Abstract: Let \((\xi_i, \mathcal{F}_i)_{i \geq 1}\) be a sequence of martingale differences. Set \(X_n = \sum_{i=1}^{n} \xi_i\) and \(\langle X \rangle_n = \sum_{i=1}^{n} \mathbb{E}(\xi_i^2 | \mathcal{F}_{i-1})\). We prove Cramér’s moderate deviation expansions for \(P(X_n / \sqrt{\langle X \rangle_n} \geq x)\) and \(P(X_n / \sqrt{\mathbb{E}X_n^2} \geq x)\) as \(n \to \infty\). Our results extend the classical Cramér result to the cases of normalized martingales \(X_n / \sqrt{\langle X \rangle_n}\) and standardized martingales \(X_n / \sqrt{\mathbb{E}X_n^2}\), with martingale differences satisfying the conditional Bernstein condition. Applications to elephant random walks and autoregressive processes are also discussed.

Keywords and phrases: Martingales, Cramér’s moderate deviations, Berry-Esseen’s bounds, Elephant random walks.

1. Introduction

Let \((\eta_i)_{i \geq 1}\) be a sequence of independent and identically distributed (i.i.d.) centered real random variables. Denote \(\sigma^2 = \mathbb{E}\eta_1^2\) and \(S_n = \sum_{i=1}^{n} \eta_i\). The well-known central limit theorem (CLT) states that under the Lindeberg condition, it holds

\[
\sup_{x \in \mathbb{R}} \left| P(S_n / (\sigma \sqrt{n}) \leq x) - \Phi(x) \right| \to 0, \quad n \to \infty,
\]

where \(\Phi(x)\) is the standard normal distribution function. The Berry-Esseen bound gives an estimation for the absolute error of the normal approximation: if \(\mathbb{E}|\eta_1|^3 < \infty\), then

\[
\sup_{x \in \mathbb{R}} \left| P(S_n / (\sigma \sqrt{n}) \leq x) - \Phi(x) \right| \leq \frac{c \mathbb{E}|\eta_1|^3}{\sqrt{n} \sigma^3},
\]

where \(c\) is a positive absolute constant. Cramér’s moderate deviation expansion stated below gives an estimation for the relative error of the normal approximation. Cramér [12] proved that if \(\mathbb{E}\exp\{c_0|\eta_1|\} < \infty\) for some constant \(c_0 > 0\), then it holds for all \(0 \leq x = o(\sqrt{n})\),

\[
\ln \frac{P(S_n / (\sigma \sqrt{n}) > x)}{1 - \Phi(x)} = O \left( \frac{1 + x^3}{\sqrt{n}} \right), \quad n \to \infty.
\] (1.1)

In particular, the last equality implies that for all \(0 \leq x = o(n^{1/6})\),

\[
P\left( \frac{S_n / (\sigma \sqrt{n})}{1 - \Phi(x)} > 1 + o(1) \right), \quad n \to \infty.
\] (1.2)

Cramér’s moderate deviations type (1.1) for independent random variables have been well studied. See, for instance, Petrov [32] and Statulevičius [40]. We refer to Chapter VIII of Petrov [33] and Saulis and Statulevičius [1]
Let \((\eta_i, F_i)_{i \geq 1}\) be a sequence of square integrable martingale differences defined on a probability space \((\Omega, \mathcal{F}, P)\). Denote by \(S_n = \sum_{i=1}^{n} \eta_i\), then \((S_n, F_i)_{i \geq 1}\) is a martingale. Assuming that there exist constants \(H, \sigma^2 > 0\) and \(N \geq 0\) such that \(\|\eta_i\|_{\infty} \leq H\) and
\[
\left\| \sum_{i=1}^{n} E(\eta_i^2 | F_{i-1}) - n \sigma^2 \right\|_{\infty} \leq N^2, \tag{1.3}
\]
by the exact convergence rates in martingale CLT of Bolthausen [7], it is known that the term \[\frac{1}{\sqrt{n}} \ln n\] in (1.4) cannot be improved to \[\frac{1}{\sqrt{n}} \ln n\] in (1.4). In Fan, Grama, and Liu [18, 20], the expansions (1.4) and (1.5) have been extended to the case of martingale differences \((\eta_i, F_i)_{i \geq 0}\) satisfying the conditional Bernstein condition
\[
|E(\eta_i^k | F_{i-1})| \leq \frac{1}{2} k! H^{k-2} E(\eta_i^2 | F_{i-1}), \quad \text{for all } k \geq 3 \text{ and } i \geq 1, \tag{1.6}
\]
and condition (1.3). Moreover, the range of validity of (1.5) has been enlarged to \(\sqrt{\ln n} \leq x = o(\sqrt{n})\). Notice that for i.i.d. random variables, Bernstein’s condition (1.6) is equivalent to Cramér’s condition (cf. [18]) and therefore (1.5) implies Cramér’s expansion (1.1).

Recently, under condition (1.3) and assumption that there exists a constant \(\rho \in (0, 1)\) such that
\[
E(|\eta_i|^{2+\rho} | F_{i-1}) \leq H \ E(\eta_i^2 | F_{i-1}), \quad \text{for all } i \geq 1, \tag{1.7}
\]
Fan et al. [19] obtained Cramér’s moderate deviations for self-normalized martingales \(W_n := \frac{S_n}{\sqrt{\sum_{i=1}^{n} \eta_i^2}}\). In particular, they showed that for all \(0 \leq x = o(\eta_i^{\rho/(4\rho+2)})\), it holds
\[
P \left( \frac{W_n > x}{1 - \Phi(x)} \right) = 1 + o(1), \quad n \to \infty. \tag{1.8}
\]

See also Fan et al. [20] for block type self-normalized martingales, where martingales satisfying condition (1.3) are also discussed.

Though Cramér’s moderate deviations for standardized and self-normalized martingales have been established, the counterpart for normalized martingales \(U_n := \frac{S_n}{\sqrt{\sum_{i=1}^{n} E(\eta_i^2 | F_{i-1})}}\) will put a new countenance for the study on the relative errors of the normal approximations. In particular, for i.i.d. random variables, we have \(\sum_{i=1}^{n} E(\eta_i^2 | F_{i-1}) = n \sigma^2\), and normalized martingales become standardized sums \(S_n/(\sigma \sqrt{n})\). The main purpose of this paper is to establish Cramér’s moderate deviations for normalized martingales under (1.6) and the following condition: for all \(x > 0\),
\[
P \left( \left| \frac{1}{n} \sum_{i=1}^{n} E(\eta_i^2 | F_{i-1}) - \sigma^2 \right| \geq x \right) \leq \frac{1}{H} \exp \left\{ -H x^2 n \right\}. \tag{1.9}
\]
Notice that with condition (1.3), it is possible to obtain Cramér’s moderate deviations for normalized martingales via the result of Fan, Grama and Liu [18]. However, condition (1.3) is quite restrictive, and is not satisfied for some natural models, for instance, elephant random walks and autoregressive processes. It is more natural to assume condition (1.9) for the settings mentioned above. Hence, we prefer to establish Cramér’s moderate deviations under condition (1.9) rather than (1.3). From Theorem 2.1 below, it follows that for all $0 \leq x = o(\sqrt{n})$,
\[
\ln \frac{P(U_n > x)}{1 - \Phi(x)} \leq c \left( \frac{x^3}{\sqrt{n}} + \frac{(1 + x) \ln n}{\sqrt{n}} \right). \tag{1.10}
\]
In particular, it implies that for all $0 \leq x = o(n^{1/6})$,
\[
P(U_n > x) \frac{1}{1 - \Phi(x)} = 1 + o(1), \quad n \to \infty. \tag{1.11}
\]
Notice that the range of validity of our expansion (1.11) is same to the one of Cramér’s result (1.2). Moreover, inspecting the proof of Theorem 2.1, we conclude that (1.10) holds true when $U_n$ is replaced by the standardized martingale $S_n/(\sqrt{n} \sigma)$, under the conditions (1.6) and (1.9).

The paper is organized as follows. Our main results are stated and discussed in Section 2. Applications of our results to elephant random walks and autoregressive processes are discussed in Section 3. The remaining sections are devoted to the proofs of theorems.

Throughout the paper, $c$ and $c_\alpha$, probably supplied with some indices, denote respectively a generic positive absolute constant and a generic positive constant depending only on $\alpha$. Their values may vary from line to line.

2. Main results

Let $(\xi_i, F_i)_{i=0,\ldots,n}$ be a finite sequence of martingale differences, defined on a probability space $(\Omega, \mathcal{F}, P)$, where $\xi_0 = 0$, $\{0, \Omega\} = F_0 \subseteq \cdots \subseteq F_n \subseteq \mathcal{F}$ are increasing $\sigma$-fields and $(\xi_i)_{i=1,\ldots,n}$ are allowed to depend on $n$. Set
\[
X_0 = 0, \quad X_k = \sum_{i=1}^{k} \xi_i, \quad k = 1, \ldots, n. \tag{2.1}
\]
Then $(X_i, F_i)_{i=0,\ldots,n}$ is a martingale. Denote by $\langle X \rangle$ the quadratic characteristic of the martingale $X = (X_k, F_k)_{k=0,\ldots,n}$, that is
\[
\langle X \rangle_0 = 0, \quad \langle X \rangle_k = \sum_{i=1}^{k} \mathbb{E}(\xi_i^2 | F_{i-1}), \quad k = 1, \ldots, n. \tag{2.2}
\]
In the sequel we shall use the following conditions:

(A1) There exists a number $\epsilon_n \in (0, \frac{1}{2}]$ such that
\[
|\mathbb{E}(\xi_i^k | F_{i-1})| \leq \frac{1}{2} k! \epsilon_n^{k-2} \mathbb{E}(\xi_i^2 | F_{i-1}), \quad \text{for all } k \geq 2 \text{ and } 1 \leq i \leq n;
\]

(A2) There exist a number $\delta_n \in (0, \frac{1}{2}]$ and a positive constant $C$ such that for all $x > 0$,
\[
P(|\langle X \rangle_n - 1| \geq x) \leq C \exp\{-x^2 \delta_n^{-2}\}.
\]

It is remarked that as $\mathbb{E}\langle X \rangle_n = \sum_{i=1}^{n} \mathbb{E}\xi_i^2$, condition (A2) implies that $(\xi_i, F_i)_{i=0,\ldots,n}$ is standardized, that is, $\sum_{i=1}^{n} \mathbb{E}\xi_i^2$ is close to 1. Clearly, in the case of standardized sums of i.i.d. random variables, with variances $\sigma^2 > 0$ and finite moment generating functions, the conditions (A1) and (A2) are satisfied with $\epsilon_n = O(\frac{1}{\sqrt{n}})$ and $\delta_n = O(\frac{1}{\sqrt{n}})$. In the case of martingales, we assume that $\epsilon_n$ and $\delta_n$ depend on $n$ such that $\epsilon_n, \delta_n \to 0$, $n \to \infty$.

The following theorem gives a Cramér’s moderate deviation expansion for normalized martingales.
Theorem 2.1. Assume that conditions (A1) and (A2) are satisfied. Then for all \(0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})\),
\[
\ln \left| \frac{\text{P}(X_n/\sqrt{\langle X \rangle_n} > x)}{1 - \Phi(x)} \right| \leq c \left( x^3 (\epsilon_n + \delta_n) + (1 + x) (\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right).
\] (2.3)
Moreover, the same inequality holds true when \(X_n/\sqrt{\langle X \rangle_n}\) is replaced by \(-X_n/\sqrt{\langle X \rangle_n}\).

Notice that \(e^x = 1 + O(|x|)\) for all \(|x| = O(1)\). From Theorem 2.1, we have the following result about the equivalence to the normal tail.

Corollary 2.1. Assume that conditions (A1) and (A2) are satisfied. Then for all \(0 \leq x = O(\min\{\epsilon_n^{-1/3}, \delta_n^{-1/3}\})\),
\[
\frac{\text{P}(X_n/\sqrt{\langle X \rangle_n} > x)}{1 - \Phi(x)} = 1 + O \left( x^3 (\epsilon_n + \delta_n) + (1 + x) (\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right).
\] (2.4)
Then for all \(0 \leq x = o(\min\{\epsilon_n^{-1/3}, \delta_n^{-1/3}\})\),
\[
\frac{\text{P}(X_n/\sqrt{\langle X \rangle_n} > x)}{1 - \Phi(x)} = 1 + o(1).
\] (2.5)
Moreover, the same equalities hold true when \(X_n/\sqrt{\langle X \rangle_n}\) is replaced by \(-X_n/\sqrt{\langle X \rangle_n}\).

From Theorem 2.1, by an argument similar to the proof of Corollary 2.2 in Fan et al. [19], we easily obtain the following moderate deviation principle (MDP) result. Such type results for standardized martingales have been established by Gao [23], Worms [42] and Djellout [15]. See also Dedecker et al. [13] and Dedecker et al. [14] for stationary sequences.

