Stability and Generalization of Differentially Private Minimax Problems

Yilin Kang, Yong Liu, Jian Li, Weiping Wang

Abstract

In the field of machine learning, many problems can be formulated as the minimax problem, including reinforcement learning, generative adversarial networks, and more. However, in general minimax setting, combining differential privacy together with minimax optimization paradigm. Besides, via algorithmic stability theory, we theoretically analyze the high probability generalization performance of the differentially private minimax algorithm under the strongly-convex-strongly-concave condition. To the best of our knowledge, this is the first time to analyze the generalization performance of general minimax paradigm, taking differential privacy into account.

In the field of machine learning, many problems can be formulated as the minimax problem, including adversarial learning (Goodfellow et al. 2014), reinforcement learning (Du et al. 2017; Dai et al. 2018), AUC maximization (Zhao et al. 2011; Gao et al. 2013; Ying, Wen, and Lyu 2016; Lei et al. 2018), robust optimization (Chen et al. 2017; Namkoong and Duchi 2017), and distributed computing (Shamma 2008; Mateos, Bazerque, and Giannakis 2010; Razaviyayn et al. 2020), to mention but a few. In the minimax problem, there are two groups of decision variables: one for minimization and one for maximization (Lei et al. 2021). To solve the minimax problem, various optimization algorithms have been designed, such as Gradient Descent Ascent (GDA), Stochastic Gradient Descent Ascent (SGDA), Alternating Gradient Descent Ascent (AGDA), Proximal Point Method (PPM), etc (Farnia and Ozdaglar 2021; Lei et al. 2021)

Like other machine learning problems, the minimax problem also faces the privacy troubles, because tremendous individual’s data have to be collected for training (Phan et al. 2020; Wang et al. 2021b). In the real scenarios, not only the original data leakages the sensitive information, the machine learning model also causes privacy issues (Fredrikson et al. 2017). Under these circumstances, Dwork et al. 2006 proposes a theoretically rigorous tool: Differential Privacy (DP) Dwork and Roth 2014, to protect the sensitive information of individuals who participate in the training dataset, by introducing random noise to the model. There are mainly three approaches to guarantee DP: output perturbation, objective perturbation, and gradient perturbation (Chaudhuri, Monteleoni, and Sarwate 2011; Song, Chaudhuri, and Sarwate 2013). There exist some works to combine differential privacy with some of the minimax problems, such as DP-adversarial learning (Xu et al. 2019; Phan et al. 2020; Giraldo et al. 2020; Lin, Sekar, and Fanti 2021), DP-reinforcement learning (Vietri et al. 2020; Chen et al. 2021a), DP-AUC maximization (Huai et al. 2020; Wang et al. 2021b; Yang et al. 2021), and DP-robust optimization (Lecuyer et al. 2019). However, all the researches mentioned above only focus on particular models (e.g. Generative Adversarial Networks (GANs)), but not on the general minimax paradigm. Besides, there is no analysis on the generalization error of the general DP-minimax model to the best of our knowledge.

To solve these problems, in this paper, we concentrate on differentially private minimax optimization, provide privacy guarantees and analyze the generalization performance of the DP minimax model (we pay more attentions on the generalization part). Due to the simplicity, GDA is one of the most widespread used optimization methods in the field of minimax problem, so we focus on GDA in this paper. Besides, considering that the high probability generalization performance of machine learning models is paid more attentions, we use algorithmic stability theory, in particular, argument stability, to get several different generalization measures of DP-GDA model, under high probability condition. The contributions of this paper include: 1. In the minimax problem, there are two decision variables: one for minimization and one for maximization, so there are various generalization measures due to different coupling combinations (Farnia and Ozdaglar 2021; Lei et al. 2021; Zhang et al. 2021). In this paper, we analyze almost all existing generalization measures for our proposed DP-GDA algorithm, via algorithm stability theory and pro-
vide corresponding high probability bounds. And our results are better than previous results analyzed for particular DP-minimax model (such as DP-AUC maximization). To the best of our knowledge, this is the first time to give generalization bounds for the general minimax paradigm. 2. In the minimax problem, the minimization parameter $w$ differs when it comes to different maximization parameters $v$ (and vice versa), which brings challenges to the theoretical analysis. Moreover, for differentially private models, random noise is an essential part and it makes the results worse. In this paper, to overcome these problems, novel decomposition methods are applied and sharper generalization bounds are achieved.

