g)^{-1}. \]

Then \( \nu \) takes only finitely many values and has semialgebraic fibres. We now claim that if every element of \( \mathcal{S} \cdot \Lambda \cdot s(L) \) is weighted by \( \nu \), then the \( G(\mathbb{Z}) \)-orbit of an element \( x \in G(\mathbb{R}) \cdot \Lambda \cdot s(L) \) is represented exactly \( \# Z_G(x)(\mathbb{R}) / \# Z_G(x)(\mathbb{Z}) \) times. More precisely, for any \( x \in G(\mathbb{R}) \cdot \Lambda \cdot s(L) \) we have

\[ \sum_{x' \in G(\mathbb{Z}) \cdot x \cap \mathcal{S} \cdot \Lambda \cdot s(L)} \nu(x') = \frac{\# Z_G(x)(\mathbb{R})}{\# Z_G(x)(\mathbb{Z})}. \]
This follows from an argument similar to [BS15a, p. 202] by additionally keeping track of the multiplicity function $\mu$.

In conclusion, for any $G(\mathbb{Z})$-invariant subset $A \subset V(\mathbb{Z}) \cap G(\mathbb{R}) \cdot \Lambda \cdot s(L)$ we have
\[ N(A, X) = \frac{1}{r} \# [A \cap (\mathfrak{S} \cdot \Lambda \cdot s(L))_{< X}], \tag{8.6.3} \]
with the caveat that elements on the right-hand side are weighted by $\nu$. (Recall that $r = \#Z_G(v)(\mathbb{R})$ for some $v \in s(L)$.)

### 8.7 Averaging and counting lattice points

We consider an averaged version of (8.6.3) and obtain a useful expression for $N(A, X)$ (Lemma 8.10) using a trick due to Bhargava. Then we use this expression to count orbits lying in the 'main body' of $V$ using geometry-of-numbers techniques, see Proposition 8.13.

Fix a compact, semialgebraic subset $G_0 \subset G(\mathbb{R}) \times \Lambda$ of nonempty interior, that in addition satisfies $K \cdot G_0 = G_0$, $\text{vol}(G_0) = 1$ and the projection of $G_0$ onto $\Lambda$ is contained in $[1, K_0]$ for some $K_0 > 1$. Moreover we suppose that $G_0$ is of the form $G_0^0 \times [1, K_0]$ where $G_0^0$ is a subset of $G(\mathbb{R})$. Equation (8.6.3) still holds when $L$ is replaced by $hL$ for any $h \in G(\mathbb{R})$, by the same argument as above. Thus for any $G(\mathbb{Z})$-invariant $A \subset V(\mathbb{Z}) \cap G(\mathbb{R}) \cdot \Lambda \cdot s(L)$ we obtain
\[ N(A, X) = \frac{1}{r} \int_{h \in G_0} \# [A \cap (\mathfrak{S} \cdot \Lambda \cdot hs(L))_{< X}] \, dh, \tag{8.7.1} \]
again with the caveat that elements on the right are weighted by a function similar to (8.6.1). We use Equation (8.7.1) to define $N(A, X)$ for any subset $A \subset V(\mathbb{Z}) \cap G(\mathbb{R}) \cdot \Lambda \cdot s(L)$ which is not necessarily $G(\mathbb{Z})$-invariant. We can rewrite this integral using the decomposition $\mathfrak{S} = \omega \cdot T_c \cdot K$, Lemma 8.3 and an argument similar to [BS15a, §2.3], which we omit.

**Lemma 8.10.** Given $X \geq 1$, $n \in \mathbb{N}(\mathbb{R})$, $t \in T^0(\mathbb{R})$ and $\lambda \in \Lambda$, define $B(n, t, \lambda, X) := (nt\lambda G_0 \cdot s(L))_{< X}$. Then for any subset $A \subset V(\mathbb{Z}) \cap (G(\mathbb{R}) \cdot \Lambda \cdot s(L))$ we have
\[ N(A, X) = \frac{1}{r} \int_{\lambda = K_0^{-1}}^{X} \int_{t \in T_c} \int_{n \in \omega} \# [A \cap B(n, t, \lambda, X)] \mu(nt)^{-1} \delta_G(t)^{-1} \, dn \, dt \, d^\omega \lambda, \tag{8.7.2} \]
where an element $v \in A \cap B(n, t, \lambda, X)$ on the right-hand side is counted with weight $\#\{h \in G_0 \mid v \in nt\lambda h \cdot s(L)\}$.

Before estimating the integrand of (8.7.2) by counting lattice points in the bounded regions $B(n, t, \lambda, X)$, we first need to handle the so-called cuspidal region after introducing some notation.

Let $\Phi_V$ be the set of weights of the $T^0$-action on $V$. Any $v \in V(\mathbb{Q})$ can be decomposed as $\sum v_a$ where $v_a$ lies in the weight space corresponding to $a \in \Phi_V$. For a subset $M \subset \Phi_V$, let $V(M) \subset V$ be the subspace of elements $v$ with $v_a = 0$ for all $a \in M$. Define $S(M) := V(M)(\mathbb{Q}) \cap V(\mathbb{Z})$.

Let $a_0 \in X^*(T^0)$ denote the restriction of the highest root $\alpha_0 \in \Phi_H$ to $T^0$. It turns out that $a_0 \in \Phi_V$: if $H$ is not of type $A_{2n}$, this follows from the fact that the Coxeter number of $H$ is even so the root height of $\alpha_0$ with respect to $S_H$ is odd; if $H$ is of type $A_{2n}$, this can be checked explicitly.

We define $S(\{a_0\})$ (sometimes written $S(a_0)$) as the cuspidal region and $V(\mathbb{Z}) \setminus S(a_0)$ as the main body of $V$. The next proposition, proved in [BS15a] says that the number of irreducible elements in the cuspidal region is negligible.
Proposition 8.11. There exists $\delta > 0$ such that $N(S(a_0)^{ Irr}, X) = O(X^{\dim V - \delta})$.

Having dealt with the cuspidal region, we may now count lattice points in the main body using the following proposition [BW14 Theorem 1.3], which strengthens a well-known result of Davenport [Dav51]. We prefer to cite [BW14] since the possibility of applying [Dav51] to a general semialgebraic set rests implicitly on the Tarski–Seidenberg principle (see [Dav64]).

Proposition 8.12. Let $m, n \geq 1$ be integers, and let $Z \subseteq \mathbb{R}^{m+n}$ be a semialgebraic subset. For $T \subseteq \mathbb{R}^m$, let $Z_T = \{x \in \mathbb{R}^n \mid (T, x) \in Z\}$, and suppose that all such subsets $Z_T$ are bounded. Then for any unipotent upper-triangular matrix $u \in \text{GL}_n(\mathbb{R})$, we have

$$\#(Z_T \cap u\mathbb{Z}^n) = \text{vol}(Z_T) + O(\max\{1, \text{vol}(Z_{T,j})\}),$$

where $Z_{T,j}$ runs over all orthogonal projections of $Z_T$ to all $j$-dimensional coordinate hyperplanes ($1 \leq j \leq n - 1$). Moreover, the implied constant depends only on $Z$.

Proposition 8.13. Let $A = \{V(z) \cap (G(\mathbb{R}) \cdot \Lambda \cdot s(L))\}$. Then

$$N(A \setminus S(a_0), X) = \frac{|W_0|}{r} \text{vol}(G(\mathbb{Z})\backslash G(\mathbb{R})) \text{vol}((\Lambda \cdot L \cdot s(L)) + o(X^{\dim V}).$$

Proof. Choose generators for the weight space $W_\lambda$ (as a finite free $\mathbb{Z}$-module) for every $a \in \Phi_V$ and let $\|\cdot\|$ denote the supremum norm of $V(\mathbb{R})$ with respect to this choice of basis. Since the set $\omega \cdot G_0 \cdot s(L)$ is bounded, we can choose a constant $J > 0$ such that $\|v\| \leq J$ for all $v \in \omega \cdot G_0 \cdot s(L)$. Let $F(n, t, \lambda, X) = \{v \in B(n, t, \lambda, X) \mid v_{n_0} \neq 0\}$. If $F(n, t, \lambda, X) \cap V(z) \neq \emptyset$, there exists an element $v \in B(n, t, \lambda, X)$ such that $\|v_{n_0}\| \geq 1$, hence $\lambda_0(t) \geq 1/J$.

We wish to estimate $\#(\{A \setminus S(a_0)\} \cap B(n, t, \lambda, X)) = \#(V(z) \cap F(n, t, \lambda, X))$ for all $t \in T_c, n \in \omega, \lambda \geq K_0^{-1}$ and $X$ using Proposition [8.12]. An element $v \in F(n, t, \lambda, X)$ has weight $\#(\{h \in G_0 \mid v \in nt\Omega \cdot s(L)\})$, and $F(n, t, \lambda, X)$ is partitioned into finitely many bounded semialgebraic subsets of constant weight. Moreover we have an equality of (weighted) volumes $\text{vol}(F(n, t, \lambda, X)) = \text{vol}(B(n, t, \lambda, X))$. Since $t$ and $\lambda$ stretch the elements of $V(z)$ by a factor $a(t)$ and $\lambda$ respectively, for any $M \subseteq \Phi_V$ the volume of the projection of $F(n, t, \lambda, X)$ to $V(M)(\mathbb{R})$ is bounded above by $O\left(\lambda^{\dim V - \# M} \prod_{a \in \Phi_V \setminus M} a(t)\right)$. Since $\Phi_V$ is closed under inversion, we have $\prod_{a \in \Phi_V} a(t) = 1$. Moreover since $a_0$ is the highest weight of the representation $V$, we know that for every $a \in \Phi_V$ we can write $a = a_0 - \sum_{\beta \in S_0} n_\beta \beta$ for some nonnegative rationals $n_\beta$. Since $t \in T_c$ by assumption, we have $a(t) \geq c^{-\sum n_\beta a_0(t)}$. It follows that

$$\lambda^{\dim V - \# M} \prod_{a \in \Phi_V \setminus M} a(t) = \lambda^{\dim V - \# M} \prod_{a \in M} a(t) = \lambda^{\dim V - \# M} a(t)^{-1} \ll \lambda^{\dim V - \# M} a_0(t)^{-\# M}.$$

Putting the results from the previous paragraph together, we conclude by Proposition [8.12] that the number of weighted elements of $\{(A \setminus S(a_0)) \cap B(n, t, \lambda, X)\}$ is given by:

$$\begin{cases}0 & \text{if } \lambda_0(t) < 1/J, \\
\text{vol}(B(n, t, \lambda, X)) + O(\lambda^{\dim V - 1} a_0(t)^{-1}) & \text{otherwise.}
\end{cases}$$