Corollary 2.2. Assume that conditions (A1) and (A2) are satisfied. Let \(a_n\) be any sequence of real numbers satisfying \(a_n \to \infty\) and \(a_n \min\{\epsilon_n, \delta_n\} \to 0\) as \(n \to \infty\). Then for each Borel set \(B\),
\[
- \inf_{x \in \overline{B}} \frac{x^2}{2} \leq \liminf_{n \to \infty} \frac{1}{a_n^2} \ln \text{P} \left( \frac{1}{a_n} \frac{X_n}{\sqrt{\langle X \rangle_n}} \in B \right) \leq \limsup_{n \to \infty} \frac{1}{a_n^2} \ln \text{P} \left( \frac{1}{a_n} \frac{X_n}{\sqrt{\langle X \rangle_n}} \in B \right) \leq - \inf_{x \in \overline{B}} \frac{x^2}{2},
\]
where \(B^o\) and \(\overline{B}\) denote the interior and the closure of \(B\), respectively.

The exact Berry-Esseen bounds for standardized martingales under various moment conditions has been established. We refer to Bolthausen [7], Haesler [27], El Machkouri and Ouchti [16], Mourrat [31], [17] and Dedecker et al. [14]. The following theorem gives a Berry-Esseen’s bound for normalized martingales.

Corollary 2.3. Assume that conditions (A1) and (A2) are satisfied. Then it holds
\[
\sup_{x \in \mathbb{R}} \left| \text{P}(X_n/\sqrt{\langle X \rangle_n} \leq x) - \Phi(x) \right| \leq c \left( \delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n| \right).
\] (2.6)

By inspecting the proof of Theorem 2.1, it is easy to see that Theorem 2.1 holds true when \(\text{P}(X_n/\sqrt{\langle X \rangle_n} > x)\) is replaced by \(\text{P}(X_n > x)\).

Theorem 2.2. Assume that conditions (A1) and (A2) are satisfied. Then for all \(0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})\),
\[
\ln \left| \frac{\text{P}(X_n > x)}{1 - \Phi(x)} \right| \leq c_p \left( x^3 (\epsilon_n + \delta_n) + (1 + x) (\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right).
\] (2.7)
With conditions (A1) and \( \| (X)_n - 1 \|_\infty \leq \delta_n^2 \), results similar to (2.7) can be found in Fan et al.\cite{18}. Thus the last theorem can be regarded as an extension of the main result of Fan et al.\cite{18}.

Remark 2.1. From the proof of Theorem 2.1, it is easy to see that Theorems 2.1 and 2.2 hold true when condition (A2) is replaced by the following condition: There exist a number \( \delta_n \in (0, \frac{1}{2}] \) and a constant \( c \) such that for all \( x > 0 \),

\[
P\left( |(X)_n - 1| \geq x \right) \leq c \exp\{-x\delta_n^{-2}\}.
\]

Clearly, when \( 0 < x \leq 1 \), the last condition implies condition (A2).

Remark 2.2. Instead of standardized martingales, we consider the general martingales. Assume that \( \xi_i = \eta_i / (\sqrt{n}\sigma_n) \), where \( (\eta_i, F_i)_{i \geq 1} \) is a sequence of martingale differences satisfying the following three conditions:

(A1') There exist two constants \( A, B > 0 \) such that for all \( n \geq 1 \),

\[
A \leq \sigma_n^2 := \frac{1}{n} \sum_{i=1}^{n} E\eta_i^2 \leq B;
\]

(A2') (Conditional Bernstein's condition) There exists a constant \( H > 0 \) such that for all \( i \geq 1 \),

\[
\left| E(\eta_i^k | F_{i-1}) \right| \leq \frac{1}{2} k! H^{k-2} E(\eta_i^2 | F_{i-1}), \quad k \geq 3;
\]

(A3') There exist two constants \( C_1, C_2 > 0 \) such that for all \( n \) and \( x > 0 \),

\[
P\left( \frac{1}{n\sigma_n^2} \sum_{i=1}^{n} E(\eta_i^2 | F_{i-1}) - 1 \geq x \right) \leq C_1 \exp\left\{ -C_2 x^2 n \right\}.
\]

It is known that if \( (\eta_i)_{i \geq 1} \) are i.i.d. random variables with finite exponential moments, the conditions (A1'), (A2') and (A3') are satisfied; see Proposition 8.2 in \cite{18}. Denote by

\[
U_n = \frac{\sum_{i=1}^{n} \eta_i}{\sqrt{\sum_{i=1}^{n} E(\eta_i^2 | F_{i-1})}}
\]

the normalized martingale. Then, by Theorem 2.1, we have for all \( 0 \leq x = o(\sqrt{n}) \) as \( n \to \infty \),

\[
\ln \frac{P(U_n > x)}{1 - \Phi(x)} \leq c \left( \frac{x^3}{\sqrt{n}} + (1 + x) \ln n \right).
\]

In particular, it implies that for all \( 0 \leq x = o(n^{1/6}) \) as \( n \to \infty \),

\[
P(U_n > x) \cdot \frac{1}{1 - \Phi(x)} = 1 + o(1).
\]

Moreover, by Theorem 2.2, the same results hold true when \( U_n \) is replaced by \( \sum_{i=1}^{n} \eta_i / (\sqrt{n}\sigma_n) \).

3. Applications

3.1. Elephant random walks

The elephant random walk (ERW) is a type of one-dimensional random walk on integers, which has a complete memory of its whole history. It was first introduced in 2004 by Schütz and Trimper \cite{39} in order to study the memory effects in the non-Markovian random walk, and has then raised much interest. The model can be
described as follows. The ERW starts at time $n = 0$, with position $T_0 = 0$. At time $n = 1$, the elephant moves to 1 with probability $1/2$ and to $-1$ with probability $1/2$. So the position of the elephant at time $n = 1$ is given by $T_1 = X_1$, with $X_1$ a Rademacher $\mathcal{R}(q)$ random variable. At time $n$, for $n \geq 2$, an integer $n'$ is chosen from the set $\{1, 2, \ldots, n - 1\}$ uniformly at random. Then $X_n$ is determined stochastically by the following rule:

$$X_n = \begin{cases} X_{n'} & \text{with probability } p \\ -X_{n'} & \text{with probability } 1 - p. \end{cases}$$

In other words, at time $n$, we reinforce $X_{n'}$ with probability $p$ and reduce $X_{n'}$ with probability $1 - p$. Thus, for $n \geq 2$, the position of the elephant at time $n$ is

$$T_n = \sum_{i=1}^{n} X_i,$$

with

$$X_n = \alpha_n X_{\beta_n},$$

where $\alpha_n$ has a Rademacher distribution $\mathcal{R}(p)$, $p \in [0, 1]$, and $\beta_n$ is random with the uniform distribution on the integers $\{1, 2, \ldots, n - 1\}$. Moreover, $\alpha_n$ is independent of $X_1, \ldots, X_n$, and $\beta_1, \beta_2, \ldots$ are independent. Here $p$ is called the memory parameter. The ERW is respectively called diffusive, critical and superdiffusive according to the memory parameter $p \in [0, 3/4)$, $p = 3/4$ and $p \in (3/4, 1]$.

The description of the asymptotic behavior of the ERW has motivated many interesting works. Baur and Bertoin [1] established the functional limit theorem via a method of connection to Pólya-type urns. Coletti, Gava and Schütz [10, 11] derived the CLT and a strong invariance principle for $p \in [0, 3/4]$ and a law of large numbers for $p \in [0, 1]$. Moreover, they also showed that if $p \in (3/4, 1]$, then the ERW converges to a non-degenerate random variable which is not normal. Vázquez Guevara [41] obtained the almost sure CLT. Bercu [4] recovered the CLT via a martingale method. Bercu and Lucile [5] introduced a multi-dimensional ERW, and gave a multivariate CLT. Fan et al. [21] obtained some Cramér’s moderate deviations. Recently, Bertoin [6] studied the memory impacts passages at the origin for ERW in the diffusive regime.

In this subsection, we introduce a generalization of ERW such that the step sizes varying in time. Let $(Z_i)_{i \geq 1}$ be a sequence of positive and i.i.d. random variables, with finite means $\nu = \mathbb{E}[Z_1]$ and variances $\text{Var}(Z_1) = \sigma^2 > 0$. Moreover, $(Z_i)_{i \geq 1}$ is independent of $(X_i)_{i \geq 1}$. An ERW with random step sizes can be described as follows. At time $n = 1$, the elephant moves to $Z_1$ with probability $1/2$ and to $-Z_1$ with probability $1/2$. So the position $Y_1$ of the elephant at time $n = 1$ is given by the following rule:

$$Y_1 = \begin{cases} Z_1 & \text{with probability } 1/2 \\ -Z_1 & \text{with probability } 1/2. \end{cases}$$

For $n \geq 2$, instead of (3.1), the position of the elephant with random step sizes at time $n$ is

$$S_n = \sum_{i=1}^{n} Y_i,$$

where

$$Y_n = \alpha_n X_{\beta_n} Z_n.$$  (3.2)

Notice that $|Y_n| = Z_n$ for all $n \geq 1$. Thus at time $n$, the step size is $Z_n$, which is a random variable. Without loss of generality, we may assume that $\nu = 1$. Otherwise, we may consider the case $S_n/\nu$ instead of $S_n$. Clearly, when $\sigma = 0$, the ERW with random step sizes reduces to the usual ERW.
The next theorem gives some Cramér’s moderate deviations for the ERW with uniformly bounded random step sizes. For \( p \in (0, 3/4) \), denote for all \( n \geq 1 \),

\[
a_n = \frac{\Gamma(n)\Gamma(2p)}{\Gamma(n+2p-1)} \quad \text{and} \quad v_n = \sum_{i=1}^{n} a_i^2.
\]

Notice that the exact values of \( a_n \) and \( v_n \) can be easily calculated via computer.

**Theorem 3.1.** Assume that \( Z_1 \leq C \) and \( p \in (0, 3/4) \). The following inequalities hold.

[i] If \( p \in (0, 1/2] \), then for all \( 0 \leq x = o(\sqrt{n}) \),

\[
\left| \frac{\ln \left( \Pr\left( a_n S_n \geq x \sqrt{v_n (\sigma^2 + 1)} \right) \right)}{1 - \Phi(x)} \right| \leq c_p \frac{x^3}{\sqrt{n}} + (1 + x) \frac{\ln n}{\sqrt{n}}.
\] (3.3)

[ii] If \( p \in (1/2, 3/4) \), then for all \( 0 \leq x = o(n^{(3-4p)/2}) \),

\[
\left| \frac{\ln \left( \Pr\left( a_n S_n \geq x \sqrt{v_n (\sigma^2 + 1)} \right) \right)}{1 - \Phi(x)} \right| \leq c_p \left( \frac{x^3}{n^{(3-4p)/2}} + (1 + x) \frac{\ln n}{n^{(3-4p)/2}} \right).
\] (3.4)

[iii] If \( p = 3/4 \), then for all \( 0 \leq x = o(\sqrt{\ln n}) \),

\[
\left| \frac{\ln \left( \Pr\left( a_n S_n \geq x \sqrt{v_n (\sigma^2 + 1)} \right) \right)}{1 - \Phi(x)} \right| \leq c_p \left( \frac{x^3}{\sqrt{\ln n}} + (1 + x) \frac{\ln \ln n}{\sqrt{\ln n}} \right).
\] (3.5)

Moreover, the same inequalities hold when \( a_n S_n \) is replaced by \(-a_n S_n\). In particular, the inequalities imply that

\[
\Pr\left( a_n S_n \geq x \sqrt{v_n (\sigma^2 + 1)} \right) = 1 + o(1) \quad \text{and} \quad \Pr\left( a_n S_n \leq -x \sqrt{v_n (\sigma^2 + 1)} \right) = 1 + o(1)
\] (3.6)

uniformly for \( 0 \leq x = o(\min\{n^{1/6}, n^{(3-4p)/6}\}) \).

From Theorem 3.1, following an argument similar to the proof of Corollary 2.3, we have the following Berry-Esseen bounds.