The rest of the paper is organized as follows. The related work is discussed in Section 2. Preliminaries are introduced in Section 3. The algorithm DP-GDA along with the privacy guarantees are given in Section 4. We analyze the generalization performance of DP-GDA in Section 5. We compare our results with existed works in Section 6. Finally, we conclude the paper in Section 7. And all the proofs are given in the Appendix.

**Related Work**

For the minimax problem, there is a long list of works discussing the convergence analysis and the empirical risk under convex-concave condition \cite{Mokhtari, Ozdaglar, and Pattathil 2020; Yer et al. 2020; Lin, Jin, and Jordan 2020a; Wang and Li 2020; Yoon and Ryu 2021; nonconvex-concave condition \cite{Luo et al. 2020; Lu et al. 2020; Lin, Jin, and Jordan 2020b; Chen et al. 2021b; and nonconvex-nonconcave condition \cite{Loizou et al. 2020; Yang, Kiyavash, and He 2020; Wang, Zhang, and Ba 2020; Liu et al. 2021; Diakonikolas, Daskalakis, and Jordan 2021; Loizou et al. 2021; Fiez and Ratliff 2021}. However, there is relatively little work concerning the generalization performance. \cite{Zhang et al. 2021} analyzes the generalization performance of the empirical saddle point (ESP) solution in the minimax problem; \cite{Farnia and Ozdaglar 2021} discusses the generalization performance of several popular optimization algorithms in the minimax problem: GDA, GDmax, SGDA, SGDmax, and PPM. And \cite{Zhang et al. 2021} and \cite{Farnia and Ozdaglar 2021} only focus on the expectation generalization bounds. Besides, \cite{Lei et al. 2021} gives high probability generalization bounds, of the order $O(1/\sqrt{n})$, where $n$ is the number of training data.

To analyze the generalization performance, complexity theory \cite{Bartlett, Bousquet, and Mendelson 2002} and algorithmic stability \cite{Bousquet and Elisseeff 2002} are popular tools. On one hand, some existed works analyze the generalization performance of differentially private models via complexity theory. For example, \cite{Chaudhuri, Monteleoni, and Sarwate 2011} gives high probability excess population risk bound under strongly convex conditions and \cite{Kifer, Smith, and Thakurta 2012} gives the excess population risk bound in expectation. On the other hand, algorithmic stability is a fundamental concept in learning theory, and it captures the fluctuations on the model caused by modifying one of the data instances. Algorithmic stability has been widely studied in recent decades, including uniform stability \cite{Bousquet and Elisseeff 2002; Hardt, Recht, and Singer 2016}, hypothesis stability \cite{Bousquet and Elisseeff 2002}, argument stability \cite{Li et al. 2017; Bassily et al. 2020}, locally elastic stability \cite{Deng, He, and Su 2021}. And there is a long list of works analyzing the high probability generalization bounds for differentially private models via algorithmic stability \cite{Wu et al. 2017; Bassily et al. 2019; Feldman, Koren, and Talwar 2020; Bassily et al. 2020; Wang et al. 2021b}. Besides, \cite{Lei et al. 2021; Farnia and Ozdaglar 2021; Zhang et al. 2021} have extended the uniform stability and argument stability to the minimax setting, and a new stability concept: weakly stability is designed for the minimax problem in \cite{Lei et al. 2021}. However, the analysis on the generalization performance of DP-minimax problem is still a blank.

Meanwhile, there are some works combining differential privacy with some particular minimax problems. \cite{Xu et al. 2019} designs GANobfuscator, which guarantees DP of GAN via gradient perturbation method. Besides, \cite{Giraldo et al. 2020} discusses the inherent privacy of GANs, from the view of DP. However, these works do not give any theoretical utility guarantees. \cite{Wang et al. 2021b} proposes output and objective perturbation methods to guarantee the differential privacy of AUC maximization, and achieves $O(1/\sqrt{n})$ high probability excess population risk bound. Considering that AUC maximization can be seen as one of the pairwise learning problems, \cite{Hua et al. 2020; Yang et al. 2021} analyze the privacy guarantees and the generalization bounds of DP-AUC maximization from the pairwise perspective, they also achieve excess population risk bound of the order $O(1/\sqrt{n})$ with high probability. For reinforcement learning, \cite{Chen et al. 2021a} proposes a DP version on the platform Vehicular ad hoc network (VANET), and \cite{Vietri et al. 2020} not only discusses the privacy, but also gives the probably approximately correct (PAC) and regret bounds. However, to the best of our knowledge, there is no existing work concentrating on DP of the general minimax problem.