By that same proposition, the implied constant in this estimate is independent of $t \in T_c, n \in \omega, \lambda \geq K_0^{-1}$ and $X$. Therefore by Lemma [8.10], $N(A \setminus S(a_0), X)$ equals

$$\frac{1}{r} \int_{\lambda=K_0^{-1}} \int_{t \in T_c, a_0(t) \geq 1/J} \int_{n \in \omega} \int_{\lambda_{\Omega}} (\text{vol}(B(n, t, \lambda, X)) + O(\lambda^{\dim V - 1} a_0(t)^{-1})) \mu(nt)^{-1} \delta_{\Omega}(t)^{-1} \, dn \, dt \, d^X \lambda.$$

(8.7.3)
We first show that the integral of the second summand is \( o(X^{\dim V}) \). One easily reduces to showing that

\[
\int_{\lambda=K_\lambda^{-1}}^{X} \int_{\ell \in T_c, a_0(t) \geq 1/\lambda J} \lambda^{\dim V - 1} a_0(t)^{-1} \delta_C(t)^{-1} \, dt \, d^\times \lambda = o(X^{\dim V}). \tag{8.7.4}
\]

Write \( S_G = \{ \beta_1, \ldots, \beta_k \} \) and identify \( T^d(\mathbb{R}) \) with \( \mathbb{R}_+^k \) using the isomorphism \( t \mapsto (\beta_i(t)) \). Write \( a_0 = \sum h_i \beta_i \) and \( \sum \Phi^2 \beta = \sum \delta_i \beta_i \) with \( h_i, \delta_i \in \mathbb{Q} \). Since the coefficients \( \delta_i \) are strictly positive, there exists an \( 0 < \epsilon < 1 \) such that \( \delta_i - \epsilon h_i > 0 \) for all \( i \). Since \( \lambda^{1-\epsilon} a_0(t)^{1-\epsilon} \gg 1 \) on \( \{ t \in T_c : a_0(t) \geq 1/\lambda J \} \), it follows that

\[
\int_{\lambda=K_\lambda^{-1}}^{X} \int_{\ell \in T_c, a_0(t) \geq 1/\lambda J} \lambda^{\dim V - 1} a_0(t)^{-1} \delta_C(t)^{-1} \, dt \, d^\times \lambda \ll \int_{\lambda=K_\lambda^{-1}}^{X} \lambda^{\dim V - \epsilon} \int_{\ell \in T_c, a_0(t) \geq 1/\lambda J} a_0(t)^{-\epsilon} \delta_C(t)^{-1} \, dt \, d^\times \lambda. \tag{8.7.5}
\]

Since the exponents of \( t_i \) in \( a_0(t)^{1-\epsilon} \delta_C(t)^{-1} \) are strictly positive, the inner integral of the right-hand side of \( (8.7.5) \) is bounded independently of \( \lambda \). It follows that the right-hand side of \( (8.7.5) \) is \( \ll \int_{\lambda=K_\lambda^{-1}}^{X} \lambda^{\dim V - \epsilon} \, d^\times \lambda = O(X^{\dim V - \epsilon}) \), as claimed.

On the other hand, the integral of the first summand in \( (8.7.3) \) is

\[
\frac{1}{r} \int_{g \in \mathfrak{S}} \vol ((g \cdot \Lambda \cdot G_0 \cdot s(L))_{< X}) \mu(g)^{-1} \, dg + o(X^{\dim V}),
\]

using the fact that \( \vol(B(n, t, \lambda, X)) = O(\lambda^{\dim V}) \). Lemma \( 8.7 \) shows that

\[
\vol ((g \cdot \Lambda \cdot G_0 \cdot s(L))_{< X}) = |W_0| \vol ((\Lambda \cdot L)_{< X}) \vol(G_0) = |W_0| \vol ((\Lambda \cdot L)_{< X}).
\]

The proposition follows from Formula \( 8.4.1 \). \( \Box \)

### 8.8 End of the proof of Proposition 8.9

The following proposition is proven in \( 8.10 \).

**Proposition 8.14.** Let \( V^{\text{red}} \) denote the subset of \( \mathbb{Q} \)-reducible elements \( v \in V(\mathbb{Z}) \) with \( v \notin S(a_0) \). Then \( N(V^{\text{red}}, X) = o(X^{\dim V}) \).

We now finish the proof of Proposition \( 8.9 \) again. Let \( A = V(\mathbb{Z}) \cap (G(\mathbb{R}) \cdot \Lambda \cdot s(L)) \). Then

\[
N(A^{\text{irr}}, X) = N(A^{\text{irr}} \setminus S(a_0), X) + N(S(a_0)^{\text{irr}}, X)
\]

The second term on the right-hand side is \( o(X^{\dim V}) \) by Proposition \( 8.11 \) and \( N(A^{\text{irr}} \setminus S(a_0), X) = N(A \setminus S(a_0), X) + o(X^{\dim V}) \) by Proposition \( 8.14 \). Using Proposition \( 8.13 \), we obtain

\[
N(A^{\text{irr}}, X) = \frac{|W_0|}{r} \vol((G(\mathbb{Z}) \setminus G(\mathbb{R})) \vol((\Lambda \cdot L)_{< X}) + o(X^{\dim V}).
\]

This completes the proof of Proposition \( 8.9 \) hence also that of Theorem \( 8.8 \)

### 8.9 Congruence conditions

We now introduce a weighted version of Theorem \( 8.8 \). If \( w : V(\mathbb{Z}) \to \mathbb{R} \) is a function and \( A \subset V(\mathbb{Z}) \) is a \( \mathbb{Q}(\mathbb{Z}) \)-invariant subset we define

\[
N_w(A, X) := \sum_{v \in \mathbb{Q}(\mathbb{Z}) \setminus A \atop \text{ht}(v) < X} \frac{w(v)}{\#Z_{\mathbb{Q}}(v)(\mathbb{Z})}. \tag{8.9.1}
\]
We say a function $w$ is defined by finitely many congruence conditions if $w$ is obtained from pulling back a function $\tilde{w}: V(\mathbb{Z}/M\mathbb{Z}) \to \mathbb{R}$ along the projection $V(\mathbb{Z}) \to V(\mathbb{Z}/M\mathbb{Z})$ for some $M \geq 1$. For such a function write $\mu_w$ for the average of $\tilde{w}$ where we put the uniform measure on $V(\mathbb{Z}/M\mathbb{Z})$. The following theorem follows immediately from the proof of Theorem 8.8 compare [BS15a] §2.5.

**Theorem 8.15.** Let $w: V(\mathbb{Z}) \to \mathbb{R}$ be defined by finitely many congruence conditions. Then

$$N_w(V(\mathbb{Z})^{irr} \cap V^{sol}, X) = \mu_w \frac{\lvert W_0 \rvert}{2^g} \text{vol} (G(\mathbb{Z}) \setminus G(\mathbb{R})) \text{vol} (B(\mathbb{R})_{<X}) + o(X^{\dim V}),$$

where $W_0 \in \mathbb{Q}^\times$ is the scalar of Lemma 8.4.

Next we will consider infinitely many congruence conditions. Suppose we are given for each prime $p$ a $G(\mathbb{Z}_p)$-invariant function $w_p: V(\mathbb{Z}_p) \to [0,1]$ with the following properties:

- The function $w_p$ is locally constant outside the closed subset $\{ v \in V(\mathbb{Z}_p) \mid \Delta(v) = 0 \} \subset V(\mathbb{Z}_p)$.
- For $p$ sufficiently large, we have $w_p(v) = 1$ for all $v \in V(\mathbb{Z}_p)$ such that $p^2 \nmid \Delta(v)$.

In this case we can define a function $w: V(\mathbb{Z}) \to [0,1]$ by the formula $w(v) = \prod_p w_p(v)$ if $\Delta(v) \neq 0$ and $w(v) = 0$ otherwise. Call a function $w: V(\mathbb{Z}) \to [0,1]$ defined by this procedure acceptable.

**Theorem 8.16.** Let $w: V(\mathbb{Z}) \to [0,1]$ be an acceptable function. Then

$$N_w(V(\mathbb{Z})^{irr} \cap V^{sol}(\mathbb{R}), X) \leq \frac{\lvert W_0 \rvert}{2^g} \left( \prod_p \int_{V(\mathbb{Z}_p)} w_p(v) dv \right) \text{vol} (G(\mathbb{Z}) \setminus G(\mathbb{R})) \text{vol} (B(\mathbb{R})_{<X}) + o(X^{\dim V}).$$

**Proof.** This inequality follows from Theorem 8.15 the proof is identical to the first part of the proof of [BS15a] Theorem 2.21.

To obtain a lower bound in Theorem 8.16 when infinitely many congruence conditions are imposed, one needs a uniformity estimate that bounds the number of irreducible $G(\mathbb{Z})$-orbits whose discriminant is divisible by the square of a large prime. The following conjecture is the direct analogue of [BS15a] Theorem 2.13.

**Conjecture 8.17.** For a prime $p$, let $W_p(V)$ denote the subset of $v \in V(\mathbb{Z})^{irr}$ such that $p^2 \mid \Delta(v)$. Then for any $M > 0$, we have

$$\lim_{X \to +\infty} \frac{N(\cup_{p>M} W_p(V), X)}{X^{\dim V}} = O \left( \frac{1}{\log M} \right),$$

where the implied constant is independent of $M$.

Conjecture 8.17 is related to computing the density of square-free values of polynomials. See [Bha14a] for some remarks about similar questions, for known results and why these uniformity estimates seem difficult in general. By an identical proof to that of [BS15a] Theorem 2.21, we obtain:

**Proposition 8.18.** Assume that Conjecture 8.17 holds for $(G, V)$. Let $w: V(\mathbb{Z}) \to [0,1]$ be an acceptable function. Then

$$N_w(V(\mathbb{Z})^{irr} \cap V^{sol}(\mathbb{R}), X) = \frac{\lvert W_0 \rvert}{2^g} \left( \prod_p \int_{V(\mathbb{Z}_p)} w_p(v) dv \right) \text{vol} (G(\mathbb{Z}) \setminus G(\mathbb{R})) \text{vol} (B(\mathbb{R})_{<X}) + o(X^{\dim V}).$$

57
8.10 Estimates on reducibility and stabilisers

In this subsection we give the proof of Proposition 8.14 and the following proposition, which will be useful in §9.

Proposition 8.19. Let $V^{\text{bigstab}}$ denote the subset of $\mathbb{Q}$-irreducible elements $v \in V(\mathbb{Z})$ with $\#Z_G(v)(\mathbb{Q}) > 1$. Then $N(V^{\text{bigstab}}, X) = o(X^{\dim V})$.

By the same reasoning as [BG13 §10.7] it will suffice to prove Lemma 8.20 below, after having introduced some notation.

Let $N$ be the integer of §7.1 and let $p$ be a prime not dividing $N$. We define $V^{\text{reduced}}_p \subset V(\mathbb{Z}_p)$ to be the set of vectors whose reduction mod $p$ is $\mathbb{F}_p$-reducible. We define $V^{\text{bigstab}}_p \subset V(\mathbb{Z}_p)$ to be the set of vectors $v \in V(\mathbb{Z}_p)$ such that $p|\Delta(v)$ or the image of $v$ in $V(\mathbb{F}_p)$ has nontrivial stabiliser in $G(\mathbb{F}_p)$.