**Corollary 3.1.** Assume that \( Z_1 \leq C \) and \( p \in (0, 3/4) \). The following inequalities hold.

[i] If \( p \in (0, 1/2] \),

\[
\sup_{x \in \mathbb{R}} \left| \Pr\left( \frac{a_n S_n}{\sqrt{v_n (\sigma^2 + 1)}} \leq x \right) - \Phi(x) \right| \leq C_p \frac{\ln n}{\sqrt{n}}.
\] (3.7)

[ii] If \( p \in (1/2, 3/4) \),

\[
\sup_{x \in \mathbb{R}} \left| \Pr\left( \frac{a_n S_n}{\sqrt{v_n (\sigma^2 + 1)}} \leq x \right) - \Phi(x) \right| \leq C_p \frac{\ln n}{n^{(3-4p)/2}}.
\] (3.8)

[iii] If \( p = 3/4 \),

\[
\sup_{x \in \mathbb{R}} \left| \Pr\left( \frac{a_n S_n}{\sqrt{v_n (\sigma^2 + 1)}} \leq x \right) - \Phi(x) \right| \leq C \frac{\ln \ln n}{\sqrt{n}}.
\] (3.9)
From the last corollary, we obtain the following CLT for the ERW with uniformly bounded random step sizes: If \( p \in (0, 3/4] \), then
\[
\frac{a_n S_n}{\sqrt{v_n (\sigma^2 + 1)}} \xrightarrow{D} N(0, 1), \quad n \to \infty,
\]
where \( \xrightarrow{D} \) stands for convergence in distribution. For \( p \in (0, 3/4) \), we have
\[
\lim_{n \to \infty} \sqrt{v_n} = 1
\]
(cf. the inequalities (7.1) and (7.2)). Thus, (3.10) also implies that for \( p \in (0, 3/4) \),
\[
\frac{S_n}{\sqrt{(\sigma^2 + 1)n/(3 - 4p)}} \xrightarrow{D} N(0, 1), \quad n \to \infty.
\]
Assume that \( \nu \) and \( \sigma^2 \) are unknown, but the step sizes \( (Z_n)_{n \geq 1} \) are observable. Then we have the following self-normalized type Cramér’s moderate deviations.

**Theorem 3.2.** Theorem 3.1 and Corollary 3.1 remain valid when \( v_n (\sigma^2 + 1) \) is replaced by \( \sum_{i=1}^{n} a_i^2 Z_i^2 \). In particular, for any \( p \in (0, 3/4) \), the following equalities hold
\[
\Pr\left( a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2} \right) = 1 + o(1) \quad \text{and} \quad \Pr\left( a_n S_n \leq -x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2} \right) = 1 + o(1)
\]
uniformly for \( 0 \leq x = o(\min\{n^{1/6}, n^{(3-4p)/6}\}) \).

Self-normalized type Cramér’s moderate deviations is user-friendly since in practice one usually does not know the exact values of \( \nu \) and \( \sigma^2 \).

**Remark 3.1.** If at time \( n = 1 \), the elephant moves to \( Z_1 \) with probability \( q \) and to \( -Z_1 \) with probability \( 1 - q \) for some \( q \in [0, 1] \), then Theorems 3.1 and 3.2 remain valid. The proofs are similar, but \( M_n \) should be redefined as \( a_n S_n - 2q + 1 \) and notice that for all \( 0 \leq x = o(\varepsilon_n^{-1}), \varepsilon_n \searrow 0 \), it holds
\[
1 - \Phi(x + \varepsilon_n) = \left( 1 - \Phi(x) \right) \exp \left\{ \theta c (1 + x) \varepsilon_n \right\},
\]
where \(|\theta| \leq 1\).

### 3.2. Autoregressive processes

The autoregressive processes can be described as follows: for all \( n \geq 0 \),
\[
X_{n+1} = \theta X_n + \varepsilon_{n+1},
\]
where \( \theta, X_n \) and \( \varepsilon_n \) are respectively an unknown parameter, the observations and driven noises. We assume that \( (\varepsilon_n)_{n \geq 0} \) is a sequence of i.i.d. centered random variables with finite variations \( \mathbb{E} \varepsilon_0^2 = \sigma^2 > 0 \) and that \( X_0 = \varepsilon_0 \). The unknown parameter \( \theta \) can be estimated by the following least-squares estimator for all \( n \geq 1 \),
\[
\hat{\theta}_n = \frac{\sum_{k=1}^{n} X_{k-1} X_k}{\sum_{k=1}^{n} X_{k-1}^2}.
\]
When \( (\varepsilon_n)_{n \geq 0} \) are normal random variables, large deviation principles for the case \(|\theta| < 1 \) were established in Bercu et al. [2], and exponential inequalities for the deviation of \( \hat{\theta}_n - \theta \) have been established in Bercu and Touati [3]. See also Jiang et al. [30] for the explosive autoregressive processes. In the following theorem, we give a self-normalized Cramér’s moderate deviation result for \( \hat{\theta}_n - \theta \), provided that the driven noises are bounded.
Theorem 3.3. Assume $|\varepsilon_0| \leq H$ for some positive constant $H$. If $|\theta| < 1$, then for all $0 \leq x = o(\sqrt{n})$,

$$\left| \ln \mathbb{P}\left( \frac{(\hat{\theta}_n - \theta)\sqrt{\sum_{k=1}^{n}X_{k-1}^2}}{1 - \Phi(x)} > x\sigma \right) \right| \leq c \left( \frac{x^3}{\sqrt{n}} + (1 + x)\frac{\ln n}{\sqrt{n}} \right). \quad (3.15)$$

In particular, it implies that for all $0 \leq x = o(n^{1/6})$,

$$\mathbb{P}\left( \frac{(\hat{\theta}_n - \theta)\sqrt{\sum_{k=1}^{n}X_{k-1}^2}}{1 - \Phi(x)} > x\sigma \right) = 1 + o(1), \quad n \to \infty.$$  

Moreover, the results remain valid when $\hat{\theta}_n - \theta$ is replaced by $\theta - \hat{\theta}_n$.

By Theorem 3.3, it is easy to establish the following confidence intervals for the parameter $\theta$.

Corollary 3.2. Assume the condition of Theorem 3.3. Let $\kappa_n \in (0, 1)$. Assume that

$$|\ln \kappa_n| = o(n^{1/3}), \quad n \to \infty.$$  

Then $[A_n, B_n]$, with

$$A_n = \hat{\theta}_n - \frac{\Phi^{-1}(1 - \kappa_n/2)\sigma}{\sqrt{\sum_{k=1}^{n}X_{k-1}^2}} \quad \text{and} \quad B_n = \hat{\theta}_n + \frac{\Phi^{-1}(1 - \kappa_n/2)\sigma}{\sqrt{\sum_{k=1}^{n}X_{k-1}^2}},$$

is a $1 - \kappa_n$ confidence interval for $\theta$, for $n$ large enough.

When the risk probability $\kappa_n$ goes to 0, we still have the following result.

Corollary 3.3. Assume the condition of Theorem 3.3. Let $\kappa_n \in (0, 1)$ such that $k_n \to 0$ and

$$|\ln \kappa_n| = o(n), \quad n \to \infty.$$  

Then $[A_n, B_n]$, with

$$A_n = \hat{\theta}_n - \frac{\sigma \sqrt{2|\ln(\kappa_n/2)|}}{\sqrt{\sum_{k=1}^{n}X_{k-1}^2}} \quad \text{and} \quad B_n = \hat{\theta}_n + \frac{\sigma \sqrt{2|\ln(\kappa_n/2)|}}{\sqrt{\sum_{k=1}^{n}X_{k-1}^2}},$$

is a $1 - \kappa_n$ confidence interval for $\theta$, for $n$ large enough.

Remark 3.2. Following the proof of Theorem 3.3, by Theorem 2.2, we can show that under the conditions of Theorem 3.3, the inequality (3.15) remains valid when $(\hat{\theta}_n - \theta)\sqrt{\sum_{k=1}^{n}X_{k-1}^2}$ is replaced by $(\hat{\theta}_n - \theta)\sqrt{\frac{1 - \theta^2}{\sigma^2}\sum_{k=1}^{n}X_{k-1}^2}$ or $(\theta - \hat{\theta}_n)\sqrt{\frac{1 - \theta^2}{\sigma^2}\sum_{k=1}^{n}X_{k-1}^2}$.

4. Preliminary lemmas

Let $X = (X_k, F_k)_{0 \leq k \leq n}$ be the martingale defined by (2.1). For any real $\lambda$ satisfying $|\lambda| < \varepsilon_n^{-1}$, we follow the method developed by Grama and Haesler [25], and introduce the following exponential multiplicative martingale $Z(\lambda) = (Z_k(\lambda), F_k)_{0 \leq k \leq n}$, where

$$Z_k(\lambda) = \prod_{i=1}^{k} \frac{e^{\lambda \xi_i}}{\mathbb{E}(e^{\lambda \xi_i} | F_{i-1})}, \quad k = 1, \ldots, n, \quad Z_0(\lambda) = 1.$$
Clearly, for each \( k = 1, \ldots, n \), \( Z_k(\lambda) \) defines a probability density on \((\Omega, \mathcal{F}, \mathbb{P})\), i.e.

\[
\int Z_k(\lambda) d\mathbb{P} = \mathbb{E}(Z_k(\lambda)) = 1.
\]

This observation allows us to introduce, for \(|\lambda| < \epsilon_n^{-1}\), the well-known conjugate probability measure \( \mathbb{P}_\lambda \) on \((\Omega, \mathcal{F})\) defined by

\[
d\mathbb{P}_\lambda = Z_n(\lambda)d\mathbb{P}.
\] (4.1)

Denote by \( \mathbb{E}_\lambda \) and \( \mathbb{E} \) the expectations with respect to \( \mathbb{P}_\lambda \) and \( \mathbb{P} \), respectively. For all \( 1 \leq i \leq n \), set

\[
\eta_i(\lambda) = \xi_i - b_i(\lambda) \quad \text{and} \quad b_i(\lambda) = \mathbb{E}_\lambda(\xi_i|\mathcal{F}_{i-1}).
\]

Then we have the following well-known semimartingale decomposition for \( X \):

\[
X_k = Y_k(\lambda) + B_k(\lambda), \quad k = 1, \ldots, n,
\] (4.2)

where

\[
Y_k(\lambda) = \sum_{i=1}^{k} \eta_i(\lambda) \quad \text{and} \quad B_k(\lambda) = \sum_{i=1}^{k} b_i(\lambda)
\] (4.3)

are respectively the conjugate martingale and the drift process with respect to \( \mathbb{P}_\lambda \).

In the proof of Theorem 2.1, we make use of the following three lemmas. The proofs of the lemmas are similar to the corresponding assertions in Fan et al. [18], therefore we omit the proofs.

**Lemma 4.1.** Assume that condition (A1) is satisfied. Then for any constant \( \alpha \in (0, 1) \) and all \( 0 \leq \lambda \leq \alpha \epsilon_n^{-1} \),

\[
(\lambda - c_\alpha \lambda^2 \epsilon_n)(X)_n \leq B_n(\lambda) \leq (\lambda + c_\alpha \lambda^2 \epsilon_n)(X)_n.
\] (4.4)

Next, we introduce the predictable cumulant process \( \Psi(\lambda) = (\Psi_k(\lambda), \mathcal{F}_k)_{k=0,\ldots,n} \), where

\[
\Psi_k(\lambda) = \sum_{i=1}^{k} \mathbb{E}(e^{\lambda \xi_i}|\mathcal{F}_{i-1}).
\] (4.5)

We have the following two-sided bound for the predictable cumulant process \( \Psi(\lambda) \).

**Lemma 4.3.** Assume that condition (A1) is satisfied. Then for any constant \( \alpha \in (0, 1) \) and all \( 0 \leq \lambda \leq \alpha \epsilon_n^{-1} \),

\[
\left| \Psi_n(\lambda) - \frac{\lambda^2}{2}(X)_n \right| \leq c_\alpha \lambda^3 \epsilon_n(X)_n.
\]

We show that \( \mathbb{P}_\lambda \) has the following property.