**Preliminaries**

**Differential Privacy**

Let $\mathcal{P}$ be a probability measure defined on the data space $\mathcal{Z}$ and let dataset $S = \{z_1, \cdots, z_n\}$ be independent drawn from $\mathcal{P}$. Datasets $S, S'$ differing by at most one data instance are denoted by $S \sim S'$, called adjacent datasets.

**Definition 1.** \cite{Dwork and Roth 2014} Algorithm $\mathcal{A} : \mathcal{Z}^n \rightarrow \mathbb{R}^p$ is $(\epsilon, \delta)$-differential privacy (DP) if for all $S \sim S'$ and events $O \in \text{range}(\mathcal{A})$

$$\mathbb{P} [\mathcal{A}(S) \in O] \leq e^\epsilon \mathbb{P} [\mathcal{A}(S') \in O] + \delta.$$  

Differential privacy requires essentially the same distributions to be drawn over any adjacent datasets, so that the adversaries cannot infer whether an individual participates to the training process. Some kind of attacks, such as attribute
Minimax Paradigm

Denote two parameter spaces as $W, V \in \mathbb{R}^p$, where $p$ is the parameter dimensions, then for the minimax problem, we define $\ell : W \times V \times Z \rightarrow \mathbb{R}$ and consider

$$
\min_{w} \max_{v} L(w, v) := \mathbb{E}_{z \sim \mathcal{P}} [\ell(w, v; z)].
$$

Since the underlying $\mathcal{P}$ is always unknown, so empirical risk is designed as

$$
L_S(w, v) = \frac{1}{n} \sum_{i=1}^{n} \ell(w, v; z_i).
$$

Denoting the model derived from dataset $S$ by applying algorithm $A$ as $A(S) = (A_w(S), A_v(S)) \in W \times V$, in this paper, we focus on analyzing how well $A(S)$ performs on the underlying distribution $\mathcal{P}$, i.e. the generalization performance. There are several measures to demonstrate the generalization performance of the minimax model.

**Definition 2 (Lei et al. 2021).** There are four generalization measures in the minimax problem.

(a) **Weak Primal-Dual (PD) Risk:** The weak PD population risk of $(w, v)$ is defined as

$$
\triangle^w(w, v) = \sup_{v' \in V} \mathbb{E} [L(w, v')] - \inf_{w' \in W} \mathbb{E} [L(w', v)].
$$

Corresponding empirical risk is defined as

$$
\triangle_S^w(w, v) = \sup_{v' \in V} \mathbb{E} [L_S(w, v')] - \inf_{w' \in W} \mathbb{E} [L_S(w', v)].
$$

$\triangle^w(w, v) - \triangle_S^w(w, v)$ is referred to the weak PD generalization error of $(w, v)$.

(b) **Strong Primal-Dual (PD) Risk:** The strong PD population risk of $(w, v)$ is defined as

$$
\triangle^s(w, v) = \sup_{v' \in V} L(w, v') - \inf_{w' \in W} L(w', v).
$$

Corresponding empirical risk is defined as

$$
\triangle_S^s(w, v) = \sup_{v' \in V} L_S(w, v') - \inf_{w' \in W} L_S(w', v).
$$

$\triangle^s(w, v) - \triangle_S^s(w, v)$ is referred to the strong PD generalization error of the model $(w, v)$.

(c) **Primal Risk:** The primal population risk and empirical risk are w.r.t model $w$, defined as

$$
R(w) = \sup_{v \in V} L(w, v), \quad R_S(w) = \sup_{v \in V} L_S(w, v).
$$

If $R(w)$ is bounded by $R_S(w)$, we call this error the primal generalization error; if $R(w)$ is bounded by $\inf_{w' \in W} R(w')$, we call this error the excess primal population risk.

(d) **Plain Risk:** For model $(w, v)$, if $L(w, v)$ is bounded by $L_S(w, v)$, this error is called the plain generalization error.