Lemma 8.20. We have

$$\lim_{Y \to +\infty} \prod_{N < p < Y} \int_{V^{\text{reduced}}_p} dv = 0,$$

and similarly

$$\lim_{Y \to +\infty} \prod_{N < p < Y} \int_{V^{\text{bigstab}}_p} dv = 0.$$

Proof. The proof is very similar to the proof of [RT20 Proposition 6.9] using the root lattice calculations of §3.9. We first treat the case of $V^{\text{bigstab}}_p$. Let $p$ be a prime not dividing $N$. We have the formula

$$\int_{V^{\text{bigstab}}_p} dv = \frac{1}{\#V(\mathbb{F}_p)} \#\{v \in V(\mathbb{F}_p) \mid \Delta(v) = 0 \text{ or } Z_G(v)(\mathbb{F}_p) \neq 1\}.$$

Since $\{\Delta = 0\}$ is a hypersurface we have

$$\frac{1}{\#V(\mathbb{F}_p)} \#\{v \in V(\mathbb{F}_p) \mid \Delta(v) = 0\} = O(p^{-1}). \tag{8.10.1}$$

If $v \in V^{\text{irred}}(\mathbb{F}_p)$ then $\#Z_G(v)(\mathbb{F}_p)$ depends only on $\pi(v)$ by (the $\mathbb{Z}[1/N]$-analogue of) Lemma 3.17. Therefore if $b \in B^{\text{ns}}(\mathbb{F}_p)$, Proposition 3.4 and Lang’s theorem imply that $\#V_b(\mathbb{F}_p)$ is partitioned into $\#H^1(\mathbb{F}_p, J_{b[2]})$ many orbits under $G(\mathbb{F}_p)$, each of size $\#G(\mathbb{F}_p)/\#J_{b[2]}(\mathbb{F}_p)$. Since $\#J_{b[2]}(\mathbb{F}_p) = \#(J_{b}(\mathbb{F}_p)/2J_{b}(\mathbb{F}_p)) = \#H^1(\mathbb{F}_p, J_{b[2]})$, we have $\#V^{\text{ns}}(\mathbb{F}_p) = \#G(\mathbb{F}_p)/\#B^{\text{ns}}(\mathbb{F}_p)$.

So to prove the lemma in case of $V^{\text{bigstab}}_p$ it suffices to prove that there exists a $0 < \delta < 1$ such that

$$\frac{1}{\#B^{\text{ns}}(\mathbb{F}_p)} \#\{b \in B^{\text{ns}}(\mathbb{F}_p) \mid J_{b[2]}(\mathbb{F}_p) \neq 1\} \to \delta$$

as $p \to +\infty$. We will achieve this using the results of [Ser12 §9.3]. Recall from §3.1 that $T$ is a split maximal torus of $H$ with Lie algebra $\mathfrak{t}$ and Weyl group $W$. These objects spread out to objects $T, H, \mathfrak{t}$ over $\mathbb{Z}$. In §3.9 we have defined a $W$-torsor $f : \mathfrak{t}^{\mathbb{A}} \to B^{\mathbb{A}}$ which extends to a $W$-torsor $\mathfrak{t}_p^{\mathbb{A}} \to B_p^{\mathbb{A}}$, still denoted by $f$. The group scheme $J[2] \to B_p^{\mathbb{A}}$ is trivialised along $f$ and the monodromy action is given by the natural action of $W$ on $N_L$ using the same logic and notation as Proposition 8.22. Let $C \subset W$ be the subset of elements of $W$ which fix some nonzero element of $N_L$. Then [Ser12 Proposition 9.15] implies that

$$\frac{1}{\#B^{\text{ns}}(\mathbb{F}_p)} \#\{b \in B^{\text{ns}}(\mathbb{F}_p) \mid J_{b[2]}(\mathbb{F}_p) \neq 1\} = \frac{\#C}{\#W} + O(p^{-1/2}). \tag{8.10.2}$$

58
Since $C \neq W$ by Part 3 of Proposition 3.23 we conclude the proof of the lemma in this case.

We now treat the case $V^\text{red}_p$. Again by (8.10.1) it suffices to prove that there exists a nonnegative $\delta < 1$ such that

$$\frac{1}{\#V^\text{ss}(\mathbb{F}_p)} \# \{ v \in V^\text{ss}(\mathbb{F}_p) \mid v \text{ is } \mathbb{F}_p\text{-reducible} \} < \delta \quad (8.10.3)$$

for all sufficiently large $p$. By the first paragraph of the proof of this lemma, there are exactly $\#J_p[2]$ orbits of $V_b(\mathbb{F}_p)$ for all $b \in B^\text{ss}(\mathbb{F}_p)$, each of size $\#G(\mathbb{F}_p)/\#J_p[2](\mathbb{F}_p)$. Therefore (8.10.3) equals

$$\frac{1}{\#B^\text{ss}(\mathbb{F}_p)} \sum_{b \in B^\text{ss}(\mathbb{F}_p)} \frac{\# \{ \mathbb{F}_p\text{-reducible orbits in } V_b(\mathbb{F}_p) \}}{\#J_p[2](\mathbb{F}_p)} \quad (8.10.4)$$

Each summand in (8.10.4) belongs to the set $\{ 1/2^{2g}, 2/2^{2g}, \ldots, (2^{2g} - 1)/2^{2g}, 1 \}$; let $\eta_p$ be the proportion of $b \in B^\text{ss}(\mathbb{F}_p)$ for which this summand equals 1. The the quantity in (8.10.3) is less than $\eta_p + (1 - \eta_p)(2^{2g} - 1)/2^{2g} = 1 + (\eta_p - 1)/2^{2g}$. By (8.10.2), $\eta_p \to \eta = 1 - \#C/\#W$ as $p$ tends to infinity. Since $1 \in C$, we see that $\eta < 1$ and hence $1 + (\eta - 1)/2^{2g} < 1$, completing the proof of the lemma.

**Proof of Proposition 8.14** We first claim that if $v \in V(\mathbb{Z})$ with $b = \pi(v)$ is $\mathbb{Q}$-reducible, then for each prime $p$ not dividing $N$ the reduction of $v$ in $V(\mathbb{F}_p)$ is $\mathbb{F}_p$-reducible. Indeed, either $\Delta(b) = 0$ in $\mathbb{F}_p$ (in which case $v$ is $\mathbb{F}_p$-reducible), or $p \mid \Delta(b)$ and $v$ is $G(\mathbb{Q})$-conjugate to $\kappa'_b \in J$ for some Kostant section $\kappa'$. In the latter case Part 2 of Theorem 7.16 implies that $v$ is $G(\mathbb{Z}_p)$-conjugate to $\kappa'_b$, so their reductions are $G(\mathbb{F}_p)$-conjugate, proving the claim. By a congruence version of Proposition 8.13 for every subset $L \subseteq B(\mathbb{R})$ considered in Proposition 8.19 and for every $Y > 0$ we obtain the estimate:

$$N(V^\text{red}_p \cap G(\mathbb{R}) \cdot L \cdot s(L), X) \leq C \prod_{N < p < Y} \int_{V^\text{red}_p} \frac{dv}{X^{\dim V} + o(X^{\dim V})},$$

where $C > 0$ is a constant independent of $Y$. By Lemma 8.20 the product of the integrals converges to zero as $Y$ tends to infinity, so $N(V^\text{red}_p \cap G(\mathbb{R}) \cdot L \cdot s(L), X) = o(X^{\dim V})$. Since this holds for every such subset $L$, the proof is complete.

**Proof of Proposition 8.19** Note that we have not used Theorem 8.8 in the proof of Proposition 8.13, but we may use it now to prove Proposition 8.19. Again the reduction of an element of $V^\text{bigstab}$ modulo $p$ lands in $V^\text{bigstab}$ if $p$ does not divide $N$. By Part 1 of Theorem 7.16 $\lim_{N \to +\infty} N(V^\text{bigstab}, X)/X^{\dim V}$ is $O(\prod_{N < p < Y} \int_{V^\text{red}_p} dv)$ by Theorem 8.13 and the product of the integrals converges to zero by Lemma 8.20, the proof is complete.

### 8.11 Cutting off the cusp

In this section we consider the only remaining unproved assertion of this chapter, namely Proposition 8.11. This is the only substantial part of this paper where we rely on previous papers treating specific cases. Case $A_{2g}$ is treated in [BG13 Proposition 10.5]; Case $A_{2g+1}$ ($g \geq 1$) is [SW13 Proposition 21]; Case $D_{2g+1}$ ($g \geq 2$) is [Sha19 Proposition 7.6]; Case $E_6$ is [Tho15 Proposition 3.6]; Case $E_7, E_8$ is [RT18 Proposition 4.5]. Note that these authors sometimes use a power of the height that we use. It remains to consider the case where $H$ is of type $D_{2n}$, and $n \geq 2$. We first reduce the statement to a combinatorial result, after introducing some notation. This reduction step is valid for any $H$, and we do not yet assume that $H$ is of type $D_{2n}$.
Recall that every element $a \in X^*(T^g) \otimes \mathbb{Q}$ can be uniquely written as $\sum_{i=1}^b n_i(a) \beta_i$ for some rational numbers $n_i(a)$. We define a partial ordering on $X^*(T^g) \otimes \mathbb{Q}$ by declaring that $a \succeq b$ if $n_i(a - b) \geq 0$ for all $i = 1, \ldots, k$. By restriction, this induces a partial ordering on $\Phi_V$. The restriction of the highest root $a_0 \in \Phi_V$ is the unique maximal element with respect to this partial ordering.

If $(M_0, M_1)$ is a pair of disjoint subsets of $\Phi_V$, we define $S(M_0, M_1) := \{v \in \mathbb{V}(\mathbb{Z}) \mid \forall a \in M_0, v_a = 0; \forall a \in M_1, v_a \neq 0\}$. Let $C$ be the collection of nonempty subsets $M_0 \subset \Phi_V$ with the property that if $a \in M_0$ and $b \succeq a$ then $b \in M_0$. Given a subset $M_0 \in C$ we define $\lambda(M_0) := \{a \in \Phi_V \setminus M_0 \mid M_0 \cup \{a\} \in C\}$, i.e. the set of maximal elements of $\Phi_V \setminus M_0$.