**Lemma 4.4.** Assume that conditions (A1) and (A2) are satisfied. Then for all \( 0 \leq \lambda = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\}) \), the following two inequalities hold: for all \( 2 \leq k \leq 5 \),

\[
\mathbb{E}_\lambda(|\eta_k(\lambda)|^k|\mathcal{F}_{k-1}) \leq c k!(2\epsilon_n)^{k-2}\mathbb{E}(\xi_i^k|\mathcal{F}_{i-1})
\] (4.6)

and for all \( y \geq 4\lambda \delta_n \),

\[
\mathbb{P}_\lambda \left( |(X)_n - 1| \geq y \right) \leq C \exp \left\{ -y^2 \frac{\delta_n^{-2}}{4} \right\}.
\] (4.7)
Proof. Notice that \( |\eta(\lambda)|^k \leq 2^{k-1}(|\xi|^k + E(\xi||F_{i-1}|^k)), k \geq 2 \). Then for all \( k \geq 2 \) and all \( 0 \leq \lambda = o(\epsilon_n^{-1}) \), we have

\[
E(\lambda |\eta(\lambda)|^k |F_{i-1}) \leq 2^{k-1}E(\xi|^k + E(\xi||F_{i-1}|^k | F_{i-1}) \\
\leq 2^k E(\lambda |\xi|^k |F_{i-1}),
\]

where the last line follows by Jensen’s inequality. Again by Jensen’s inequality, it holds

\[
E(e^{\lambda \xi} |F_{i-1}) \geq e^{\lambda E(\xi ||F_{i-1})} = 1.
\]

By the last inequality, Lemma 4.1 and condition (A1), it follows that for all \( k \geq 2 \) and all \( 0 \leq \lambda = o(\epsilon_n^{-1}) \),

\[
E(\lambda |\eta(\lambda)|^k |F_{i-1}) \leq 2^k \sum_{i=0}^{+\infty} \frac{1}{l!} E(\xi|^l |F_{i-1}) \leq k! (2\epsilon_n)^k \epsilon_n^{k-2} E(\xi^2 |F_{i-1}), \quad (4.8)
\]

which gives the first desired inequality. For all \( 1 \leq k \leq n \), denote \( \Delta \langle Y(\lambda) \rangle_k = E_k (|\eta(\lambda)|^2 |F_{k-1}) \) and \( \Delta \langle X \rangle_k = E_k (\xi_k |F_{k-1}) \). By the definition of conjugate probability measure, it holds for all \( 1 \leq k \leq n \),

\[
\Delta \langle Y(\lambda) \rangle_k = \frac{E(\xi^2 e^{N_k} |F_{k-1})}{E(e^{N_k} |F_{k-1})} - \frac{E(\xi_k e^{N_k} |F_{k-1})^2}{E(e^{N_k} |F_{k-1})^2}.
\] (4.9)

By (4.9) and the inequality \( E(e^{N_k} |F_{k-1}) \geq 1 \), it follows that for all \( 0 \leq \lambda = o(\epsilon_n^{-1}) \),

\[
|\Delta \langle Y(\lambda) \rangle_k - \Delta \langle X \rangle_k| \leq \sum_{l=1}^{\infty} |E(\xi_k^l e^{N_k} |F_{k-1})| \frac{\lambda^l}{l!} + \Delta \langle X \rangle_k \sum_{l=1}^{\infty} |E(\xi_k^l |F_{k-1})| \frac{\lambda^l}{l!} \leq c_0 \lambda \epsilon_n \Delta \langle X \rangle_k. \tag{4.10}
\]

By Lemma 4.3, it is easy to see that for all \( 0 \leq \lambda = o(\epsilon_n^{-1}) \) and all \( y > 0 \),

\[
P_{\lambda} \left(|\langle X \rangle_n - 1| \geq y \right) = E \left(Z_{\lambda} \langle X \rangle_n - 1 | \langle X \rangle_n - 1 | \geq y \right) = E \left(\exp(\lambda X_n - \Psi_n(\lambda))\mathbf{1}(|\langle X \rangle_n - 1| \geq y) \right) \leq E \left(\exp(\lambda X_n - \lambda^2 (X)_n - 4c_\alpha \lambda^3 \epsilon_n(X)_n + \frac{\lambda^2}{2} (X)_n + 5c_\alpha \lambda^3 \epsilon_n(X)_n)\mathbf{1}(|\langle X \rangle_n - 1| \geq y) \right),
\]

where \( c_\alpha \) is given by Lemma 4.3. Using Hölder’s inequality, we get for all \( 0 \leq 2\lambda = o(\epsilon_n^{-1}) \) and all \( y > 0 \),

\[
P_{\lambda} \left(|\langle X \rangle_n - 1| \geq y \right) \leq \left[ E \left(\exp \left(2X_n - \frac{(2\lambda)^2}{2} (X)_n - c_\alpha (2\lambda)^3 \epsilon_n(X)_n \right) \right) \right]^{1/2} \times \left[ E \left(\exp \left(\lambda^2 (X)_n + 10c_\alpha \lambda^3 \epsilon_n(X)_n \right)\mathbf{1}(|\langle X \rangle_n - 1| \geq y) \right) \right]^{1/2}.
\]
By Lemma 4.3 and condition (A2), we get for all $0 \leq \lambda = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$ and all $y \geq 4\lambda \delta_n$,
\[
\mathbb{P}_\lambda \left( |\langle X \rangle_n - 1| \geq y \right) \leq \left[ \mathbb{E} \left( \exp \left\{ \lambda^2 \langle X \rangle_n + 10c_n \lambda^3 \varepsilon_n \langle X \rangle_n \right\} 1_{\{ |\langle X \rangle_n - 1| \geq y \}} \right) \right]^{1/2} \\
\leq e^{\frac{4}{3} \lambda^2} \mathbb{P}(\langle X \rangle_n - 1 < -y) + \mathbb{E} \left( e^{\frac{4}{3} \lambda^2 \langle X \rangle_n} 1_{\{ \langle X \rangle_n \geq 1+y \}} \right)^{1/2} \\
\leq e^{\frac{4}{3} \lambda^2} \mathbb{P}(\langle X \rangle_n - 1 < -y)^{1/2} + e^{\frac{4}{3} \lambda^2 (1+y)} \left[ \mathbb{P}(\langle X \rangle_n - 1 \geq y) \right]^{1/2} \\
+ \frac{4}{3} \lambda^2 \int_{1+y}^{\infty} e^{\frac{4}{3} \lambda^2 t} (t-1)^2 \delta_n^{-2} \, dt^{1/2} \\
\leq C e^{\frac{4}{3} \lambda^2 (1+y)-\frac{3}{2} y^2 \delta_n^{-2}} \\
\leq C \exp \left\{ -\frac{1}{4} y^2 \delta_n^{-2} \right\}.
\] (4.11)

This completes the proof of Lemma 4.4.

In the next lemma, we establish a rate of convergence in the central limit theorem, usually termed as Berry-Esseen’s bound, for the conjugate martingale $P$, with any Berry-Esseen’s bound, for the conjugate martingale $\lambda$.

Lemma 4.5. Assume that conditions (A1) and (A2) are satisfied. Then for all $0 \leq \lambda = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$,
\[
\sup_{x \in \mathbb{R}} \left| \mathbb{P}_\lambda(\langle Y \rangle_n(\lambda) \leq x) - \Phi(x) \right| \leq c \left( \lambda (\varepsilon_n + \delta_n) + \delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n| \right) 
\] (4.12)
and
\[
\sup_{x \in \mathbb{R}} \left| \mathbb{P}_\lambda(\langle Y \rangle_n(\lambda) \leq x, |\langle X \rangle_n - 1| \leq c_0 (\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}) - \Phi(x) \right| \\
\leq c \left( \lambda (\varepsilon_n + \delta_n) + \delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n| \right), 
\] (4.13)
with any $c_0$ large enough.

Grama and Haeusler [25] (cf. Lemma 3.3 therein) obtained a similar bound with the conditions $|\xi_i| \leq \varepsilon_n$ and $\|\langle X \rangle_n - 1\|_\infty \leq \delta_n^2$, which is a particular case of conditions (A1) and (A2). Thus Lemma 4.5 is an extension of Lemma 3.3 in Grama and Haeusler [25].

Proof. Clearly, it holds
\[
\sup_{x \in \mathbb{R}} \left| \mathbb{P}_\lambda(\langle Y \rangle_n(\lambda) \leq x, |\langle X \rangle_n - 1| \leq c_0 (\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}) - \Phi(x) \right| \\
\leq \sup_{x \in \mathbb{R}} \left| \mathbb{P}_\lambda(\langle Y \rangle_n(\lambda) \leq x) - \Phi(x) \right| + \mathbb{P}_\lambda \left( |\langle X \rangle_n - 1| > c_0 (\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}) \right). 
\] (4.14)

By Lemma 4.4, it is easy to see that for all $0 \leq \lambda = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$,
\[
\mathbb{P}_\lambda \left( |\langle X \rangle_n - 1| > c_0 (\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}) \right) \leq c \exp \left\{ -\frac{c_0^2}{4} \delta_n^2 (|\ln \delta_n|)^2 \right\} \\
\leq c \delta_n, 
\] (4.15)
for any $c_0$ large enough. Inequality (4.13) is a simple consequence of (4.12), (4.14) and (4.15). Thus, we only need to prove (4.12). The remaining proof of the lemma is much more complicated and we give details in the supplemental article Fan and Shao [22].
If $\lambda = 0$, then $Y_n(\lambda) = X_n$ and $P_{\lambda} = P$. So Lemma 4.5 implies the following Berry-Esseen bound.

**Theorem 4.1.** Assume that conditions (A1) and (A2) are satisfied. Then the following inequality holds

$$\sup_{x \in \mathbb{R}} |P(X_n \leq x) - \Phi(x)| \leq c_p \left( \epsilon_n |\ln \epsilon_n| + \delta_n |\ln \delta_n| \right).$$

(4.16)

It is known that under the conditions $\|\xi_i\|_\infty \leq \epsilon_n$ and $\|\langle X \rangle_n - 1\|_\infty \leq \delta_n^2$, the best possible convergence rate of Berry-Esseen’s bound for martingales is in order of $\epsilon_n |\ln \epsilon_n| + \delta_n$, see Bolthausen [7] when $\epsilon_n = O(1/\sqrt{n})$ and [17] for general $\epsilon_n$. Thus, the term $\epsilon_n |\ln \epsilon_n|$ is the best possible.

5. Proof of Theorem 2.1

The first assertion of Theorem 2.1 will be deduced by the combination of the following two lemmas (Lemmas 5.1 and 5.2), which are stated and proved respectively in this section. The second assertion of Theorem 2.1 follows from the first one applied to $(-X_i, F_i)_{1 \leq i \leq n}$. The proofs of Lemmas 5.1 and 5.2 are close to the proofs of Theorems 2.1 and 2.2 of Fan et al. [18]. However, Fan et al. [18] considered the standardized martingales $X_n$ with $\|\langle X \rangle_n - 1\|_\infty \leq \delta_n^2$ instead of the normalized martingales $X_n/\sqrt{\langle X \rangle_n}$ with condition (A2).

5.1. Upper bound for normalized martingales

The following lemma gives an upper bound for the relative error of normal approximation.

**Lemma 5.1.** Assume that conditions (A1) and (A2) are satisfied. Then for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\ln \frac{P(X_n > x \sqrt{\langle X \rangle_n})}{1 - \Phi(x)} \leq c \left( x^3 (\epsilon_n + \delta_n) + (1 + x)(\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right),$$

(5.1)

where $c$ does not depend on $(\xi_i, F_i)_{1 \leq i \leq n}$, $n$ and $x$.

**Proof.** For the sake of simplicity of notations, denote

$$\delta_n(\lambda) = c_0(\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}),$$

where $c_0$ is a constant large enough. According to the change of probability measure (4.1), we deduce that for all $0 \leq \lambda = o(\epsilon_n^{-1}),$

$$P \left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda) \right)$$

$$= E_{\lambda} \left( Z_n(\lambda)^{-1} 1_{\{X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda)\}} \right)$$

$$\leq E_{\lambda} \left( e^{-\lambda X_n + \Psi_n(\lambda)} 1_{\{X_n > x \sqrt{1 - \delta_n(\lambda)}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda)\}} \right)$$

$$= E_{\lambda} \left( e^{-\lambda Y_n(\lambda) - \lambda B_n(\lambda) + \Psi_n(\lambda)} 1_{\{Y_n(\lambda) + B_n(\lambda) > x \sqrt{1 - \delta_n(\lambda)}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda)\}} \right)$$

$$\leq E_{\lambda} \left( e^{-\lambda Y_n(\lambda) - \lambda^2 |\epsilon_n| \langle X \rangle_n} 1_{\{Y_n(\lambda) + B_n(\lambda) > x \sqrt{1 - \delta_n(\lambda)}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda)\}} \right),$$

(5.2)

where the last line follows by Lemmas 4.2 and 4.3. Notice that $B_n(\lambda) \leq (\lambda + c_\alpha \lambda^2 |\epsilon_n|) \langle X \rangle_n$ (cf. Lemma 4.2), where $\epsilon_n$ is given by inequality (4.4). For $0 \leq \lambda = o(\epsilon_n^{-1})$, let $\lambda = \lambda(x)$ be the positive solution of the equation

$$\left( \lambda + c_\alpha \lambda^2 |\epsilon_n| \right) \left( 1 + \delta_n(\lambda) \right) = x \sqrt{1 - \delta_n(\lambda)}.$$

(5.3)
The definition of $\bar{\lambda}$ implies that there exist $c_1, c_2 > 0$ such that for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$c_1 x \leq \bar{\lambda} \leq x$$

(5.4)

and

$$\bar{\lambda} = x - c_2 \theta(x) \left( x^2 (\epsilon_n + \delta_n) + x \delta_n \sqrt{\ln \delta_n} \right) \in [0, o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})],$$

(5.5)

where $0 \leq \theta(x) \leq 1$. From (5.2), using equality (5.3), we deduce that for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\mathbb{P} \left( X_n > x \sqrt{(X)_n}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) \leq \exp \left\{ c_3 \left( \bar{\lambda}^3 (\epsilon_n + \delta_n) + \bar{\lambda}^2 \delta_n \sqrt{\ln \delta_n} \right) - \frac{1}{2} \bar{\lambda}^2 \right\} E_X \left( e^{-\bar{\lambda} Y_n(\bar{\lambda})} 1_{\psi_n(\bar{\lambda}) > 0}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right)$$