**Remark.** In Definition 2, the primal risk is w.r.t only one of the parameters $w$ and the plain risk are similar to which in traditional learning tasks. Besides, for weak and strong PD risks, one can easily get $\triangle^w(w, v) \leq \mathbb{E} [\triangle^s(w, v)]$ and $\triangle_S^w(w, v) \leq \mathbb{E} [\triangle_S^s(w, v)]$, so the weak PD risk is naturally bounded by the strongly PD risk bound.

For a $p$-dimension vector $x$, define its $\ell_2$ norm (Euclidean norm) as $\|x\|_2 = (\sum_{i=1}^{p} |x_i|^2)^{1/2}$, and let $\langle \cdot, \cdot \rangle$ be the inner product. A differentiable function $\ell : W \rightarrow \mathbb{R}$ is called $\rho$-strongly-convex over $w$ if for any $w, w'$

$$\ell(w) - \ell(w') \geq \langle \nabla \ell(w'), w - w' \rangle + \frac{\rho}{2} \|w - w'\|^2.$$

If $-\ell$ is $\rho$-strongly convex, then $\ell$ is $\rho$-strongly concave.

**Assumption 1.** For the minimax problem, we say $\ell$ is $\rho$-strongly-convex-$\rho$-strongly-concave ($\rho$-SC-SC) if $\ell(\cdot, v)$ is $\rho$-strongly-convex for all $v$ and $\ell(w, \cdot)$ is $\rho$-strongly-concave for all $w$. In this paper, we focus on the $\rho$-SC-SC problem.

**Assumption 2.** For $G > 0$, $\ell(w, v; z)$ is $G$-Lipschitz if for any $w, v$ and $z$

$$
\| \nabla_w \ell(w, v; z) \|_2 \leq G, \quad \| \nabla_v \ell(w, v; z) \|_2 \leq G.
$$

**Assumption 3.** For $L > 0$, $\ell(w, v; z)$ is $L$-smooth if for any $w, v, v'$ and $z$

$$
\begin{align*}
& \| \nabla_w \ell(w, v; z) - \nabla_w \ell(w', v; z) \|_2 \leq L \| w - w' \|_2, \\
& \| \nabla_v \ell(w, v; z) - \nabla_v \ell(w', v; z) \|_2 \leq L \| v - v' \|_2, \\
& \| \nabla_v \ell(w, v; z) - \nabla_v \ell(w', v; z) \|_2 \leq L \| v - v' \|_2.
\end{align*}
$$

**Algorithmic Stability**

Algorithmic stability is a popular tool to analyze the generalization performance of the machine learning model, which captures the difference between models derived from adjacent training datasets. Some of the stabilities have been extended to the minimax problem, such as weakly stability, uniform stability and argument stability, in expectation or high probability [Zhang et al. 2021, Lei et al. 2021, Farnia and Ozdaglar 2021].

In this paper, we use argument stability to get the high probability generalization bounds, defined as follows.

**Definition 3.** Algorithm $A$ is $\gamma$-argument-stable ($\gamma > 0$) if for any adjacent datasets $S \sim S' \in \mathbb{Z}^n$ we have

$$
\| A_w(S) - A_w(S') \|_2 + \| A_v(S) - A_v(S') \|_2 \leq \gamma.
$$

In the minimax problem, argument stability demonstrates the gap between $A(S)$ and $A(S')$, formulated by the summation over $w$ and $v$. Via property $G$-Lipschitz (Assumption 2), it directly derives the uniform stability.

**Differentially Private Gradient Descent Ascent**

Among many optimization methods designed for the minimax problem, Gradient Descent Ascent (GDA) is one of the most widespread algorithms because of its simplicity, so we concentrate on GDA in this paper.
Algorithm 1 Differentially Private Gradient Descent Ascent

**Input:** dataset $S$, privacy budgets $\epsilon, \delta$, learning rates $\eta_t$.

Initialize $w_1, v_1 = 0$.

for $i = 1$ to $T$ do

Sample $b_w, b_v \sim \mathcal{N}(0, \sigma^2 I_p)$.

$w_{t+1} = \text{Proj}_W (w_t - \eta_t (\nabla_w L_S(w_t, v_t) + b_w))$.

$v_{t+1} = \text{Proj}_Y (v_t + \eta_t (\nabla_v L_S(w_t, v_t) + b_v))$.

end for

$w_T = \frac{1}{T} \sum_{t=1}^T w_t, \quad v_T = \frac{1}{T} \sum_{t=1}^T v_t$.