By definition of $C$ and $\lambda$ we see that $S(\{a_0\}) = \bigcup_{M_0 \in C} S(M_0, \lambda(M_0))$. Therefore to prove Proposition 8.11 it suffices to prove that for each $M_0 \in C$, either $S(M_0, \lambda(M_0))^{irr} = \emptyset$ or $N(S(M_0, \lambda(M_0)), X) = O(X^{\dim V - \epsilon})$ for some $\epsilon > 0$. By the same logic as [Tho15, Proposition 3.6 and §5] (itself based on a trick due to Bhargava), the latter estimate holds if there exists a subset $M_1 \subset \Phi_V \setminus M_0$ and a function $f : M_1 \to \mathbb{R}_{\geq 0}$ with $\sum_{a \in M_1} f(a) < \#M_0$ such that

$$\sum_{\beta \in \Phi^+_G} \beta - \sum_{a \in M_0} a + \sum_{a \in M_1} f(a) a$$

has strictly positive coordinates with respect to the basis $S_G$. It will thus suffice to prove the following combinatorial proposition, which is the analogue of [BG13, Proposition 29].

**Proposition 8.21.** Let $M_0 \in C$ be a subset such that $V(M_0)(\mathbb{Q})$ contains $\mathbb{Q}$-irreducible elements. Then there exists a subset $M_1 \subset \Phi_V \setminus M_0$ and a function $f : M_1 \to \mathbb{R}_{>0}$ satisfying the following conditions:

- We have $\sum_{a \in M_1} f(a) < \#M_0$.
- For each $i = 1, \ldots, k$ we have $\sum_{\beta \in \Phi^+_G} n_i(\beta) - \sum_{a \in M_0} n_i(a) + \sum_{a \in M_1} f(a) n_i(a) > 0$.

We will prove Proposition 8.21 in the remaining case $D_{2n}$ in Appendix A.

## 9 The average size of the 2-Selmer group

### 9.1 An upper bound

In this chapter we prove Theorem 12.3 stated in the introduction. Recall that we write $\mathcal{E}$ for the set of elements $b \in B(\mathbb{Z})$ of nonzero discriminant. We recall that we have defined a height function $ht$ for $\mathcal{E}$ in §8.1. We say a subset $\mathcal{F} \subset \mathcal{E}$ is defined by finitely many congruence conditions if $\mathcal{F}$ is the preimage of a subset of $\overline{B(\mathbb{Z}/n\mathbb{Z})}$ under the reduction map $\mathcal{E} \to B(\mathbb{Z}/n\mathbb{Z})$ for some $n \geq 1$.

**Theorem 9.1.** Let $\mathcal{F} \subset \mathcal{E}$ be a subset defined by finitely many congruence conditions. Let $m$ be the number of marked points. Then we have

$$\limsup_{X \to +\infty} \frac{\sum_{b \in \mathcal{F}, \text{ht}(b) < X} \# \text{Sel}_2 J_b}{\#\{b \in \mathcal{F} \mid \text{ht}(b) < X\}} \leq 3 \cdot 2^{m-1}.$$

The proof is along the same lines as the discussion in [RT20, §7].

We first prove a ‘local’ result. Recall that $\mathcal{E}_p$ denotes the set of elements $b \in B(\mathbb{Z}_p)$ of nonzero discriminant. Define $\mathcal{F}_p$ as the closure of $\mathcal{F}$ in $\mathcal{E}_p$, equivalently $\mathcal{F}_p$ is the preimage in $\mathcal{E}_p$ of a subset of $\overline{B(\mathbb{Z}/n\mathbb{Z})}$ that defines $\mathcal{F}$. 60
For every $b \in B^B(Q)$, consider the subgroup of $J_b(Q)/2J_b(Q)$ generated by differences of the marked points \{1 - \infty_2, \ldots, 1 - \infty_m\}. The image of this subgroup under the map $J_b(Q)/2J_b(Q) \to \text{Sel}_2 J_b$ is by definition the subgroup $\text{Sel}_2^{\text{irr}} J_b$ of ‘marked’ elements. Its complement $\text{Sel}_2^{\text{triv}} J_b$ is the subset of ‘nonmarked’ elements.

**Proposition 9.2.** Let $b_0 \in \mathcal{F}$. Then we can find for each prime $p$ dividing $N$ an open compact neighbourhood $W_p$ of $b_0$ in $\mathcal{E}_p$ such that the following condition holds. Let $\mathcal{F}_W = \mathcal{F} \cap \left( \prod_{p|N} W_p \right)$. Then we have

$$\limsup_{X \to +\infty} \sum_{b \in \mathcal{F}_W, \text{ht}(b) < X} \#\{b \in \mathcal{F}_W | \text{ht}(b) < X\} \# \text{Sel}_2^{\text{triv}} J_b \leq 2^m.$$  

**Proof.** Choose the sets $W_p$ and integers $n_p \geq 0$ for $p|N$ satisfying the conclusion of Corollary 7.20. If $p$ does not divide $N$, set $W_p = \mathcal{F}_p$ and $n_p = 0$. Let $M := \prod_p p^{n_p}$.

For $v \in V(Z)$ with $\pi(v) = b$, define $w(v) \in \mathbb{Q}_{\geq 0}$ by the following formula:

$$w(v) = \left\{ \begin{array}{ll} \sum_{v' \in \mathbb{Q}(Q) \setminus \mathbb{Q}(Q) \setminus V(Z)} \# \text{Sel}_2^{\text{irr}} J_b \quad & \text{if } b \in p^{n_p} \cdot W_p \text{ and } G(Q_p) \cdot v \in \eta_b(J_b(Q_p)/2J_b(Q_p)) \text{ for all } p, \\
0 & \text{otherwise.} \end{array} \right.$$ 

Define $w'(v)$ by the formula $w'(v) = \# Z_2(v)(Q) w(v)$. Corollaries 6.13 and 7.20 and Proposition 6.16 imply that if $b \in M \cdot \mathcal{F}_W$, nonmarked elements in the 2-Selmer group of $J_b$ correspond bijectively to $G(Q)$-orbits of $V_b(Q)$ that intersect $V(Z)$ nontrivially, that are $\mathbb{Q}$-irreducible and that are soluble at $\mathbb{R}$ and $\mathbb{Q}_p$ for all $p$.

In other words, in the notation of (8.9.1) we have the formula:

$$\sum_{b \in \mathcal{F}_W, \text{ht}(b) < X} \# \text{Sel}_2^{\text{irr}} J_b = \sum_{b \in M \cdot \mathcal{F}_W, \text{ht}(b) < MX} \# \text{Sel}_2^{\text{irr}} J_b = N_{w'}(V(Z)_{\text{irr}} \cap V(\mathbb{R})^{\text{sol}}, M X). \quad (9.1.1)$$

**Proposition 8.19** implies that

$$N_{w'}(V(Z)_{\text{irr}} \cap V(\mathbb{R})^{\text{sol}}, M X) = N_{w}(V(Z)_{\text{irr}} \cap V(\mathbb{R})^{\text{sol}}, M X) + o(X^{\dim V}). \quad (9.1.2)$$

It is more convenient to work with $w(v)$ than with $w'(v)$ because $w(v)$ is an acceptable function in the sense of 8.39. Indeed, for $v \in V(Z)$ with $\pi(v) = b$, define $w_p(v) \in \mathbb{Q}_{\geq 0}$ by the following formula

$$w_p(v) = \left\{ \begin{array}{ll} \sum_{v' \in \mathbb{Q}_p(\mathbb{Q}_p) \setminus \mathbb{Q}_p(\mathbb{Q}_p) \setminus V(\mathbb{Q}_p)} \# \text{Sel}_2^{\text{irr}} J_b \quad & \text{if } b \in p^{n_p} \cdot W_p \text{ and } G(Q_p) \cdot v \in \eta_b(J_b(Q_p)/2J_b(Q_p)), \\
0 & \text{otherwise.} \end{array} \right.$$ 

Then an argument identical to [BS15a] Proposition 3.6 (using that $G$ has class number 1 by Proposition 7.2) shows that $w(v) = \prod_p w_p(v)$ for all $v \in V(Z)$. The remaining properties for $w(v)$ to be acceptable follow from Part 1 of Lemma 8.5 and Theorem 7.16. Using Lemma 8.5 we obtain the formula

$$\int_{v \in V(\mathbb{Q}_p)} w_p(v) dv = |W_0|_{p} \text{ vol } (G(Q_p)) \int_{b \in p^{n_p} \cdot W_p} \frac{\# J_b(Q_p)/2J_b(Q_p)}{\# J_b(2)(Q_p)} db. \quad (9.1.3)$$

Using the equality $\# J_b(Q_p)/2J_b(Q_p) = [1/2^g]_p \# J_b(2)(Q_p)$ for all $b \in \mathcal{E}_p$ (which is a general fact about abelian varieties), we see that the integral on the right-hand side equals $[1/2^g]_p \text{ vol } (p^{n_p} \cdot W_p) = [1/2^g]_p p^{-n_p \dim V} \text{ vol } (W_p)$.

Combining the identities (9.1.1) and (9.1.2) shows that

$$\limsup_{X \to +\infty} X^{-\dim V} \sum_{b \in \mathcal{F}_W, \text{ht}(b) < X} \# \text{Sel}_2^{\text{triv}} J_b = \limsup_{X \to +\infty} X^{-\dim V} N_{w}(V(Z)_{\text{irr}} \cap V(\mathbb{R})^{\text{sol}}, M X).$$
This in turn by Theorem 8.16 is less than or equal to
\[
\frac{|W_0|}{2^g} \left( \prod_p \int_{\mathcal{L}(\mathbb{Z}_p)} w_p(v) dv \right) \text{vol}(G(\mathbb{Z}) \backslash G(\mathbb{R})) 2^{\dim B} M^{\dim V}.
\]

Using (9.1.3) this simplifies to
\[
\text{vol}(G(\mathbb{Z}) \backslash G(\mathbb{R})) \prod_p \text{vol}(G(\mathbb{Z}_p)) 2^{\dim B} \prod_p \text{vol}(W_p).
\]

On the other hand, an elementary point count shows that
\[
\lim_{X \to +\infty} \frac{\# \{ b \in F_W \mid ht(b) < X \}}{X^{\dim V}} = 2^{\dim B} \prod_p \text{vol}(W_p).
\]

We conclude that
\[
\limsup_{X \to +\infty} \frac{\sum_{b \in F_{W_i}, ht(b) < X} \# \text{Sel}_{2}^{\text{triv}} J_b}{\# \{ b \in F \mid ht(b) < X \}} \leq \text{vol}(G(\mathbb{Z}) \backslash G(\mathbb{R})) \cdot \prod_p \text{vol}(G(\mathbb{Z}_p)).
\]

Since the Tamagawa number of $G$ is $2^m$ (Proposition 8.2), the proposition follows.