(5.6)

Clearly, it holds for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$E_X \left( e^{-\bar{\lambda} Y_n(\bar{\lambda})} 1_{\psi_n(\bar{\lambda}) > 0}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) = \int_0^{\infty} \bar{\lambda} e^{-\bar{\lambda} y} \mathbb{P}_X \left( Y_n(\bar{\lambda}) \leq y, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) dy.$$

(5.7)

Similarly, for a standard normal random variable $\mathcal{N}$, it holds

$$\mathbb{E} \left( e^{-\bar{\lambda} \mathcal{N}} 1_{\mathcal{N} > 0} \right) = \int_0^{\infty} \bar{\lambda} e^{-\bar{\lambda} y} \mathbb{P}(0 < \mathcal{N} \leq y) dy.$$

(5.8)

From (5.7) and (5.8), it follows that for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\left| E_X \left( e^{-\bar{\lambda} Y_n(\bar{\lambda})} 1_{\psi_n(\bar{\lambda}) > 0}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) - \mathbb{E} \left( e^{-\bar{\lambda} \mathcal{N}} 1_{\mathcal{N} > 0} \right) \right| \leq 2 \sup_y \left| P_X (Y_n(\bar{\lambda}) \leq y, |(X)_n - 1| \leq \delta_n(\bar{\lambda})) - \Phi(y) \right|.$$

Using Lemma 4.5, we have the following bound for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\left| E_X \left( e^{-\bar{\lambda} Y_n(\bar{\lambda})} 1_{\psi_n(\bar{\lambda}) > 0}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) - \mathbb{E} \left( e^{-\bar{\lambda} \mathcal{N}} 1_{\mathcal{N} > 0} \right) \right| \leq c_3 \left( \bar{\lambda} (\epsilon_n + \delta_n) + \delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n| \right).$$

(5.9)

Combining (5.6) and (5.9) together, we get for all $0 \leq x = o(\min \{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\mathbb{P} \left( X_n > x \sqrt{(X)_n}, |(X)_n - 1| \leq \delta_n(\bar{\lambda}) \right) \leq \exp \left\{ c_4 \left( \bar{\lambda}^3 (\epsilon_n + \delta_n) + \bar{\lambda}^2 \delta_n \sqrt{\ln \delta_n} \right) - \frac{1}{2} \bar{\lambda}^2 \right\} \times \left( \mathbb{E} \left( e^{-\bar{\lambda} \mathcal{N}} 1_{\mathcal{N} > 0} \right) \right).$$

(5.10)

Since

$$e^{-\lambda^2/2} \mathbb{E} \left( e^{-\lambda \mathcal{N}} 1_{\mathcal{N} > 0} \right) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} e^{-(y+\lambda)^2/2} dy = 1 - \Phi(\lambda)$$

(5.11)

and

$$\frac{1}{\sqrt{\pi(1+\lambda)}} e^{-\lambda^2/2} \geq 1 - \Phi(\lambda) \geq \frac{1}{\sqrt{2\pi(1+\lambda)}} e^{-\lambda^2/2}, \quad \lambda \geq 0$$

(5.12)
(see [25]), we deduce that for all \(0 \leq x = o(\min\{e_n^{-1}, \delta_n^{-1}\})\),
\[
\frac{P\left(X_n > x\sqrt{|\langle X \rangle_n|}, |\langle X \rangle_n| - 1 \leq \delta(\bar{X})\right)}{1 - \Phi(\bar{X})} \leq \exp \left\{ c_4 \left( X^2(\epsilon_n + \delta_n) + \bar{X}^2\delta_n\sqrt{\ln \delta_n}\right) \right\} \\
\times \left( 1 + c_5 (1 + \bar{X})\left( \bar{X}(\epsilon_n + \delta_n) + |\delta_n| + \epsilon_n|\ln \epsilon_n|\right) \right) .
\] (5.13)

Next, we would like to compare \(1 - \Phi(\bar{X})\) with \(1 - \Phi(x)\). By (5.4), (5.5) and (5.12), we deduce that for all \(0 \leq x = o(\min\{e_n^{-1}, \delta_n^{-1}\})\),
\[
1 \geq \frac{\int_{-\infty}^{\infty} \exp\left(-t^2/2\right) \exp\left(-t^2/2\right) dt}{\int_{-\infty}^{\infty} \exp\left(-t^2/2\right) dt} \geq 1 + c_1 (1 + x)(x - \bar{X})\exp\left(\frac{1}{2}(x^2 - \bar{X}^2)\right) \\
\geq \exp \left\{ c_2 (1 + x)\left( x^2(\epsilon_n + \delta_n) + x\delta_n\sqrt{\ln \delta_n}\right) \right\} .
\] (5.14)

So, it holds for all \(0 \leq x = o(\min\{e_n^{-1}, \delta_n^{-1}\})\),
\[
1 - \Phi(\bar{X}) = \left( 1 - \Phi(x)\right) \exp \left\{ \theta_1 c_6 (1 + x)\left( x^2(\epsilon_n + \delta_n) + x\delta_n\sqrt{\ln \delta_n}\right) \right\} ,
\] (5.15)
where \(0 \leq \theta_1 \leq 1\). Implementing (5.15) in (5.13), by (5.4), we obtain for all \(0 \leq x = o(\min\{e_n^{-1}, \delta_n^{-1}\})\),
\[
\frac{P\left(X_n > x\sqrt{|\langle X \rangle_n|}, |\langle X \rangle_n| - 1 \leq \delta(\bar{X})\right)}{1 - \Phi(\bar{X})} \leq \exp \left\{ c_7 \left( (1 + x)x^2(\epsilon_n + \delta_n) + (1 + x + x^2)\delta_n\sqrt{\ln \delta_n}\right) \right\} \\
\times \left( 1 + c_5 (1 + x)(x(\epsilon_n + \delta_n) + \delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right) \\
\leq \exp \left\{ c_8 \left( x^3(\epsilon_n + \delta_n) + (x + x^2)\delta_n\sqrt{\ln \delta_n} + (1 + x)(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right) \right\} ,
\] where the last line follow by the inequality \(1 + x \leq e^x\) for all \(x \geq 0\). Clearly, for all \(0 \leq x \leq \sqrt{\ln \delta_n}\),
\[
(x + x^2)\delta_n\sqrt{\ln \delta_n} + (1 + x)x(\epsilon_n + \delta_n) \leq (1 + x)(\delta_n|\ln \delta_n| + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)(\ln 2)^{-1} \leq 3(1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)
\]
and for all \(x > \sqrt{\ln \delta_n}\),
\[
(x + x^2)\delta_n\sqrt{\ln \delta_n} + (1 + x)x(\epsilon_n + \delta_n) \leq 2x^3\delta_n + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)(\ln 2)^{-1} \leq 2\left( x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right) .
\]
Thus for all \(0 \leq x = o(\min\{e_n^{-1}, \delta_n^{-1}\})\),
\[
\frac{P\left(X_n > x\sqrt{|\langle X \rangle_n|}, |\langle X \rangle_n| - 1 \leq \delta(\bar{X})\right)}{1 - \Phi(\bar{X})} \leq \exp \left\{ c_9 \left( x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right) \right\} .
\]
By condition (A2), we have for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$, 
\[ P\left( |\langle X \rangle_n - 1| > \delta_n(\lambda) \right) \leq C \exp\left\{ - (\delta_n(\lambda))^2 \delta_n^{-2} \right\}. \]
Taking $c_0$ large enough, by (5.12), we deduce that for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$, 
\[ \frac{P\left( |\langle X \rangle_n - 1| > \delta_n(\lambda) \right)}{1 - \Phi(x)} \leq c(1 + x) \exp\left\{ \frac{x^2}{2} - (\delta_n(\lambda))^2 \delta_n^{-2} \right\} \leq \delta_n. \]
Notice that 
\[ P\left( X_n > x \sqrt{\langle X \rangle_n} \right) \leq P\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda) \right) + P\left( |\langle X \rangle_n - 1| > \delta_n(\lambda) \right). \]
Hence, we get for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$, 
\[ \frac{P\left( X_n > x \sqrt{\langle X \rangle_n} \right)}{1 - \Phi(x)} \leq \frac{P\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda) \right)}{1 - \Phi(x)} + \frac{P\left( |\langle X \rangle_n - 1| > \delta_n(\lambda) \right)}{1 - \Phi(x)} \]
\[ \leq \exp\left\{ c_1 \left( x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|) \right) \right\} + \delta_n \]
\[ \leq \exp\left\{ c_2 \left( x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|) \right) \right\}, \]
which implies the desired inequality. This completes the proof of Lemma 5.1. \hfill \square

5.2. Lower bound for normalized martingales

The next lemma gives a lower bound for the relative error of normal approximation.

**Lemma 5.2.** Assume that conditions (A1) and (A2) are satisfied. Then for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$, 
\[ \ln \frac{P\left( X_n > x \sqrt{\langle X \rangle_n} \right)}{1 - \Phi(x)} \geq -c \left( x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|) \right), \tag{5.16} \]
where $c$ does not depend on $(\xi_i, F_i)_{i=0,\ldots,n}$, $n$ and $x$.

**Proof.** Recall 
\[ \delta_n(\lambda) = c_0(\lambda \delta_n + \delta_n \sqrt{|\ln \delta_n|}), \]
where $c_0$ is positive constant large enough. By an argument similar to (5.2), we have for all $0 \leq \lambda = o(\epsilon_n^{-1})$, 
\[ P\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda) \right) \]
\[ \geq E_{\lambda} \left( e^{-\lambda X_n(\lambda)} - \frac{\lambda^2}{2} X_n(\lambda) - c_0 \lambda^3 \epsilon_n(\lambda) \right) \mathbb{1}_{\{Y_n(\lambda) + B_n(\lambda) > x \sqrt{1 + \delta_n(\lambda)}, |\langle X \rangle_n - 1| \leq \delta_n(\lambda)\}}. \tag{5.17} \]
Notice that $B_n(\lambda) \leq (\lambda - c_\alpha \lambda^2 \epsilon_n)\langle X \rangle_n$ (cf. Lemma 4.2), where $c_\alpha$ is given by inequality (4.4). Let $\Delta = \Delta(x)$ be the smallest solution of the equation 
\[ \left( \lambda - c_\alpha \lambda^2 \epsilon_n \right) \left( 1 - \delta_n(\lambda) \right) = x \sqrt{1 + \delta_n(\lambda)}. \tag{5.18} \]
The definition of $\Delta$ implies that for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$x \leq \Delta \leq c_1 x$$

(5.19)

and

$$\Delta = x - c_2 \theta(x) \left( x^2 (\epsilon_n + \delta_n) + x \delta_n \sqrt{\ln \delta_n} \right) \in \left[0, o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})\right],$$

(5.20)

where $0 \leq \theta(x) \leq 1$. From (5.17), using Lemmas 4.2, 4.3 and equality (5.18), we get for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$,

$$\mathbb{P}\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq \exp \left\{ - c_4 \left( \Delta^2 (\epsilon_n + \delta_n) + \Delta^2 \delta_n - \frac{1}{2} \Delta^2 \right) \right\} \times \mathbb{E}_\Delta \left( e^{-\lambda_n(\Delta)} 1_{\{Y_n(\Delta) > 0, |\langle X \rangle_n - 1| \leq \delta_n(\Delta)\}} \right).$$

(5.21)

We distinguish two cases to estimate the right hand side of the last inequality.