Return $A(S) = (w_T, v_T)$.

Let $w_1, v_1 = 0$ be the initial model, $\eta_t$ be the learning rate at iteration $t$ ($t = 1, \ldots, T$), and $\text{Proj}()$ be projection to the corresponding parameter spaces, then

$w_{t+1} = \text{Proj}_W (w_t - \eta_t (\nabla_w L_S(w_t, v_t)))$,

$v_{t+1} = \text{Proj}_Y (v_t + \eta_t (\nabla_v L_S(w_t, v_t)))$.

To guarantee DP, we propose DP-GDA in Algorithm 1. In Algorithm 1, the output is the average of iterates $w_T$ and $v_T$, rather than $w_T$ and $v_T$ themselves. The reason is that the average operator simplifies the optimization error analysis (Nemirovski et al. 2009; Lei et al. 2021).

Before giving the privacy guarantees of Algorithm 1, we first recall the DP property in the single parameter setting.

**Lemma 1.** (Wang, Ye, and Xu 2017) In single parameter DP gradient descent paradigm whose model updating process is $w_{t+1} = \text{Proj}_W (w_t - \eta_t (\nabla_w L_S(w_t)))$ and the loss function is $\mathcal{G}$-Lipschitz, for $\epsilon, \delta > 0$, it is $(\epsilon, \delta)$-DP if the random noise is zero mean Gaussian noise, i.e., $b \sim \mathcal{N}(0, \sigma^2 I_p)$, and for some constant $c, \sigma^2 = c \frac{G^2 T \log(1/\delta)}{n\epsilon^2} \cdot$

By Lemma 1, we give the privacy guarantees of DP-GDA.

**Theorem 1.** If $\ell(\cdot, \cdot; \cdot)$ satisfies Assumption 4 then for $\epsilon, \delta > 0$, DP-GDA is $(\epsilon, \delta)$-DP if

$$\sigma = \mathcal{O} \left( \frac{G \sqrt{T \log(1/\delta)}}{n \epsilon} \right) \cdot$$

Theorem 1 is directly derived from Lemma 1. For differentially private gradient descent under single parameter condition, (Wang, Ye, and Xu 2017) gives a tight noise bound (as shown in Lemma 1), via moments accounting theory (Abadi et al. 2016). In the minimax paradigm, it is also the gradient who may cause the privacy leakage when training, similar to the condition analyzed in (Wang, Ye, and Xu 2017). And the privacy cost is independent of the minimization or maximization processes. As a result, if the noise given in (Wang, Ye, and Xu 2017) is injected to both $w$ and $v$, the claimed DP will be guaranteed. This is also the reason that $w$ and $v$ share the same variance in Theorem 1. Besides, we average the parameters at the end of the algorithm, this will not effect the claimed DP because of the Post-Processing property of differential privacy (Dwork and Roth 2014). Considering that the proof process is almost the same (the only difference is to apply it to $v$ once more) and we focus more on the generalization analysis in this paper, we directly use the result here in Algorithm 1. For clarity, we give the proof in Appendix A.1.

**Remark 2.** In Algorithm 1, we apply gradient perturbation method to guarantee DP, rather than output or objective perturbation methods. One of the reasons is that gradient perturbation naturally fits gradient-based algorithms (such as GDA), and as a result it can be used for a wide range of applications. Besides, adding random noise to the gradient allows the model to escape local minima (Raginsky, Rakhlin, and Telgarsky 2017). So we choose gradient perturbation method to guarantee DP in this paper.

**Generalization Performance**

In this section, we analyze the stability of DP-GDA and then give corresponding generalization bounds. To get the generalization bounds, we further assume that the loss function and the parameter space are bounded.

**Assumption 4.** The loss function $\ell(\cdot, \cdot; \cdot)$ is assumed to be bounded, i.e., $0 \leq \ell(\cdot, \cdot; \cdot) \leq M$. (Wang, Ye, and Xu 2017)

**Assumption 5.** Parameter spaces are assumed to be bounded: for all $w$ and $v$, $\|w\|_2 \leq M_w$ and $\|v\|_2 \leq M_v$.

**Stability Analysis**

Firstly, we analyze the argument stability (defined in Definition 3) of our proposed DP-GDA.