To deduce Theorem 9.1 from Proposition 9.2, choose for each $i \geq 1$ sets $W_{p,i} \subset E_p$ (for $p$ dividing $N$) such that if $W_i = \mathcal{E} \cap \left( \prod_{p|N} W_{p,i} \right)$, then $W_i$ satisfies the conclusion of Proposition 9.2 and we have a countable partition $\mathcal{F} = F_{W_1} \cup F_{W_2} \cup \cdots$. By an argument identical to the proof of Theorem 7.1 in [RT20], we see that for any $\varepsilon > 0$, there exists $k \geq 1$ such that
\[
\limsup_{X \to +\infty} \frac{\sum_{b \in \bigcup_{i<k} F_{W_i}, ht(b) < X} \# \text{Sel}_{2}^{\text{triv}} J_b}{\# \{ b \in F \mid ht(b) < X \}} < \varepsilon.
\]

This implies that
\[
\limsup_{X \to +\infty} \frac{\sum_{b \in \mathcal{F}, ht(b) < X} \# \text{Sel}_{2}^{\text{triv}} J_b}{\# \{ b \in F \mid ht(b) < X \}} \leq 2^m \limsup_{X \to +\infty} \frac{\# \{ b \in \bigcup_{i<k} F_{W_i} \mid ht(b) < X \}}{\# \{ b \in F \mid ht(b) < X \}} + \varepsilon
\]
\[
\leq 2^m + \varepsilon.
\]

Since the above inequality is true for any $\varepsilon > 0$, it is true for $\varepsilon = 0$. Since the subgroup $\text{Sel}_{2}^{\text{triv}} J_b$ has size at most $2^{m-1}$, we conclude the proof of Theorem 9.1.

Remark 9.3. A small modification of the above argument shows that Theorem 9.1 remains valid when $\mathcal{F} \subset \mathcal{E}$ is the subset of so-called ‘minimal’ elements, namely those elements $b \in \mathcal{E}$ with $N^{-1} \cdot b \not\in B(\mathbb{Z})$ for all integers $N \geq 1$.

9.2 A conditional lower bound

We show that the upper bound in Theorem 9.1 is sharp if we assume Conjecture 8.17. We first need to establish (unconditionally) a lower bound for the subgroup of marked elements $\text{Sel}_{2}^{\text{triv}} J_b$.

Proposition 9.4. Let $\mathcal{F} \subset \mathcal{E}$ be a subset defined by finitely many congruence conditions. Then the limit
\[
\lim_{X \to +\infty} \frac{\# \{ b \in \mathcal{F} \mid ht(b) < X, \# \text{Sel}_{2}^{\text{triv}} J_b = 2^{m-1} \}}{\# \{ b \in \mathcal{F} \mid ht(b) < X \}}
\]
exists and equals $1$. 

62
It therefore suffices to prove that the limit
\[
\lim_{x \to +\infty} \frac{\#\{b \in \mathcal{F} \mid \text{ht}(b) < X, \text{Gal}(\mathbb{Q}^s | \mathbb{Q}) \to W \text{ surjective}\}}{\#\{b \in \mathcal{F} \mid \text{ht}(b) < X\}}
\]
even exists and equals 1. This follows from a version of Hilbert’s irreducibility theorem; see [Coh81, Theorem 2.1], adapted as in [Coh81, §5, Notes (iii)] to account for the fact that the coordinates of \( B \) have unequal weights.

**Theorem 9.5.** Assume that Conjecture 8.17 holds for \((G,V)\). Let \( \mathcal{F} \subset \mathcal{E} \) be a subset defined by finitely many congruence conditions. Then the limit
\[
\lim_{x \to +\infty} \frac{\sum_{b \in \mathcal{F}, \text{ht}(b) < X} \#\{\text{Sel}_2 J_b\}}{\#\{b \in \mathcal{F} \mid \text{ht}(b) < X\}}
\]
even exists and equals \( 2^m \). Moreover, the average size of the 2-Selmer group \( \text{Sel}_2 J_b \) exists and equals \( 3 \cdot 2^{m-1} \).

**Proof.** The proof of the first statement is identical to the proof of Theorem 9.1 using Proposition 8.18 instead of Theorem 8.16. The second statement follows from the first and Proposition 9.4.

## A Cutting off the cusp for \( D_{2n} \)

In this appendix chapter we prove Proposition 8.11 in the case that \( H \) is of type \( D_{2n} \) for all \( n \geq 2 \). The methods employed here are fairly standard but somewhat intricate, and are sometimes inspired by [Sha19, §7.2.1]. In §A.1 we recall some results and notation on groups of type \( D_n \). In §A.2 we make the representation \((G,V)\) in the case \( D_{2n} \) and some related objects explicit. In §A.3 we establish sufficient conditions for a vector \( v \in V(\mathbb{Q}) \) to be \( \mathbb{Q} \)-reducible. In §A.4 we finish the proof of Proposition 8.11.

### A.1 Recollections on even orthogonal groups

Let \( n \geq 2 \) be an integer. Let \( W \) be a \( 2n \)-dimensional \( \mathbb{Q} \)-vector space with basis \( \mathcal{B} = \{e_1, \ldots, e_n, e_n^*, \ldots, e_1^*\} \). Let \( b \) be the symmetric bilinear form with the property that \( b(e_i, e_j) = b(e_i^*, e_j^*) = 0 \) and \( b(e_i, e_j^*) = \delta_{ij} \) for all \( 1 \leq i, j \leq n \). For every linear map \( f : W \to W \), there is a unique adjoint linear map \( f^* : W \to W \) satisfying \( b(fv, w) = b(v, f^*w) \) for all \( v, w \in W \). We define the \( \mathbb{Q} \)-algebraic group \( H := \text{SO}(W,b) = \{g \in \text{SL}(W) \mid gg^* = 1\} \). Then \( \mathfrak{h} := \text{Lie} H \) can be naturally identified with \( \{f \in \text{End}(W) \mid f + f^* = 0\} \). Below we will make various aspects of the semisimple group \( H \) explicit.

Using \( \mathcal{B} \) to represent an element \( f : W \to W \) as a \((2n) \times (2n)\)-matrix \( A, \ f^* \) corresponds to reflecting \( A \) along its antidiagonal. Consider the maximal torus \( T = \{\text{diag}(t_1, \ldots, t_n, t_n^{-1}, \ldots, t_1^{-1})\} \subset H \). Its character group \( X^*(T) \) is freely generated by the characters \( (t_1, \ldots) \mapsto t_i \) with \( 1 \leq i \leq n \), and we abusively denote these characters by \( t_i \in X^*(T) \) too.
**Root system**  The roots of \( \mathfrak{h} \) with respect to \( T \) are given by

\[
\Phi_H = \{ \pm t_i \pm t_j \mid 1 \leq i \neq j \leq n \} \subset X^*(T). \tag{A.1.1}
\]

The standard upper triangular Borel subgroup of \( GL_{2n} \) (with respect to the basis \( \mathcal{B} \) of \( W \)) determines a root basis of \( \Phi_H \), given by

\[
S_H = \{ t_1 - t_2, \ldots, t_{n-1} - t_n, t_{n-1} + t_n \}. \tag{A.1.2}
\]

We denote the elements of this root basis by \( \alpha_1, \ldots, \alpha_n \). The highest root of \( \Phi_H \) with respect to \( S_H \) is \( t_1 + t_2 \), which has height \( 2n - 3 \).

**Weyl group**  The Weyl group \( W_H \) is isomorphic to \( S_n \times (Z/2Z)^{n-1} \). Explicitly, elements of \( W_H \) correspond to pairs \((\sigma, (\epsilon_i))\), where \( \sigma \in S_n \) is a permutation and \( \epsilon_i \in \{\pm 1\} \) is a sign for each \( 1 \leq i \leq n \), with the property that \( \prod \epsilon_i = 1 \). An element \((\sigma, (\epsilon_i))\) acts on \( X^*(T) \) via the rule \( t_i \mapsto \epsilon_i t_{\sigma(i)} \). In particular, \(-1 \in W_H \) if and only if \( n \) is even.

**Stable involution**  To describe the stable involution of \( H \) in \( \mathbf{A.2} \) in the case that \( n \) is even, we determine the elements \( s \in T \) with the property that \( \alpha(s) = -1 \) for every simple root \( \alpha \in S_H \). Such an \( s \) is not uniquely determined since \( H \) is not adjoint, but it is uniquely determined up to multiplication by the element \((-1, \ldots, -1) \in T \) of the centre of \( H \). Using the description \( \mathbf{A.1.2} \) we see that \( s \) is of the form

\[
\pm (1, -1, 1, -1, \ldots, (-1)^n). \tag{A.1.3}
\]

**Change of variables**  We record the following computation which will be useful in \( \mathbf{A.4} \)

\[
\begin{aligned}
t_i &= \alpha_i + \cdots + \alpha_{n-2} + \frac{1}{2}(\alpha_{n-1} + \alpha_n), \quad (1 \leq i \leq n - 2) \\
t_{n-1} &= \frac{1}{2}(\alpha_{n-1} + \alpha_n), \\
t_n &= \frac{1}{2}(\alpha_{n-1} + \alpha_n).
\end{aligned} \tag{A.1.4}
\]

**Sum of positive roots**  The sum of the positive roots of \( \Phi_H \) with respect to \( S_H \) is

\[
\sum_{\alpha \in \Phi_H^+} \alpha = 2(n-1)t_1 + 2(n-2)t_2 + \cdots + 2t_{n-1} \tag{A.1.5}
\]

\[
= \sum_{k=1}^{n-2} k(2n-k-1)\alpha_k + \frac{n(n-1)}{2}(\alpha_{n-1} + \alpha_n). \tag{A.1.6}
\]

**Discriminant**  Let \( t := \text{Lie} T \) and write an element of \( t \) as \( \text{diag}(t_1, \ldots, t_n, -t_n, \ldots, -t_1) \). Let \( \Delta \in \mathbb{Q}[h]^H \) be the discriminant polynomial of \( H \), defined as the image of \( \prod_{\alpha \in \Phi_H} \alpha \) under the Chevalley isomorphism \( \mathbb{Q}[t]^W_H \rightarrow \mathbb{Q}[h]^H \) of Proposition \( \mathbf{2.1} \). Let \( \text{Pff} \in \mathbb{Q}[h]^H \) be the image of the product \( \prod_{i=1}^n t_i \in k[t]^W_H \) under the Chevalley isomorphism. If we write \( t_i := t_{2n+1-i} \) for \( n+1 \leq i \leq 2n \), then we may compute that

\[
\prod_{1 \leq i < j \leq 2n} (t_i - t_j)^2 = \prod_{\alpha \in \Phi_H} \alpha(t)^2 \prod_{i=1}^n t_i^2. \tag{A.1.7}
\]

It follows that if we write \( \chi_v \) for the characteristic polynomial of a square matrix \( v \) and \( \text{disc}(\chi_v) \) for its discriminant, we have the identity

\[
\text{disc}(\chi_v) = \Delta(v)^2 \text{Pff}(v)^2 \tag{A.1.8}
\]

for every \( v \in \mathfrak{h} \).
A.2 An explicit model for the split stable involution of $D_{2n}$