First, we consider the case $0 \leq \Delta \leq \alpha_1 \min\{\epsilon_n^{-1/2}, \delta_n^{-1/2}\}$, where $\alpha_1 > 0$ is a small constant whose exact value will be given later. The argument for the proof of inequality (5.10) holds also when $X$ is replaced by $\Delta$, thus we have

$$\mathbb{P}\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq \exp \left\{ - c_4 \left( \Delta^2 (\epsilon_n + \delta_n) + \Delta^2 \delta_n - \ln \delta_n \right) \right\} \times \left( 1 - c_4 (1 + \Delta) \left( \Delta (\epsilon_n + \delta_n) + \delta_n \ln \delta_n + \epsilon_n \ln \epsilon_n \right) \right).$$

Using the inequalities (5.11) and (5.12), we obtain the following lower bound on tail probabilities:

$$\mathbb{P}\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq \exp \left\{ - c_5 (1 + \Delta) \left( \Delta (\epsilon_n + \delta_n) + \delta_n \ln \delta_n + \epsilon_n \ln \epsilon_n \right) \right\}. $$

(5.22)

Taking $\alpha_1 = (4c_4)^{-1/2}$, we deduce that for all $0 \leq \Delta \leq \alpha_1 \min\{\epsilon_n^{-1/2}, \delta_n^{-1/2}\}$,

$$1 - c_4 (1 + \Delta) \left( \Delta (\epsilon_n + \delta_n) + \delta_n \ln \delta_n + \epsilon_n \ln \epsilon_n \right) \geq \exp \left\{ - c_5 (1 + \Delta) \left( \Delta (\epsilon_n + \delta_n) + \delta_n \ln \delta_n + \epsilon_n \ln \epsilon_n \right) \right\}. $$

(5.23)

Implementing (5.23) in (5.22), we obtain for all $0 \leq \Delta \leq \alpha_1 \min\{\epsilon_n^{-1/2}, \delta_n^{-1/2}\}$,

$$\mathbb{P}\left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq \exp \left\{ - c_7 \left( \Delta^2 (\epsilon_n + \delta_n) + (1 + \Delta) \left( \Delta (\epsilon_n + \delta_n) + \delta_n \ln \delta_n + \epsilon_n \ln \epsilon_n \right) \right) \right\}.$$

(5.24)

Next, we consider the case $\alpha_2 \min\{\epsilon_n^{-1/2}, \delta_n^{-1/2}\} \leq \Delta = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\}).$ Let $K \geq 1$ be a constant depending on $\alpha_1$, whose exact value will be chosen later. Clearly, we have

$$\mathbb{E}_\Delta \left( e^{-\lambda_n(\Delta)} 1_{\{Y_n(\Delta) > 0, |\langle X \rangle_n - 1| \leq \delta_n(\Delta)\}} \right) \geq \mathbb{E}_\Delta \left( e^{-\lambda_n(\Delta)} 1_{\{0 < Y_n(\Delta) \leq K \gamma_n, |\langle X \rangle_n - 1| \leq \delta_n(\Delta)\}} \right) \geq e^{-\Delta N} \mathbb{P}_\Delta \left( 0 < Y_n(\Delta) \leq K \gamma_n, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right).$$

(5.25)
where $\gamma_n = \lambda (\varepsilon_n + \delta_n) + \delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n|$. Using Lemmas 4.4 and 4.5, we deduce that for all $1 \leq \Delta = o(\min\{\varepsilon_n, \delta_n^{-1}\})$, 

$$P_\Delta \left( 0 < Y_\Delta \leq K \gamma_n, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq P \left( 0 < \mathcal{N} \leq K \gamma_n \right) - \epsilon_1 \gamma_n - \frac{1}{\sqrt{2\pi}} K \gamma_n e^{-K^2 \gamma_n^2/2} - \epsilon_2 \gamma_n$$

$$\geq \left( \frac{1}{4} K - c_3 \right) \gamma_n.$$

Letting $K \geq 8 c_1$, it follows that 

$$P_\Delta \left( 0 < Y_\Delta \leq K \gamma_n, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq \frac{1}{\sqrt{\pi (1 + \Delta)}}.$$

Since the inequality $\frac{1}{\sqrt{\pi (1 + \Delta)}} e^{-\lambda^2/2} \geq 1 - \Phi(\lambda)$ is valid for all $\lambda \geq 0$ (see (5.12)), it follows that for all $\alpha_1 \min\{\varepsilon_n^{-1/2}, \delta_n^{-1/2}\} \leq \Delta = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$, 

$$P_\Delta \left( 0 < Y_\Delta \leq K \gamma_n, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \geq (1 - \Phi(\Delta)) \epsilon_1^3/2.$$

From (5.21), using the inequalities (5.25) and (5.26), we obtain for all $\alpha_1 \min\{\varepsilon_n^{-1/2}, \delta_n^{-1/2}\} \leq \Delta = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$, 

$$P \left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \frac{1 - \Phi(\Delta)}{1 - \Phi(x)} \geq \exp \left\{ - c_8 \left( \lambda^3 (\varepsilon_n + \delta_n) + \lambda^2 \delta_n \sqrt{|\ln \delta_n| + \lambda (\delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n|)} \right) \right\}.$$

Putting (5.24) and (5.27) together, we obtain for all $0 \leq \Delta = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$, 

$$P \left( X_n > x \sqrt{\langle X \rangle_n}, |\langle X \rangle_n - 1| \leq \delta_n(\Delta) \right) \frac{1 - \Phi(\Delta)}{1 - \Phi(x)} \geq \exp \left\{ - c_9 \left( \lambda^3 (\varepsilon_n + \delta_n) + \lambda^2 \delta_n \sqrt{|\ln \delta_n| + (1 + \Delta) (\delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n|)} \right) \right\} \geq \exp \left\{ - c_{10} \left( \lambda^3 (\varepsilon_n + \delta_n) + (1 + \Delta) (\delta_n |\ln \delta_n| + \varepsilon_n |\ln \varepsilon_n|) \right) \right\}.$$

where the last line follows by the inequality for all $\Delta \geq 0$, 

$$\lambda^2 \delta_n \sqrt{|\ln \delta_n|} \leq \lambda^3 \delta_n + \lambda \delta_n |\ln \delta_n|.$$ 

As in the proof of Lemma 5.1, we now compare $1 - \Phi(\Delta)$ with $1 - \Phi(x)$. Similar to (5.15), we have for all $0 \leq x = o(\min\{\varepsilon_n^{-1}, \delta_n^{-1}\})$, 

$$1 - \Phi(\Delta) = \left( 1 - \Phi(x) \right) \exp \left\{ - \theta(x) c_1 (1 + x) (x^2 (\varepsilon_n + \delta_n) + x \delta_n \sqrt{|\ln \delta_n|}) \right\}.$$
where $0 \leq \theta(x) \leq 1$. From (5.28), using (5.19) and (5.29), we get for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$,

\[
\frac{P\left(X_n > x\sqrt{\langle X_n \rangle}_n, |\langle X_n \rangle_n - 1| \leq \delta_n(\lambda)\right)}{1 - \Phi(x)} \geq \exp\left\{-c_2 \left((1 + x)x^2(\epsilon_n + \delta_n) + (x + x^2)\delta_n \sqrt{\ln \delta_n} + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right)\right\}
\]

\[
\geq \exp\left\{-c_3 \left(x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right)\right\}.
\]

Hence, we have for all $0 \leq x = o(\min\{\epsilon_n^{-1}, \delta_n^{-1}\})$,

\[
\frac{P(X_n > x\sqrt{\langle X_n \rangle}_n, |\langle X_n \rangle_n - 1| \leq \delta_n(\lambda))}{1 - \Phi(x)} \geq \exp\left\{-c_4 \left(x^3(\epsilon_n + \delta_n) + (1 + x)(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)\right)\right\}.
\]

This completes the proof of Lemma 5.2. \hfill \square

6. Proof of Corollary 2.3

Denote $\gamma_n = (\epsilon_n + \delta_n)^{1/8}$. Clearly, it holds

\[
\sup_{x \in \mathbb{R}} \left|P(X_n/\sqrt{\langle X \rangle)_n} \leq x\right) - \Phi(x)\right| \leq \sup_{x > \gamma_n^{1/8}} \left|P(X_n/\sqrt{\langle X \rangle)_n} \leq x\right) - \Phi(x)\right| + \sup_{0 \leq x \leq \gamma_n^{-1/8}} \left|P(X_n/\sqrt{\langle X \rangle)_n} \leq x\right) - \Phi(x)\right|
\]

\[
\quad + \sup_{-\gamma_n^{-1/8} \leq x \leq 0} \left|P(X_n/\sqrt{\langle X \rangle)_n} \leq x\right) - \Phi(x)\right| + \sup_{x < -\gamma_n^{-1/8}} \left|P(X_n/\sqrt{\langle X \rangle)_n} \leq x\right) - \Phi(x)\right|
\]

\[
= H_1 + H_2 + H_3 + H_4.
\]

By Theorem 2.1, we deduce that

\[
H_1 = \sup_{x > \gamma_n^{1/8}} \left|P(X_n/\sqrt{\langle X \rangle)_n} > x\right) - (1 - \Phi(x))\right|
\]

\[
\leq \sup_{x > \gamma_n^{1/8}} P(X_n/\sqrt{\langle X \rangle)_n} > x) + \sup_{x > \gamma_n^{1/8}} (1 - \Phi(x))
\]

\[
\leq P(X_n/\sqrt{\langle X \rangle)_n} > \gamma_n^{-1/8}) + (1 - \Phi(\gamma_n^{-1/8}))
\]

\[
\leq (1 - \Phi(\gamma_n^{-1/8}))e^c + \exp\{-\frac{1}{2}\gamma_n^{-1/4}\}
\]

\[
\leq c_1(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|)
\]

and

\[
H_4 \leq \sup_{x < -\gamma_n^{-1/8}} P(X_n/\sqrt{\langle X \rangle)_n} \leq x) + \sup_{x < -\gamma_n^{-1/8}} \Phi(x)
\]

\[
\leq P(X_n/\sqrt{\langle X \rangle)_n} \leq -\gamma_n^{-1/8}) + \Phi(-\gamma_n^{-1/8})
\]

\[
\leq \Phi(-\gamma_n^{-1/8})e^c + \exp\{-\frac{1}{2}\gamma_n^{-1/4}\}
\]

\[
\leq c_2(\delta_n|\ln \delta_n| + \epsilon_n|\ln \epsilon_n|).
\]
By Theorem 2.1 and the inequality \( |e^x - 1| \leq |x|e^{|x|} \), we get

\[
H_2 = \sup_{0 \leq x \leq \gamma_n^{-1/8}} |P\left( \frac{X_n}{\sqrt{\langle X \rangle_n}} > x \right) - \left( 1 - \Phi(x) \right)|
\]

\[
\leq \sup_{0 \leq x \leq \gamma_n^{-1/8}} c_1 \left( 1 - \Phi(x) \right) \left( x^3 (\epsilon_n + \delta_n) + (1 + x) (\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right)
\]

\[
\leq c_3 \left( \delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n| \right)
\]

and

\[
H_3 = \sup_{-\gamma_n^{-1/8} \leq x \leq 0} |P\left( \frac{X_n}{\sqrt{\langle X \rangle_n}} \leq x \right) - \Phi(x)|
\]

\[
\leq \sup_{-\gamma_n^{-1/8} \leq x \leq 0} c_1 \Phi(x) \left( x^3 (\epsilon_n + \delta_n) + (1 + x) (\delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n|) \right)
\]

\[
\leq c_4 \left( \delta_n |\ln \delta_n| + \epsilon_n |\ln \epsilon_n| \right).
\]

Applying the upper bounds of \( H_1, H_2, H_3 \) and \( H_4 \) to (6.1), we obtain the desired inequality. This completes the proof of Corollary 2.3.

7. Proofs of Theorems 3.1 and 3.2

7.1. Some lemmas

By the well-known Stirling’s formula

\[
\ln \Gamma(x) = (x - \frac{1}{2}) \ln x - x + \frac{1}{2} \ln 2\pi + O\left( \frac{1}{x} \right) \quad \text{as} \quad x \to \infty,
\]

we deduce that

\[
\lim_{n \to \infty} a_n n^{2p-1} = \Gamma(2p). \quad (7.1)
\]

Moreover, for \( p \in (0, 3/4) \), we have

\[
\lim_{n \to \infty} \frac{v_n}{n^{3-4p}} = \frac{\Gamma(2p)^2}{3 - 4p}. \quad (7.2)
\]

and, for \( p = 3/4 \), it holds

\[
\lim_{n \to \infty} \frac{v_n}{\ln n} = \frac{\pi}{4}. \quad (7.3)
\]

See also Bercu [4] for the equalities (7.1)-(7.3). Denote

\[
\gamma_n = 1 + \frac{2p - 1}{n}, \quad n \geq 1.
\]

It is easy to see that for all \( n \geq 2 \),

\[
a_n = \prod_{i=1}^{n-1} \frac{1}{\gamma_i}.
\]
Define the filtration $\mathcal{F}_n = \sigma\{Y_i : 1 \leq i \leq n\}$ and
\[
M_n = a_n S_n. \tag{7.4}
\]
Then $(M_n, \mathcal{F}_n)_{n \geq 1}$ is a martingale. Indeed, for all $n \geq 0$, it is easy to verify that
\[
\mathbb{E}[M_{n+1}|\mathcal{F}_n] = \mathbb{E}[a_{n+1}(S_n + a_n X_{\beta_n} Z_n)|\mathcal{F}_n] = a_{n+1} S_n + a_{n+1} \mathbb{E}[\alpha_n |\mathcal{F}_n] \mathbb{E}[X_{\beta_n} |\mathcal{F}_n] \mathbb{E}[Z_n] = a_{n+1} S_n + (2p - 1) \frac{S_n}{n} = a_n S_n = M_n \quad \text{a.s.} \tag{7.5}
\]
Moreover, the martingale $(M_n)_{n \geq 1}$ can be rewritten in the following additive form
\[
M_n = \sum_{i=1}^{n} a_i \varepsilon_i, \tag{7.6}
\]
where $\varepsilon_i = S_i - \gamma_i - S_{i-1} \text{ with } S_0 = 0$. Set $(\Delta M_n)_{n \geq 1}$ be the martingale differences defined by $\Delta M_1 = M_1$ and for all $n \geq 2$,
\[
\Delta M_n = M_n - M_{n-1}.
\]
In the proof of Theorem 3.1, we need the following lemma for the boundness of martingale differences.