**Theorem 2.** If Assumptions 2 and 4 hold. Then with $\sigma$ given in Theorem 1 and $\eta_t = \frac{1}{\rho T}$, the output of DP-GDA (Algorithm 1) $A(S) = (w_T, v_T)$ is $\gamma$-argument stable with probability at least $1 - \frac{\gamma}{\gamma}$ for $\gamma \in (\exp(-\frac{\gamma}{\gamma}), 1)$, where

$$\gamma = \frac{4G}{np} + \frac{2\sqrt{p} \sqrt{T \log(eT)}}{T} \frac{\rho_c}{\rho} + 4 \sqrt{\log(eT)} \times \sqrt{\frac{G^2}{p^2 T} + \frac{\sigma^2}{p^2 T} \frac{1}{\rho^2} + 2 \frac{G \sigma}{p^2 T} \frac{1}{\rho^2} \frac{\rho_c}{\rho} \sqrt{T \log(eT)} \frac{\rho_c}{\rho} \cdot$$

where $p_c = 1 + \frac{(\sqrt{T \log(eT)})^{1/4}}{/(\sqrt{T \log(eT)})^{1/4}}$, $g_w = \|w^* - w_T\|_2$, and $g_v = \|v^* - v_T\|_2$ for $w^* = \arg \min_{w \in W} L_S(w, v_T)$ and $v^* = \arg \max_{v \in V} L_S(w, v)$. The proof can be found in Appendix A.2. We first compare it with non-DP minimax problem. The key difference is that in DP-GDA, random noise is an essential part, which brings challenges to the theoretical analysis if we want an acceptable stability bound. In the non-DP setting, if we set $T$ larger, the stability bound will be better in general, however, in DP-GDA, this is not true because the $T$-time injected random noise also affects the stability. Then, we compare it with traditional single parameter problem under DP condition. When it comes to the DP setting, there exist terms $\|b\|_2$ and $\|b\|_2^2$ (in the minimax problem, they are divided into $b_w$ and $b_v$). Among them, $\|b\|_2^2$ is an acceptable term because the variance of $b$ is of the order $\mathcal{O}(1/n) \text{ w.r.t } n$, so
the key challenge is to bound $\|b\|_2$, especially for high probability bounds (in expectation bounds, $\mathbb{E}[\|b\|_2^2] = 0$). In traditional DP settings, factor $\|b\|_2$ can be eliminated by choosing particular $\eta$ (for example, in Wang, Ye, and Xu (2017), term $\|b\|_2$ vanishes by setting $\eta = 1/L$, where $L$ is the smoothness parameter). However, in the minimax paradigm, this cannot go through because parameter $\nu$ differs with the changing of $\nu$ (and vice versa), which brings huge troubles to the theoretical analysis. To solve the problems mentioned above, we introduce terms $g_w, g_v$ to bound $\|b_w\|_2$ and $\|b_v\|_2$, respectively. Meanwhile, if we bound $g_w, g_v$ rudely by $M_w$ and $M_v$, the result will be worse, detailed discussions are shown in Remark 4.

**Remark 3.** In Theorem 2 there exist terms $g_w, g_v$, we discuss them here. With $\rho$-strongly convexity, we have $\rho g_w^2 \leq 2(L_S(\mathbf{w}, \nu_T) - L_S(\mathbf{w}^*, \nu_T))$. By extending the classical analysis of the gradient descent model (see e.g. (Shalev-Shwartz and Ben-David 2014)), if Assumptions 1, 2 and 5 hold, then with $\eta = \frac{1}{\rho}$, we have

$L_S(\mathbf{w}_t, \nu_T) - L_S(\mathbf{w}^*, \nu_T) \leq \log(eT) \left( \frac{G^2}{2\rho T} + \left( \frac{G}{T} + \frac{M_w \sigma \log(eT)}{\rho} \right) \|b_w\|_2 + \|b_w\|_2 \frac{\sigma^2 p}{\rho^2 T^2} \right)\cdot$

So with probability at least $1 - \zeta$ for $\zeta (\exp(-\frac{T}{4}), 1)$,

$g_w \leq \sqrt{\log(e)} \times \frac{\sqrt{G^2}}{\rho^2 T} + \frac{G \sigma}{\sqrt{T}} + \frac{M_w \sigma}{\rho^2 T^2} \left( \frac{\sigma^2 p}{\rho^2 T} \right) + \frac{\sigma^2 p}{\rho^2 T^2} \cdot$

where $p^*_c = 1 + (\frac{\sqrt{\log(T)} T}{\zeta})^{1/4}$.