Let $n \geq 2$ be an integer. Let $W_1$ be the $\mathbb{Q}$-vector space with basis $\{e_1, \ldots, e_n, e_1^*, \ldots, e_1^*\}$, and let $b_1$ be the symmetric bilinear form with the property that $b_1(e_i, e_j) = b_1(e_i^*, e_j^*) = 0$ and $b_1(e_i, e_j^*) = \delta_{ij}$ for all $1 \leq i, j \leq n$. Let $W_2$ be the $\mathbb{Q}$-vector space with basis $\{f_1, \ldots, f_n, f_1^*, \ldots, f_1^*\}$, and let $b_2$ be the bilinear form of $W_2$ constructed similarly to $b_1$ with $e_i$ and $e_i^*$ replaced by $f_1$ and $f_1^*$. Let $(W_1, b_1) \oplus (W_2, b_2)$. Let $H' := SO(W, b)$, let $H$ be the quotient of $H'$ by its centre of order 2 and let $\mathfrak{h} := \text{Lie} H = \text{Lie} H'$. With respect to the basis

$$\{e_1, \ldots, e_n, e_1^*, \ldots, e_1^*, f_1, \ldots, f_n, f_1^*, \ldots, f_1^*\},$$

the adjoint of a $(4n) \times (4n)$-block matrix

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

(A.2.2)

with respect to $b$ is given by

$$\begin{pmatrix} A^* & C^* \\ B^* & D^* \end{pmatrix}.$$

(A.2.3)

Here if $X$ is a $(2n) \times (2n)$-matrix we write $X^*$ for its reflection around the antidiagonal. It follows that in this basis $\mathfrak{h}$ is given by

$$\left\{ \begin{pmatrix} B & A \\ -A^* & C \end{pmatrix} \mid B^* = -B, C^* = -C \right\}.$$

(A.2.4)

**Stable involution** The ordered basis

$$\{e_1, f_1, \ldots, e_n, f_n, e_1^*, \ldots, e_1^*, f_1^*, \ldots, f_1^*\}$$

(A.2.5)

of $W$ determines a maximal torus and root basis of $H$ as in (A.1). Let $\theta$ be the involution of $H$ constructed using the recipe in (A.1) with respect to this root basis. Since $-1$ is contained in the Weyl group of $H$ (as observed in §A.1), $\theta$ is inner. The description of (A.1.3) shows that with respect to the first basis (A.2.1) of $W$, $\theta$ is given by conjugating by the element $s' = \text{diag}(1, \ldots, 1, -1, \ldots, -1)$, where the first $2n$ entries are 1’s and the last $2n$ entries are $-1$’s. Using this description, it is easy to see that

$$\mathfrak{g} := h^\theta = \left\{ \begin{pmatrix} B & 0 \\ 0 & C \end{pmatrix} \mid B^* = -B, C^* = -C \right\},$$

$$\mathfrak{v} := \mathfrak{h}^{\theta = -1} = \left\{ \begin{pmatrix} 0 & A \\ -A^* & 0 \end{pmatrix} \mid A \in \text{Mat}_{2n,2n} \right\}.$$

Moreover $G := (H^\theta)^o$ is isomorphic to $(SO(W_1) \times SO(W_2))/\Delta(\mu_2)$, where $\Delta(\mu_2)$ denotes the image of the diagonal inclusion of $\mu_2$ into the centre $\mu_2 \times \mu_2$ of $SO(W_1) \times SO(W_2)$. Using these identifications, we see that the map

$$\begin{pmatrix} 0 & A \\ -A^* & 0 \end{pmatrix} \mapsto A$$

establishes a bijection between $\mathfrak{v}$ and the representation $\text{Hom}(W_2, W_1)$, where $(g, h) \in SO(W_1) \times SO(W_2)$ acts on $f : W_2 \to W_1$ via $g \circ f \circ h^{-1}$. In terms of matrices, the action is given by $(g, h) \cdot A = gAh^{-1}$. We will typically view an element of $V(\mathbb{Q})$ as a $(2n) \times (2n)$-matrix $A$ or a linear operator $f : W_2 \to W_1$. 65
Roots Let \( T' \) be the maximal torus \( \text{diag}(t_1, \ldots, t_n, t_n^{-1}, \ldots, t_1^{-1}, s_1, \ldots, s_n, s_n^{-1}, \ldots, s_1^{-1}) \) of \( H' \) (again using the basis (A.2.1)), and let \( T \) be its image in \( H \). Then \( T \) is a maximal torus of \( H \) and \( G \); let \( \Phi_H \) and \( \Phi_G \) be the corresponding sets of roots. Let \( W_H = N_H(T)/T \) and \( W_G = N_G(T)/T \) be the respective Weyl groups. The basis (A.2.3) determines a set of positive roots \( \Phi'_G \) of \( H \) (as in §A.1) and by restriction a set of positive roots \( \Phi'_G \) of \( G \). The corresponding simple roots are given by:

\[
S_H = \{t_1 - s_1, s_1 - t_2, \ldots, s_n - t_n, t_n - s_n + s_1\}, \\
S_G = \{t_1 - t_2, \ldots, t_{n-1} - t_n, t_n + t_n - s_n, s_n - s_n + s_1\}.
\]

We label the elements of \( \Phi_H \) using the description of the Weyl group of \( \Omega \) weights of row \( i \). Let \( \Phi \) be the basis (A.2.1)), and let \( T \) be the position of their eigenspaces:

\[
S_H = \{t_1 - s_1, s_1 - t_2, \ldots, s_n - t_n, t_n - s_n + s_1\}, \\
S_G = \{t_1 - t_2, \ldots, t_{n-1} - t_n, t_n + t_n - s_n, s_n - s_n + s_1\}.
\]

We label the elements of \( S_G \) by \( \{\beta_1, \ldots, \beta_n, \gamma_n\} \cup \{\gamma_1, \ldots, \gamma_{n-1}\} \). We have \( \Phi_H = \Phi_G \cup \Phi_V \) and \( \Phi_V = \{\pm t_i \pm s_j \mid 1 \leq i, j \leq n\} \).

Component group Let \( s \) be the image of \( s' \) (defined below (A.2.3) in \( T(\mathbb{Q}) \)). Lemma 3.3 shows that the inclusion \( N_{H^0}(T) \rightarrow H^0 \) induces an isomorphism \( Z_{W_H}(s)/W_G \cong H^0/G \). In fact, let

\[
\Omega = \{w \in W_H \mid w(S_G) = S_G\}. \tag{A.2.6}
\]

Then using the description of the Weyl group of \( H \) and \( G \) from §A.1 we see that \( Z_{W_H}(s) = W_G \times \Omega \) and \( \Omega \cong \mathbb{Z}/2 \times \mathbb{Z}/2 \). Explicit generators of \( \Omega \) are given by \( \omega_1, \omega_2 \), where

\[
\omega_1: t_i \leftrightarrow s_i, \\
\omega_2: \begin{align*}
s_i &\mapsto s_i, t_i &\mapsto t_i, &\quad (1 \leq i \leq n - 1) \\
t_n &\mapsto -t_n, s_n &\mapsto -s_n.
\end{align*}
\]

Weights Using the description of elements of \( V \) as \( (2n) \times (2n) \) matrices, we organise the weights \( \Phi_V \) using the position of their eigenspaces:

\[
\begin{pmatrix}
t_1 - s_1 & \cdots & t_1 - s_n & t_1 + s_n & \cdots & t_1 + s_1 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
-t_n - s_1 & \cdots & -t_n - s_n & -t_n + s_n & \cdots & -t_n + s_1 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
-t_1 - s_1 & \cdots & -t_1 - s_n & -t_1 + s_n & \cdots & -t_1 + s_1
\end{pmatrix} \tag{A.2.7}
\]

The group \( \Omega \) acts on the set of weights \( \Phi_V \) as follows: \( \omega_1 \) flips the elements of \( \Phi_V \) along the antidiagonal of (A.2.7), and \( \omega_2 \) swaps the two middle rows and the two middle columns.

The partial ordering Recall from [S.11] that we have defined a partial ordering on \( X^+(T') \) by declaring that \( a \geq b \) if and only if \( a - b \) has nonnegative coordinates with respect to the basis \( S_G \). Note that this partial ordering is preserved by the action of \( \Omega \) on \( X^+(T') \).

We describe the induced partial ordering on the subset \( \Phi_V \) using the organisation (A.2.7). We first consider the restriction of the partial ordering to the rows and columns of (A.2.7). Let \( 1 \leq i \leq 2n \) and write \( t_i := -t_{2n+1-i}, s_i := -s_{2n+1-i} \) if \( i \geq n + 1 \). The Hasse diagram of the partial ordering restricted to the weights of row \( i \) is given by:

66
(In this diagram, $a \leq b$ if and only if $b$ is to the right of $a$.) The Hasse diagram of column $2n + 1 - i$ is given by swapping the roles of $s_j$ and $t_j$ in the above diagram for every $1 \leq j \leq 2n$. The partial ordering $\Phi_V$ is the one generated by the relations between two elements lying in the same row or column.

For example, $t_1 + s_1$ is the maximal element of $\Phi_V$, and the restriction of the partial ordering to the four $n \times n$ blocks is given by: $a \leq b$ if and only if $b$ is to the top right of $a$.

**Regular nilpotent element** For $\alpha \in \Phi_V$, let $X_\alpha$ be the $(2n) \times (2n)$-matrix with coefficient 1 at the entry corresponding to $\alpha$ using (A.2.7) and zeroes elsewhere. The element $E := \sum_{\alpha \in S_H} X_\alpha$ is a regular nilpotent element of $V(\mathbb{Q})$ and gives rise to an $\mathfrak{sl}_2$-triple $(E, X, F)$ and Kostant section $\kappa = E + \mathfrak{h}(F)$, see §3.6. Since elements of $\mathfrak{h}(F)$ are supported on $\Phi_V \cap \Phi_H^-$ (where $\Phi_H^- = \Phi_H \setminus \Phi_H^+$), every element of $\kappa$ is of the form

$$
\begin{pmatrix}
1 & 0 & \cdots & 0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & 0 & 1 & \cdots & 0 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots
\end{pmatrix}
$$

(A.2.8)

If $\omega \in \Omega$, then $E_\omega := \sum_{\alpha \in \omega(S_H)} X_\alpha$ is again regular nilpotent and gives rise to a Kostant section $\kappa_\omega$. Then $\{\kappa_\omega \mid \omega \in \Omega\}$ is a full set of representatives of $G(\mathbb{Q})$-orbits of Kostant sections.

### A.3 Reducibility conditions

Recall that if $A$ is a $(2n) \times (2n)$-matrix then $A^*$ denotes its reflection along the antidiagonal.

**Proposition A.1.** Let $k/\mathbb{Q}$ be a field and $A \in V(k)$. The following are equivalent:

1. $A$ is a regular semisimple element of $V(k)$;
2. $AA^*$ is a regular semisimple $(2n) \times (2n)$-matrix (in other words, the characteristic polynomial of $AA^*$ has distinct roots in $k^*$);
3. $A^*A$ is a regular semisimple $(2n) \times (2n)$-matrix.