Lemma 7.1. Assume that $Z_1 \leq C$. For all $n \geq 1$ and $p \in [0, 1]$, it holds
\[
\|\Delta M_n\|_\infty \leq 2C a_n.
\]

Proof. It holds obviously that for $n = 1$,
\[
\|\Delta M_1\|_\infty = \|S_1\|_\infty \leq 2C.
\]
Observe that for all $n \geq 2$,
\[
\Delta M_n = a_n S_n - a_{n-1} S_{n-1} = a_n Y_n - a_n \frac{S_{n-1}}{n-1} (2p - 1).
\]
Since $0 \leq Z_1 \leq C$, we have $\|S_{n-1}\|_\infty = \sum_{i=0}^{n-1} Z_i \leq (n - 1) C$. Thus for $n \geq 2$, it holds $\|\Delta M_n\|_\infty \leq 2C a_n$. This completes the proof of Lemma 7.1.

Denote by $\langle M \rangle_n$ the quadratic variation of $(M_n, \mathcal{F}_i)_{i \geq 1}$, that is
\[
\langle M \rangle_n = \sum_{i=1}^{n} \mathbb{E}[\Delta M_i^2 |\mathcal{F}_{i-1}].
\]

Lemma 7.2. Assume that $Z_1 \leq C$. Then, it holds for all $x > 0$,
\[
\mathbb{P}
\left(
\left|
\langle M \rangle_n - (\sigma^2 + 1) v_n
\right| \geq x v_n
\right)
\leq \begin{cases}
    c_1 \exp \left\{- c_2 x \frac{v_n}{a_n^2}\right\} & 0 < p < 1/2 \\
    0 & p = 1/2 \\
    c_1 \exp \left\{- c_2 (3 - 4p) v_n x\right\} & 1/2 < p < 3/4 \\
    c_1 \exp \left\{- c_2 v_n x\right\} & p = 3/4.
\end{cases}
\]
Proof. From (7.6), we get \( \Delta M_k = a_k \varepsilon_k = a_k (S_k - \gamma_{k-1} S_{k-1}) \). Thus, it holds
\[
E[\Delta M_k^2 | F_{k-1}] = a_k^2 E[(S_k - \gamma_{k-1} S_{k-1})^2 | F_{k-1}]
= a_k^2 (E[S_k^2 | F_{k-1}] - 2\gamma_{k-1} S_{k-1} E[S_k | F_{k-1}] + \gamma_{k-1}^2 S_{k-1}^2).
\]
It is easy to see that
\[
E[S_k^2 | F_{k-1}] = E[(S_k - \alpha_k \beta_k Z_k)^2 | F_{k-1}]
= S_{k-1}^2 + 2S_{k-1} E[\alpha_k \beta_k Z_k | F_{k-1}] + E[Z_k^2]
= S_{k-1}^2 + 2(2p-1) S_{k-1}^2 + (\sigma^2 + 1)
= (2\gamma_{k-1} - 1) S_{k-1}^2 + \sigma^2 + 1
\]
and
\[
E[S_k | F_{k-1}] = E[S_{k-1} + \alpha_k \beta_k Z_k | F_{k-1}] = S_{k-1} + \frac{2p-1}{k-1} S_{k-1} = \gamma_{k-1} S_{k-1}.
\]
Thus, we have \( E[\Delta M_k^2] = E[Z_k^2] = 1 + \sigma^2 \) and for \( k \geq 2 \),
\[
E[\Delta M_k^2 | F_{k-1}] = a_k^2 (2\gamma_{k-1} S_{k-1}^2 + \sigma^2 + 1 - 2\gamma_{k-1} S_{k-1}^2 + \gamma_{k-1}^2 S_{k-1}^2)
= a_k^2 (\sigma^2 + 1 - (\gamma_{k-1} - 1)^2 S_{k-1}^2)
= a_k^2 (\sigma^2 + 1 - (2p-1)^2 a_k^2 \frac{S_{k-1}^2}{k-1}). \tag{7.7}
\]
Since \( \frac{a_{n+1}}{a_n} \sim 1 \) as \( n \to \infty \) (cf. (7.1)), by the definitions of \( v_n \) and \( M_k \), we obtain
\[
\langle M \rangle_n = (\sigma^2 + 1)v_n - (2p-1)^2 \left( \sum_{k=1}^{n-1} \left( \frac{a_{k+1}}{a_k} \right)^2 \left( \frac{M_k}{k} \right)^2 \right)
= (\sigma^2 + 1)v_n - O(1) \sum_{k=1}^{n-1} \left( \frac{M_k}{k} \right)^2.
\]
From the last line, we have for all \( t \geq 1 \),
\[
\| \langle M \rangle_n - (\sigma^2 + 1)v_n \|_t \leq c_1 \sum_{k=1}^{n-1} \frac{M_k}{k} \| \frac{M_k}{k} \|_t \leq c_2 \sum_{k=1}^{n-1} \frac{1}{k^2} \| M_k \|_{2t}^2. \tag{7.8}
\]
Using Rio’s inequality (cf. Theorem 2.1 of [37]), we derive that for all \( t \geq 1 \),
\[
\| M_k \|_{2t}^2 \leq (2t-1) \sum_{i=1}^{k} \| \Delta M_i \|_{2t}^2.
\]
By the fact \( \| \Delta M_i \|_{\infty} \leq 2C a_i \) (cf. Lemma 7.1), we deduce that for all \( t \geq 1 \),
\[
\| M_k \|_{2t}^2 \leq (2t-1)4C^2 v_k.
\]
By (7.8) and (7.2), it is easy to see that for $0 < p < 3/4$, it holds for all $t \geq 1$,
\begin{align*}
\|\langle M \rangle_n - (\sigma^2 + 1)v_n\|_t & \leq 4c_2C^2(2t - 1) \sum_{k=1}^{n-1} \frac{1}{k^2} v_k \\
& \leq 4c_3C^2(2t - 1) \frac{(2p)^2}{3 - 4p} \sum_{k=1}^{n-1} k^{1-4p} \\
& \leq \begin{cases}
    c_4(2t - 1)n^{2(1-2p)} & 0 < p < 1/2 \\
    \frac{c_4}{3-4p}(2t - 1) & 1/2 < p < 3/4.
\end{cases} \tag{7.9}
\end{align*}

Similarly, by (7.8) and (7.3), when $p = 3/4$, we have
\begin{align*}
\|\langle M \rangle_n - (\sigma^2 + 1)v_n\|_t & \leq 4c_2C^2(2t - 1) \sum_{k=1}^{n-1} \frac{1}{k^2} \ln k \leq c_4(2t - 1).
\end{align*}

For $0 < p < 3/4$ and all $\lambda, x > 0$,
\begin{align*}
P\left(\|\langle M \rangle_n - (\sigma^2 + 1)v_n\| \geq xv_n\right) & \leq e^{-\lambda xv_n} E e^{|\langle M \rangle_n - (\sigma^2 + 1)v_n|} \\
& = e^{-\lambda xv_n} \sum_{t=0}^{\infty} \frac{\lambda^t}{t!} \|\langle M \rangle_n - (\sigma^2 + 1)v_n\|_t.
\end{align*}

For $0 < p < 1/2$, by the fact $n! \sim \sqrt{2\pi n}e^{-n}$ and inequality (7.9), we have for $\lambda = (4ec_4^{-2})^{-1}$ and all $x > 0$,
\begin{align*}
P\left(\|\langle M \rangle_n - (\sigma^2 + 1)v_n\| \geq xv_n\right) & \leq c_1 e^{-\lambda xv_n} \sum_{t=0}^{\infty} \frac{\lambda^t}{t!} (2t - 1)^t n^{2t(1-2p)} c_4^t \\
& \leq c_2 e^{-\lambda xv_n} \sum_{t=0}^{\infty} \frac{2^t \lambda^t}{t!} (a_n)^{2t} c_4^t \leq c_2 e^{-\lambda xv_n} \sum_{t=0}^{\infty} 2^t \lambda^t (a_n)^{2t} c_4^t \\
& \leq c_3 \exp \left\{- \frac{v_n x}{4ec_4 a_n^2} \right\}.
\end{align*}

When $p = 1/2$, by (7.7), we have
\begin{align*}
\langle M \rangle_n = (\sigma^2 + 1)v_n,
\end{align*}
which gives the desired inequality with $p = 1/2$. Similarly, for $1/2 < p < 3/4$, we have for $\lambda = (3 - 4p)(4ec_4^{-1})^{-1}$ and all $x > 0$,
\begin{align*}
P\left(\|\langle M \rangle_n - (\sigma^2 + 1)v_n\| \geq xv_n\right) & \leq c_1 e^{-\lambda xv_n} \sum_{t=0}^{\infty} \frac{\lambda^t}{t!} (2t - 1)^t c_4^t (3 - 4p)^{-t} \\
& \leq c_2 \exp \left\{- (3 - 4p) \frac{v_n x}{4ec_4} \right\}.
\end{align*}

For $p = 3/4$, it holds for $\lambda = (4ec_4)^{-1}$ and all $x > 0$,
\begin{align*}
P\left(\|\langle M \rangle_n - (\sigma^2 + 1)v_n\| \geq xv_n\right) & \leq c_1 e^{-\lambda xv_n} \sum_{t=0}^{\infty} \frac{\lambda^t}{t!} (2t - 1)^t c_4^t \\
& \leq c_2 \exp \left\{- \frac{v_n x}{4ec_4} \right\}.
\end{align*}

This completes the proof of Lemma 7.2. □
The following lemma is used in the proof of self-normalized type Cramér's moderate deviations.

**Lemma 7.3.** Assume that $Z_1 \leq C$. Then for all $x > 0$, it holds

$$
P \left( \left| \sum_{i=1}^{n} a_i^2 Z_i^2 - (\sigma^2 + 1)v_n \right| \geq x \right) \leq 2 \exp \left\{ - \frac{2x^2}{v_n C^2} \right\}.
$$

**Proof.** It is easy to see that

$$
\sum_{i=1}^{n} a_i^2 Z_i^2 - (\sigma^2 + 1)v_n = \sum_{i=1}^{n} a_i^2 (Z_i^2 - (\sigma^2 + 1)).
$$

Notice that

$$
-a_i^2 (\sigma^2 + 1) \leq a_i^2 (Z_i^2 - (\sigma^2 + 1)) \leq a_i^2 (C^2 - (\sigma^2 + 1)).
$$

The desired inequality is a simple consequence of Hoeffding' inequality (cf. Theorem 2 of [29]). This completes the proof of Lemma 7.3.

### 7.2. Proof of Theorem 3.1

Now we are in position to prove Theorem 3.1. Clearly, it holds

$$
\frac{a_n S_n}{\sqrt{(1 + \sigma^2)v_n}} = \frac{M_n}{\sqrt{(1 + \sigma^2)v_n}} = \sum_{i=1}^{n} \xi_i,
$$

where $\xi_i = \frac{\Delta M_i}{\sqrt{(1 + \sigma^2)v_n}}$, $i = 1, ..., n$. Then $(\xi_i, \mathcal{F}_i)_{i=1,...,n}$ is a finite sequence of martingale differences. By Lemma 7.1, we have

$$
\|\xi_i\|_{\infty} \leq 2C \max_{1 \leq i \leq n} \frac{a_i}{\sqrt{(1 + \sigma^2)v_n}} =: \epsilon_n.
$$

Using the inequalities (7.1)-(7.3), we deduce that

$$
\epsilon_n \asymp \begin{cases} 
\frac{n^{-1/2}}{\sqrt{3 - 4p} n^{(3 - 4p)/2}} & \text{if } 0 < p \leq 1/2 \\
\frac{\ln n}{-1/2} & \text{if } 1/2 < p < 3/4 \\
0 & \text{if } p = 3/4.
\end{cases}
$$

Moreover, from Lemma 7.2, we have for all $x > 0$,

$$
P \left( \left| \sum_{i=1}^{n} E(\xi_i^2 | \mathcal{F}_{i-1}) - 1 \right| \geq x \right) \leq \begin{cases} 
c_1 \exp \left\{ - c_2 \frac{\epsilon_n x}{a_n^2} \right\} & 0 < p < 1/2 \\
0 & p = 1/2 \\
c_1 \exp \left\{ - c_2 (3 - 4p)x \right\} & 1/2 < p < 3/4 \\
c_1 \exp \left\{ - c_2 \epsilon_n x \right\} & p = 3/4.
\end{cases}
$$

Using the inequalities (7.1)-(7.3), we deduce that for all $x > 0$,

$$
P \left( \left| \sum_{i=1}^{n} E(\xi_i^2 | \mathcal{F}_{i-1}) - 1 \right| \geq x \right) \leq c_1 \exp \left\{ - c_2 \epsilon_n^2 x \right\},
$$
where $\delta_n$ satisfies

$$
\delta_n = \begin{cases}
  n^{-1/2} & \text{if } 0 < p \leq 1/2 \\
  (3 - 4p)^{-1/2} n^{-(3-4p)/2} & \text{if } 1/2 < p < 3/4 \\
  (\ln n)^{-1/2} & \text{if } p = 3/4.
\end{cases} \quad (7.11)
$$

Applying Theorem 2.2 and Remark 2.1 to $a_n S_n / (1 + \sigma^2) \sqrt{v_n}$, we obtain the desired inequalities. This completes the proof of Theorem 3.1.