Similarly, under Assumptions 1 and 3, $g_v$ shares the same property with high probability. Taking $\sigma$ given in Theorem 1 and omitting log($\cdot$) terms, we have

$g_w, g_v = O \left( \frac{1}{T} + \frac{\sqrt{p}}{n \sqrt{T} \epsilon} + \frac{\sqrt{p T}}{n \epsilon} + \frac{\sqrt{p}}{n^2 \epsilon^2} \right)$.

If taking $T = O(n^{1/3})$, then with high probability, we have $g_w, g_v = O \left( \frac{1}{n^{3/4}} \right)$.

**Remark 4.** Taking $\sigma$ in Theorem 2 and $T = O(n^{1/3})$, then with high probability, we have $\gamma = O \left( \frac{1}{n^{1/4}} \right)$.

Then we can answer the question left above, if we do not bound term $\|b_w\|_2$ and $\|b_v\|_2$ with $g_w, g_v$, but 'rudely' using $M_w$ and $M_v$, then the stability bound comes to

$\gamma = \frac{4G}{\rho^2 T} + \frac{2G \sigma \sqrt{T}}{\rho^2 T} \gamma + \left( M_w + M_v \right) \sigma \sqrt{T} \gamma + \frac{4 \sigma^2 p}{\rho^2 T^2} \gamma \cdot$

Under this condition, if we take $T = O(n^{1/3})$ and Assumption 5 holds, the stability bound comes to $\gamma = O \left( \frac{1}{n^{1/4}} \right)$. Thus, by introducing $g_w$ and $g_v$, we improve the stability bound from $O \left( \frac{1}{n^{1/4}} \right)$ to $O \left( \frac{1}{n^{1/2}} \right)$.

**Utility Bounds via Stability**

In this section, we connect different generalization measures listed in Definition 2 with the argument stability and give corresponding risk bounds.

**Theorem 3.** With argument stability parameter $\gamma$,

(a) If Assumptions 2 and 4 hold, then for all $\eta, \zeta > 0$, with probability at least $1 - \zeta$, the plain generalization error satisfies

$L(A_w(S), A_v(S)) - \frac{1}{1 - \eta} L_s(A_w(S), A_v(S)) \leq \sqrt{\left( \frac{G^2 \gamma^2 + 64 G^2 n \gamma^2 \log \left( \frac{3 \eta}{\zeta} \right)}{2 \left( 1 - \eta \right)^2 n} \right)} \log \left( \frac{3}{\zeta} \right) + \frac{50 \sqrt{2} G \gamma \log(n)}{1 - \eta} \log \left( \frac{3 e}{\zeta} \right) + \frac{(12 + 2\zeta) M_t}{3(1 - \eta)n} \log \left( \frac{3}{\zeta} \right)$.

(b) If Assumptions 2 and 5 hold, then for all $\eta, \zeta > 0$, with probability at least $1 - \zeta$, the primal generalization error satisfies

$R(A_w(S)) - \frac{1}{1 - \eta} R_s(A_w(S)) \leq \sqrt{\left( \frac{1 + L/\rho \gamma^2 (1 + 64 n \log \left( \frac{3 \eta}{\zeta} \right))}{2 \left( 1 - \eta \right)^2 n} \right)} \log \left( \frac{3}{\zeta} \right) + \frac{50 \sqrt{2} (1 + L/\rho) G \gamma \log(n)}{1 - \eta} \log \left( \frac{3 e}{\zeta} \right) + \frac{(12 + 2\zeta) M_t}{3(1 - \eta)n} \log \left( \frac{3}{\zeta} \right)$.

(c) If Assumptions 2 and 4 hold, then for all $\eta, \zeta > 0$, with probability at least $1 - \zeta$, the primal excess population risk satisfies

$R(A_w(S)) - \frac{1}{1 - \eta} \inf_{w \in W} R(w) \leq \sqrt{\left( \frac{1 + L/\rho \gamma^2 (1 + 64 n \log \left( \frac{6 \eta}{\zeta} \right))}{2 \left( 1 - \eta \right)^2 n} \right)} \log \left( \frac{6}{\zeta} \right) + \frac{50 \sqrt{2} (1 + e + L/\rho) G \gamma \log(n)}{1 - \eta} \log \left( \frac{6 e}{\zeta} \right) + \frac{(24 + 4\zeta) M_t}{3(1 - \eta)n} \log \left( \frac{6}{\zeta} \right) + \frac{1}{1 - \eta} \Delta_S^* (A_w(S), A_v(S))$.