**Proof.** Let $\Delta \in \mathbb{Q}[V]^G$ be the discriminant polynomial of $\mathfrak{h} \simeq \mathfrak{so}_{4n}$ restricted to $V$. Let $D$ be the block matrix $\begin{pmatrix} 0 & A \\ -A^* & 0 \end{pmatrix}$. If $C$ is a square matrix, write $\chi_C \in k[X]$ for its characteristic polynomial. If $f$

67
is a polynomial, write \( \text{disc}(f) \) for its discriminant in the usual sense. The identity (A.1.8) implies that

\[
\text{disc}(\chi_D) = \Delta(A)^2 \cdot \text{Pff}(D)^2.
\]

We have \( \text{Pff}(D) = \pm \det(A) \) since both square to \( \det(D) \), so

\[
\text{disc}(\chi_D) = \Delta(A)^2 \cdot (\det(A))^2 \quad (A.3.1)
\]

On the other hand, if \( f(X) = g(X^2) \) for some polynomial \( g \in k[X] \), then it is elementary to check that

\[
\text{disc}(f) = \pm \text{disc}(g)^2 f(0).
\]

Moreover, by calculating determinants of block matrices we have \( \chi_D(X) = \chi_{-AA^*}(X^2) \). Therefore

\[
\text{disc}(\chi_D) = \pm \text{disc}(\chi_{-AA^*})^2 \cdot (\det(A))^2 \quad (A.3.2)
\]

Both identities (A.3.1) and (A.3.2) hold in \( Q[V][X] \), i.e. they hold when the coefficients of \( A \) are interpreted as variables. Since \( \det \in Q[V] \) is not identically zero, it follows that \( \Delta(A) = \pm \text{disc}(\chi_{-AA^*}) = \pm \text{disc}(\chi_{AA^*}) \).

Since \( \chi_{AA^*} = \chi_{A^*A} \) we also have \( \Delta(A) = \pm \text{disc}(\chi_{A^*A}) \). Since \( A \) is a regular semisimple element of \( V(k) \) if and only if \( \Delta(A) \neq 0 \), the proposition follows.

In the next lemma, we organise the set \( \Phi_V \) using the matrix (A.2.7), and we recall from §A.7 that for a subset \( M \subset \Phi_V \) we have defined \( V(M) \) as the subspace of \( v = \sum_{a \in \Phi_V} v_a \in V \) with the property that \( v_a = 0 \) for all \( a \in M \).

**Corollary A.2.** Suppose that a subset \( M \subset \Phi_V \) satisfies at least one of the following conditions:

1. \( M \) contains a top right \( i \times (2n + 1 - i) \) block for some \( 1 \leq i \leq 2n \);
2. \( M \) contains the top right \( i \times j \) and \( j \times i \) blocks for some \( i, j \geq 1 \) satisfying \( i + j = 2n \).

Then every element of \( V(M)(Q) \) is not regular semisimple.

**Proof.**

1. We may suppose (using the fact that \( A \mapsto A^* \) preserves regular semisimplicity) that \( i \leq n \). Let \( X_1 = \text{span}\{e_1, \ldots, e_n\} \subset W_1 \). Then \( \text{GL}(X_1) \) embeds inside \( \text{SO}(W_1) \), using the map \( g \mapsto \left( \begin{array}{cc} g & 0 \\ 0 & (g^*)^{-1} \end{array} \right) \).

   Suppose that \( A \in V(M)(Q) \). Using the \( \text{GL}(X_1) \)-action to put the top left \( i \times (i - 1) \) block of \( A \) in row echelon form, we may suppose that \( M \) contains the top right \( 1 \times 2n \) block; in other words, we may suppose that \( i = 1 \). In that case, the matrix \( AA^* \) has zeroes on the first row and the last column. This implies that the characteristic polynomial of \( AA^* \) is divisible by \( X^2 \), which implies that \( A \) is not regular semisimple by Proposition (A.1).

2. Assume that \( i \leq j \) and let \( A \in V(M)(Q) \). Then the matrix \( B = AA^* \) is of the form:

\[
\begin{pmatrix}
B_1 & 0 & 0 \\
* & B_2 & 0 \\
* & * & B_3
\end{pmatrix}
\]

Here \( B_1, B_3 \) are \( i \times i \) matrices and \( B_2 \) is a \( (j - i) \times (j - i) \) matrix (it is possible that \( i = j \)). Recall that \( \chi_C \) denotes the characteristic polynomial of a square matrix \( C \). Then we have \( \chi_{AA^*} = \chi_{B_1} \chi_{B_2} \chi_{B_3} \). Since \( B_3 = B_1^\ast \), the polynomial \( \chi_{AA^*} = \chi_{B_1}^2 \chi_{B_2} \) has repeated roots. By Proposition (A.1) this shows that \( A \) is not regular semisimple.

Recall from §A.2 that we may interpret an element \( A \in V(Q) \) as a linear map \( W_2 \to W_1 \). Using the perfect pairings \( b_i \) on \( W_i \) we may thus interpret \( A^* \) as a linear map \( W_1 \to W_2 \), and \( AA^* \) as a linear map \( W_1 \to W_1 \).
Proposition A.3. Let $k/\mathbb{Q}$ be a field and $A \in V(k)$. Assume that there exists an $(n-1)$-dimensional subspace $X \subset W_1$ such that $\text{span}\{X, AA^*(X)\}$ is an $n$-dimensional isotropic subspace of $(W_1, b_1)$. Then $A$ is $k$-reducible.

Proof. If $A$ is not regular semisimple then $A$ is $k$-reducible by definition, so assume that $A$ has invariants $b \in B^\sigma(k)$. (Recall that $B = V \not/ G$.) The Grassmannian of $n$-dimensional isotropic subspaces of $(W_1, b_1)$ has two connected components called rulings of $(W_1, b_1)$, and the subspaces spanned by $\{e_1^*, \ldots, e_n^*\}$ and $\{e_1^*, \ldots, e_{n-1}^*, e_n^*\}$ lie in distinct rulings [Wan18, §2.2]; let $\mathcal{R}$ be the ruling containing the subspace $X_1 := \text{span}\{e_1^*, \ldots, e_n^*\}$. Using the $\Omega$-action we may assume that $\text{span}\{X, AA^*(X)\}$ lies in $\mathcal{R}$. To prove the proposition, it suffices to prove the claim that $G(k)$ acts simply transitively on the set of pairs $(D, Y)$, where $D \in V_\mathbb{C}(k)$ and $Y \subset W_1$ is an $(n-1)$-dimensional subspace such that $\text{span}\{Y, DD^*(Y)\}$ is an $n$-dimensional isotropic subspace of $(W_1, b_1)$ contained in the ruling $\mathcal{R}$. Indeed, the description of the Kostant section $\kappa_b$ from [A.2.8] shows that $(\kappa_b, X_1)$ is such a pair, so the claim implies that $(A, X)$ and $(\kappa_b, X_1)$ are $G(k)$-conjugate. The proof of the claim is identical to the proof of [Sha19, Proposition 4.4] using the results of [Wan18, §2.2.2]; we omit the details. \qed

Corollary A.4. Suppose that $M$ contains the top right $(n-1) \times (n+1)$ and $n \times (n-1)$ blocks. Then every element of $V(M)(\mathbb{Q})$ is $\mathbb{Q}$-reducible.

Proof. If $A \in V(M)(\mathbb{Q})$, a computation shows that the entries of $AA^*$ in the top right $(n-1) \times n$ and $n \times (n-1)$ blocks are zero. In other words, $AA^*$ looks like:

\[
\begin{pmatrix}
* & * & * & 0 & 0 & 0 \\
* & * & * & 0 & 0 & 0 \\
* & * & * & 0 & 0 & 0 \\
* & * & * & * & * & * \\
* & * & * & * & * & * \\
* & * & * & * & * & *
\end{pmatrix}
\]

(A.3.4)

It follows that the subspace $X = \text{span}\{e_{n-1}^*, \ldots, e_1^*\}$ satisfies the assumptions of Proposition [A.3]. \qed

Recall that $C$ denotes the collection of subsets $M$ of $\Phi_V$ with the property that for all $a, b \in \Phi_V$ with $b \in M$ and $a \geq b$ it follows that $a \in M$. Also recall the description of the partial ordering on $\Phi_V$ in §A.2.

Proposition A.5. Let $M \in C$ and suppose that $V(M)(\mathbb{Q})$ contains $\mathbb{Q}$-irreducible elements. Then the following properties hold:

1. $\{t_i - s_i, s_i - t_i\} \subset \Phi_V \setminus M$ for all $1 \leq i \leq n - 1$;
2. $\{t_n - s_n, t_n + s_n, -t_n + s_n, -t_n - s_n\} \subset \Phi_V \setminus M$;
3. for every $1 \leq i \leq n - 2$, either $t_i - s_{i+1}$ or $s_i - t_{i+1}$ lies in $\Phi_V \setminus M$;
4. $\#(\{t_n - s_n, t_{n-1} + s_n, t_n + s_{n-1}, -t_n + s_{n-1}\} \cap M) \leq 2$.

Proof. Note that if $\omega \in \Omega$ then $V(M)(\mathbb{Q})$ contains $\mathbb{Q}$-irreducible elements if and only if $V(\omega(M))(\mathbb{Q})$ does. The first three parts follow from applying Corollary [A.2] to $\omega(M)$ for all $\omega \in \Omega$ and properties of the partial ordering of $\Phi_V$. Part 4 follows from applying Corollary [A.4] to $\omega(M)$ for $\omega \in M$. \qed

The reader is invited to visualise the conditions of Proposition [A.5] using the organisation of the weights $\Phi_V$ of [A.2.7].
A.4 Bounding the remaining cusp integrals

Let $C^{good}$ be the subset of $C$ consisting of those $M \in C$ that satisfy Conditions 1–4 of Proposition A.5. Note that $\omega(M) \in C^{good}$ if $M \in C^{good}$ and $\omega \in \Omega$.

**Lemma A.6.** If $M \in C^{good}$, then every element of $S_G$ is of the form $a_1 + a_2$ for some $a_1, a_2 \in \Phi_V \setminus M$.

**Proof.** Using the $\Omega$-action it suffices to consider $\beta_1, \ldots, \beta_{n-1}$. For $1 \leq i \leq n-2$, we have identities

$$\beta_i = t_i - t_{i+1} = (t_i - s_i) + (s_i - t_{i+1})$$

$$= (t_i - s_{i+1}) + (s_{i+1} - t_{i+1}).$$

At least one of the two boxed terms is in $\Phi_V \setminus M$ by Part 3 of Proposition A.5 and the unboxed terms are always in $\Phi_V \setminus M$ by Part 1 of that proposition. To treat $\beta_{n-1}$, consider the identities

$$\beta_{n-1} = t_{n-1} - t_n = \frac{(t_{n-1} - s_n)}{(t_{n-1} + s_n)} + \frac{(s_n - t_n)}{(-s_n - t_n)}$$

One of the three boxed terms must be contained in $\Phi_V \setminus M$ by Part 4 of Proposition A.5 and all the unboxed terms are contained in $\Phi_V \setminus M$ by Parts 1 and 2 of that proposition.