### 7.3. Proof of Theorem 3.2

Assume that $\varepsilon_x \in (0, 1/2]$. It is easy to see that for all $x \geq 0$,

$$
P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}) = P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}, \sum_{i=1}^{n} a_i^2 Z_i^2 \geq (1 - \varepsilon_x)(1 + \sigma^2) v_n) + P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}, \sum_{i=1}^{n} a_i^2 Z_i^2 < (1 - \varepsilon_x)(1 + \sigma^2) v_n) \leq P(a_n S_n \geq x \sqrt{(1 - \varepsilon_x)(1 + \sigma^2) v_n}) + P\left(\sum_{i=1}^{n} a_i^2 Z_i^2 - (1 + \sigma^2) v_n^2 < -\varepsilon_x (1 + \sigma^2) v_n\right) =: P_1 + P_2. \quad (7.12)
$$

By Theorem 3.1 and an argument similar to (5.14), we have for all $x \geq 0$,

$$
P_1 \leq \left(1 - \Phi(x \sqrt{1 - \varepsilon_x})\right) \exp\left\{c \left(\frac{x^3}{\sqrt{n}} + (1 + x) \frac{\ln n}{\sqrt{n}}\right)\right\} \leq \left(1 - \Phi(x)\right) \exp\left\{c \left(x \varepsilon_x + \frac{x^3}{\sqrt{n}} + (1 + x) \frac{\ln n}{\sqrt{n}}\right)\right\}. \quad (7.13)
$$

Using Lemma 7.3, we get for all $x \geq 0$,

$$
P_2 \leq 2 \exp\left\{-\frac{2(1 + \sigma^2)^2}{C^2} v_n \varepsilon_x\right\}. \quad (7.14)
$$

First, we consider the case $0 < p \leq 1/2$. Taking $\varepsilon_x = c_0 (x + \sqrt{\ln n}) / \sqrt{n}$ with $c_0$ large enough, by (7.2), (7.13) and (7.14), we deduce that for all $0 \leq x = o(\sqrt{n})$,

$$
P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}) \leq \left(1 - \Phi(x)\right) \exp\left\{c_1 \left(\frac{x^3}{\sqrt{n}} + (1 + x) \frac{\ln n}{\sqrt{n}}\right)\right\} + 2 \exp\left\{-c_2 c_0^2 (x + \sqrt{\ln n})^2 n^{2-4p}\right\}. \quad (7.15)
$$

Applying (5.12) to the last inequality, we obtain for all $0 \leq x = o(\sqrt{n})$,

$$
P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}) \leq \left(1 - \Phi(x)\right) \exp\left\{c_3 \left(\frac{x^3}{\sqrt{n}} + (1 + x) \frac{\ln n}{\sqrt{n}}\right)\right\}. \quad (7.15)$$
Next, we consider the case $1/2 < p \leq 3/4$. Taking $\varepsilon_x = c_0(x + \sqrt{\ln n})/\sqrt{v_n}$ with $c_0$ large enough, by an argument similar to the proof of (7.15), we get for all $0 \leq x = o(\sqrt{v_n})$,

$$
P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}) \leq \big(1 - \Phi(x)\big) \exp\left\{c_p \left(\frac{x^3}{\sqrt{v_n}} + (1 + x) \frac{\ln n}{\sqrt{v_n}}\right)\right\}.
$$

Then we obtain the desired upper bounds for the tail probability $P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2})$, $x \geq 0$. Notice that for all $x \geq 0$,

$$
P\left(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2}\right) \geq P\left(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2} - \sum_{i=1}^{n} a_i^2 Z_i^2 (1 + \varepsilon_x)(1 + \sigma^2)n\right) 
$$

$$
\geq P\left(a_n S_n \geq x \sqrt{(1 + \varepsilon_x)(1 + \sigma^2)v_n} - \sum_{i=1}^{n} a_i^2 Z_i^2 \leq x(1 + \sigma^2)v_n\right). 
$$

Thus the desired lower bounds for the tail probability $P(a_n S_n \geq x \sqrt{\sum_{i=1}^{n} a_i^2 Z_i^2})$, $x \geq 0$, can be obtained by a similar argument. The proof for $-a_n S_n$ follows by a similar argument. This completes the proof of Theorem 3.2.

8. Proofs of Theorem 3.3 and its corollaries

8.1. Proof of Theorem 3.3

By (3.13), we have $X_k = \sum_{i=0}^{k} \theta^{k-i} \varepsilon_i$. Taking into account that $|\theta| < 1$ and $|\varepsilon_n| \leq H$, we deduce that for all $k \geq 1$,

$$
|X_k| \leq H \sum_{i=0}^{k} |\theta|^{k-i} \leq \frac{H}{1 - |\theta|}.
$$

From (3.13), it is easy to see that

$$
\sum_{k=1}^{n} X_k X_{k-1} = \sum_{k=1}^{n} (\theta X_{k-1}^2 + X_{k-1} \varepsilon_k),
$$

from which we deduce that for all $n \geq 1$,

$$
\hat{\theta}_n - \theta = \frac{\sum_{k=1}^{n} X_{k-1} \varepsilon_k}{\sum_{k=1}^{n} X_{k-1}^2}.
$$

(8.1)

For any $i \geq 1$, denote by

$$
\eta_i = X_{i-1} \varepsilon_i, \quad S_n = \sum_{i=1}^{n} \eta_i \quad \text{and} \quad F_i = \sigma(\varepsilon_k, 0 \leq k \leq i).
$$

Then $(\eta_i, F_i)_{i \geq 1}$ is a sequence of martingale differences and satisfies

$$
|\eta_i| \leq \frac{H^2}{1 - |\theta|} \quad \text{and} \quad \langle S \rangle_n = \sum_{i=1}^{n} E(\eta_i^2 | F_{i-1}) = \sigma^2 \sum_{i=1}^{n} X_{i-1}^2.
$$
By some simple calculations, we get

\[ ES^2_n = \sigma^2 E \sum_{i=1}^{n} X_{i-1}^2 = \sigma^4 \sum_{i=1}^{n} \vartheta^{2(i-j)} = \frac{n\sigma^4}{1-\vartheta^2} \left( 1 + \frac{\vartheta^{2(n+2)}}{n(1-\vartheta^2)} \right) \sim \frac{n\sigma^4}{1-\vartheta^2}, \quad n \to \infty. \]

Using Doob’s decomposition theorem, we have

\[ \sum_{i=1}^{n} X_{i-1}^2 - E \left( \sum_{i=1}^{n} X_{i-1}^2 \right) = \sum_{k=1}^{n} M_k, \]

where

\[ M_k = E \left( \sum_{i=k+1}^{n} X_{i-1}^2 \mid \mathcal{F}_k \right) - E \left( \sum_{i=k+1}^{n} X_{i-1}^2 \mid \mathcal{F}_{k-1} \right). \]

Notice that \((M_k, \mathcal{F}_k)_{0 \leq k \leq n}\) is a finite sequence of martingale differences. It is easy to see that

\[ M_k = E \left( \sum_{i=k+1}^{n} X_{i-1}^2 \mid \mathcal{F}_k \right) - E \left( \sum_{i=k+1}^{n} X_{i-1}^2 \mid \mathcal{F}_{k-1} \right) = \sum_{i=k+1}^{n} \left( 2\varepsilon_k \varepsilon_{k-1} \vartheta^{2i-2k-1} + (\varepsilon_k^2 - E \varepsilon_k^2) \vartheta^{2i-2k-2} \right) \]

and that

\[ |M_k| \leq \sum_{i=k+1}^{n} \left( 2M^2 \vartheta + M^2 \right) \vartheta^{2i-2k-2} \leq \frac{2|\vartheta| + 1}{1-\vartheta^2} M^2. \]

By Azuma-Hoeffding’s inequality, we have for all \(x > 0,\)

\[ P \left( \left| \sum_{i=1}^{n} X_{i-1}^2 - E \left( \sum_{i=1}^{n} X_{i-1}^2 \right) \right| \geq x \right) \leq \exp \left\{ -\frac{x^2}{2nM^2 \vartheta} \right\}. \]

Recall that \(\sigma^{-2} ES^2_n \sim \frac{n\sigma^2}{1-\sigma^2}\) as \(n \to \infty.\) The last inequality implies that for all \(x > 0,\)

\[ P \left( \left| \frac{\langle S \rangle_n}{ES^2_n} - 1 \right| \geq x \right) \leq \exp \left\{ -C_{M,|\vartheta|,\sigma} n x^2 \right\}. \]

By (8.1), we have

\[ \frac{1}{\sigma} (\hat{\vartheta}_n - \vartheta) \left\lVert \sum_{i=1}^{n} X_{i-1}^2 \right\rVert = \frac{S_n}{\sqrt{\langle S \rangle_n}}. \]

Clearly, \((\eta_i / \sqrt{ES^2_n}, \mathcal{F}_i)_{i \geq 1}\) satisfies the conditions (A1) and (A2) with \(\epsilon_n = O(1/\sqrt{n})\) and \(\delta_n = O(1/\sqrt{n}).\) Thus the desired inequality follows from Theorem 3.3.
8.2. Proof of Corollary 3.2

By Theorem 3.3, we have for all $0 \leq x = o(n^{1/6})$,

\[
P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} > x \right) = 1 + o(1) \quad \text{and} \quad P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} < -x \right) = 1 + o(1). \tag{8.2}
\]

Clearly, by (3.16), the upper $(\kappa_n/2)$th quantile of a standard normal distribution

\[
\Phi^{-1}(1 - \kappa_n/2) = -\Phi^{-1}(\kappa_n/2) = O(\sqrt{\ln \kappa_n})
\]

is of order $o(n^{1/6})$. Applying the last equality to (8.2), we have

\[
P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} > \Phi^{-1}(1 - \kappa_n/2) \right) \sim \kappa_n/2 \tag{8.3}
\]

and

\[
P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} < -\Phi^{-1}(1 - \kappa_n/2) \right) \sim \kappa_n/2, \quad n \to \infty. \tag{8.4}
\]

Clearly, $\frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} \leq \Phi^{-1}(1 - \kappa_n/2)$ implies that $\theta \geq A_n$, while $\frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} \geq -\Phi^{-1}(1 - \kappa_n/2)$ means $\theta \leq B_n$. Thus $[A_n, B_n]$ is a $1 - \kappa_n$ confidence interval for $\theta$, for $n$ large enough.

8.3. Proof of Corollary 3.3

By Theorem 3.3, we have for all $0 \leq x = o(n^{1/2})$,

\[
P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} > x \right) = \exp \left\{ \theta_1 C \frac{\ln n + x^3}{\sqrt{n}} \right\}, \tag{8.5}
\]

and

\[
P\left( \frac{1}{\sigma}(\hat{\theta}_n - \theta) \sqrt{\sum_{k=1}^{n} X_k^2} < -x \right) = \exp \left\{ \theta_2 C \frac{\ln n + x^3}{\sqrt{n}} \right\}. \tag{8.6}
\]

where $\theta_1, \theta_2 \in [-1, 1]$. Notice that

\[
1 - \Phi(x_n) \sim \frac{1}{x_n \sqrt{2\pi}} e^{-x_n^2/2} = \exp \left\{ - \frac{x_n^2}{2} \right\} \left( 1 + \frac{2}{x_n} \ln(x_n \sqrt{2\pi}) \right), \quad x_n \to \infty.
\]

Thus, when $k_n \to 0$, the upper $(\kappa_n/2)$th quantile of the distribution

\[
1 - \left( 1 - \Phi(x) \right) \exp \left\{ \theta_1 C \frac{\ln n + x^3}{\sqrt{n}} \right\}
\]

has an order of $\sqrt{2 \ln(\kappa_n/2)}$, which by (3.17) is of order $o(\sqrt{n})$ as $n \to \infty$. Then by an argument similar to the proof of Corollary 3.2, we obtain the desired result.