The discussion in §8.11 and Proposition A.5 show that in order to prove Proposition 8.11 when $H$ is of type $D_{2n}$ for all $n \geq 2$, it suffices to prove the following proposition.

**Proposition A.7.** For every $M \in C^{good}$, there exists a function $f: \Phi_V \setminus M \to \mathbb{R}_{\geq 0}$ with the following properties:

1. $\sum_{a \in \Phi_V \setminus M} f(a) < \#M$;
2. the vector

$$\sum_{\beta \in \Phi_G^+} \beta - \sum_{a \in M} a + \sum_{a \in \Phi_V \setminus M} f(a)a$$ (A.4.1)

has strictly positive coefficients with respect to the basis $S_G$.

We prove Proposition A.7 using induction on $n$. The base case $n = 2$ is easy to check explicitly, and also follows from Case 1 of the proof of Proposition A.8 below (which only assumes $n \geq 2$). See [Tho19] p. 1217 which considers the $D_4$ case in detail and also proves this base case.

To perform the induction step, let $\Phi_{V}^{[1]}$ be the subset of $\Phi_V$ of vectors of the form $\{\pm t_1 \pm s_1\} \cup \{\pm t_1 \pm s_1\}$; in other words, $\Phi_{V}^{[1]}$ consists of the first and last rows and columns of (A.2.7). Similarly let $\Phi_{G}^{[1]}$ for the subset of roots of $\Phi_G$ that have a nonzero coordinate at $\beta_1$ or $\gamma_1$ in the root basis $S_G$. Write $\Phi_V = \Phi_{V}^{[1]} \cup \Phi_{V}^{[n-1]}$ and $\Phi_G = \Phi_{G}^{[1]} \cup \Phi_{G}^{[n-1]}$. Then $\Phi_{V}^{[n-1]}$ and $\Phi_{G}^{[n-1]}$ arise from the constructions of §A.2 with $n$ replaced by $n - 1$. Moreover $\sum_{\beta \in \Phi_{G}^{[1]} \cup \Phi_{G}^{[n-1]}} \beta = (2n - 2)t_1 + (2n - 2)s_1$. To prove Proposition A.7 it therefore suffices to prove the following statement.
Proposition A.8. Let \( n \geq 3 \) be an integer, let \( M \in \mathcal{C}_{\text{good}} \) and write \( M^{[1]} := M \cap \Phi_V^{[1]} \). Then there exists a function \( f^{[1]} : \Phi_V \setminus M \to \mathbb{R}_{\geq 0} \) with the following properties:

1. \( \sum_{a \in \Phi_V \setminus M} f^{[1]}(a) < \#M^{[1]} \);  
2. The vector  
\[
(2n - 2)t_1 + (2n - 2)s_1 - \sum_{a \in M^{[1]}} a + \sum_{a \in \Phi_V \setminus M} f^{[1]}(a)a
\]

has strictly positive coefficients with respect to the basis \( S_G \).

Proof. Note that if the proposition is true for \( M \), it is also true for \( \omega(M) \) for every \( \omega \in \Omega \). We may therefore replace \( M \) by a \( \Omega \)-conjugate in what follows. We also note that it suffices to find for each \( M \in \mathcal{C}_{\text{good}} \) a function \( f^{[1]} : \Phi_V \setminus M \to \mathbb{R}_{\geq 0} \) that satisfies the first property and such that \( (A.4.2) \) has nonnegative (instead of positive) coefficients with respect to \( S_G \). Indeed, by Lemma A.6, every element of \( \beta \in S_G \) is a sum \( a_1 + a_2 \) of two elements of \( \Phi_V \setminus M \) so by adding to \( f^{[1]} \) the function \( a_1 \mapsto \epsilon, a_2 \mapsto \epsilon \) for some very small \( \epsilon \), we may ensure that \( f^{[1]} \) has strictly positive coefficient at every element of \( S_G \).

We will distinguish three cases, after introducing some notation. We say \( M \in \mathcal{C}_{\text{good}} \) is bounded if there exists a function \( f^{[1]} : \Phi_V \setminus M \to \mathbb{R}_{\geq 0} \) satisfying the conclusions of Proposition A.8. If \( M \in \mathcal{C}_{\text{good}} \) we write \( w_1(M) := (2n - 2)t_1 + (2n - 2)s_1 - \sum_{a \in M^{[1]}} a \). Recall that if \( n + 1 \leq i \leq 2n \) then we write \( t_i := -t_{2n+1-i} \) and \( s_i := -s_{2n+1-i} \). We use \( O(\geq 0) \) as a shorthand for an element of \( X^+(T') \) that has nonnegative coordinates with respect to \( S_G \). We also recall the useful formulae \( (A.1.4) \).

Case 1. Suppose that \( M^{[1]} \subset \{ t_1 - s_a, t_1 + s_1, \ldots, t_1 + s_n, -t_n + s_1 \} \). Let \( a \) (respectively \( b \)) be the number of elements of \( M^{[1]} \) contained in the first row (respectively last column). Then \( 1 \leq a, b \leq n + 1 \) and since we may switch the roles of \( t_a \) and \( -t_n \) and similarly for \( \pm s_n \), we may assume that \( M^{[1]} = \{ t_1 + s_a, \ldots, t_1 + s_n, t_b + s_1 \} \). Using the \( \Omega \)-action we may assume that \( a \geq b \). We have

\[
w_1(M) = (2n - 2 - a)t_1 - t_2 - \cdots - t_b
\]
\[
+ (2n - 2 - b)s_1 - s_2 - \cdots - s_a.
\]

If \( a, b \leq n - 1 \), then \( (A.1.4) \) shows that \( w_1(M) \) has positive \( S_G \) coefficients, so \( M \) is evidently bounded. We may therefore assume that \( a = n \) or \( n + 1 \). A computation shows that the coefficients of \( w_1(M) \) at \( \{ \beta_1, \ldots, \beta_{n-1} \} \cup \{ \gamma_1, \ldots, \gamma_{n-1} \} \) are nonnegative (in fact at least \( n+1-a \)), so we focus on the coefficients at \( \beta_{n-1}, \beta_n, \gamma_{n-1}, \gamma_n \). If \( b \leq n - 1 \), then \( w_1(M) = O(\geq 0) + \frac{1}{2}(n-a)(\beta_{n-1} + \beta_n) \). This is negative only when \( a = n + 1 \), so assume that this is the case. Using Lemma A.6 write \( \beta_{n-1} = a_1 + a_2, \beta_n = a_3 + a_4 \) for some \( a_i \in \Phi_V \setminus M \). Choose a function \( f^{[1]} : \Phi_V \setminus M \to \mathbb{R}_{\geq 0} \) such that \( f^{[1]} \) supported on \( \{ a_1, \ldots, a_4 \} \), such that \( \sum_{a \in \Phi_V \setminus M} f^{[1]}(a)a = \frac{1}{2}(\beta_{n-1} + \beta_n) \) and such that \( \sum_{a \in \Phi_V \setminus M} f^{[1]}(a) < \#M^{[1]} \). Such a function exists since \( 2 < \#M^{[1]} \) and shows that \( M \) is bounded in this case.

It remains to treat the case where \( n \leq a, b \leq n + 1 \). A calculation shows that

\[
w_1(M) = \begin{cases} 
O(\geq 0) - \frac{1}{2}\beta_n - \frac{1}{2}\gamma_n & \text{if } (a, b) = (n, n), \\
O(\geq 0) - \beta_n & \text{if } (a, b) = (n + 1, n), \\
O(\geq 0) - \frac{1}{2}(\beta_{n-1} + \beta_n + \gamma_{n-1} + \gamma_n) & \text{if } (a, b) = (n + 1, n + 1).
\end{cases}
\]

In each of these cases, we can use Lemma A.6 to show that \( M \) is bounded.

Case 2. Suppose that \( M^{[1]} \) contains an element of the form \( t_1 - s_a \) with \( 2 \leq a \leq n - 1 \) and is contained in the set \( \{ t_1 - s_a, \ldots, t_1 + s_n, t_n + s_1 \} \). Let \( b \) be the number of elements of \( M^{[1]} \) contained in
Therefore to prove that $M_2$ is bounded, since $2n - a - b < \#M[1] = 2n - a + b$. If $b = n$, (A.4.3) equals $O(\geq 0) - \beta_n$. Therefore Lemma [A.6] and the inequality $(2n - a - b) + 2 < \#M[1]$ show that $M$ is bounded in this case. If $b = n + 1$, (A.4.3) equals $O(\geq 0) - \beta_{n-2} - \beta_{n-1} - \beta_n$. Therefore Lemma [A.6] and the inequality $(2n - a - b) + 6 < \#M[1]$ (which holds since $n \geq 3$) show that $M$ is again bounded in this case.

**Case 3.** Suppose that $M[1]$ is of the form $\{t_1 - s_2, \ldots, t_1 - s_2, t_1 + s_n, \ldots, t_1 + s_n, t_n + s_1, \ldots, t_n + s_1, -t_n + s_1, \ldots, -t_n + s_1\}$ for some $2 \leq a, b \leq n - 1$. Using the $\Omega$-action we may assume that $a \geq b$. A calculation using (A.1.4) shows that
\[
w_1(M) = (a - 3)t_1 - t_2 - \cdots - t_{b-1} + (b-3)s_1 - s_2 - \cdots - s_{a-1}
= (a-3)\beta_1 + \cdots + (a-b-1)\beta_{b-1} + \cdots + (a-b-1)\beta_n - 1/2(a-b-1)(\beta_{b-1} + \beta_n) + (b-3)\gamma_1 + \cdots + (b-a-1)\gamma_{a-1} + \cdots + (b-a-1)\gamma_n - 1/2(b-a-1)(\gamma_{a-1} + \gamma_n).
\]

By assumption $s_1 - t_{b-1} \in \Phi_V \setminus M$ and $a \geq b$, and we compute that
\[
w_1(M) + (a - b)(s_1 - t_{b-1}) = O(\geq 0) - \beta_{b-1} - \cdots - \beta_{n-2} - 1/2(\beta_{b-1} + \beta_n) + O(\geq 0) - \gamma_{a-1} - \cdots - \gamma_{n-2} - 1/2(\gamma_{a-1} + \gamma_n).
\]

Therefore to prove that $M$ is bounded it suffices to prove (using Lemma [A.6]) that
\[
(a - b) + 2((n - b + 1) + (n - a + 1)) < \#M[1] = 4n - a - b + 1.
\]

This inequality is equivalent to $2b > 3$, which is true since $b \geq 2$.

**Conclusion.** Since $M \in C^{\text{good}}$, every $M$ has an $\Omega$-conjugate that falls under one of the above three cases. □