(d) If Assumptions 2 and 5 hold, then for all $\eta, \zeta > 0$, with probability at least $1 - \zeta$, the strong primal dual
population risk satisfies

\[ \Delta^* \left( A_w(S), A_v(S) \right) \leq \frac{100 \sqrt{2} e (1 + \epsilon) (1 + L / \rho) G \gamma \log(n)}{1 - \epsilon} \log \left( \frac{e}{\zeta} \right) + \frac{144 e (1 + \epsilon) G^2}{\rho (1 - \epsilon) n} \log \left( \frac{e}{\zeta} \right) + \frac{8 e (1 + \epsilon) M_t}{n (1 - \epsilon)} \log \left( \frac{e}{\zeta} \right) + \left( \frac{e^2}{1 - \epsilon} \log \left( \frac{e}{\zeta} \right) + 1 \right) \Delta^*_S \left( A_w(S), A_v(S) \right). \]

Remark 5. For part (a), the plain generalization error is essentially analyzed via uniform stability, defined as the upper bound of \( \ell \left( A_w(S), A_v(S); z \right) - \ell \left( A_w(S'), A_v(S'); z \right) \). If the loss function \( \ell \left( \cdot, \cdot ; \cdot \right) \) is G-Lipschitz (Assumption 3), \( \gamma \)-argument stability derives \( G \gamma \)-uniform stability (details can be found in (72) in Appendix A.3). Then the proof of part (a) is completed by the uniform stability of model \( (A_w(S), A_v(S)) \). For parts (b), (c), and (d), argument stability is applied to get the claimed results. The proof can be found in Appendix A.3.

We give the bound of \( \Delta^*_S \left( A_w(S), A_v(S) \right) \) in the following and then discuss the results given in Theorem 3.

Lemma 2. If Assumptions 7 and 2 hold. Taking \( \sigma \) given in Theorem 1 and \( \eta = \frac{\sigma}{\eta} \), then with probability at least \( 1 - \zeta \) for \( \zeta \in (\exp(-\frac{E}{4}), 1) \), the strong primal dual empirical risk of the output of DP-GDA: \( A(S) = (\overline{w}_T, \overline{v}_T) \) satisfies

\[ \Delta^*_S \left( \overline{w}_T, \overline{v}_T \right) \leq \frac{G^2 \log(e T)}{\rho T} + \frac{c G \left( g_w + g_v \right) \sqrt{\bar{T}p \log(1/\delta)}}{\eta c} p^*_\zeta + c G^2 \log(e T) \left( \frac{p \log(1/\delta)}{\rho n^2 e^2} \right) p^*_\zeta + 2 \sqrt{\rho T n e p^*_\zeta} \left( \frac{p \log(1/\delta)}{\rho n^2 e^2} \right) p^*_\zeta, \]

for some constant \( c \), where \( p^*_\zeta, g_w, g_v \) are defined as in Theorem 2.

The proof of Lemma 2 is a vital part of Theorem 2. For clarity, we give a brief sketch in Appendix A.4.

Given the strong PD empirical risk \( \Delta^*_S \left( \overline{w}_T, \overline{v}_T \right) \) and the argument stability parameter \( \gamma \) of the output of DP-GDA: \( (\overline{w}_T, \overline{v}_T) \), we now give some discussions of Theorem 3 in Remark 6.

Remark 6. Part (a) connects the argument stability with the plain generalization error, for the output of Algorithm 7 if taking \( T = \mathcal{O}(n^{2/3}) \), we have \( \gamma = \mathcal{O} \left( \frac{n^{2/3}}{\log(n)} \right) \) as discussed in Remark 2. Then plugging this result back into the plain generalization error, with high probability, we can bound \( L \left( \overline{w}_T, \overline{v}_T \right) \) by

\[ \frac{1}{1 - \epsilon} \mathcal{O} \left( L_S \left( \overline{w}_T, \overline{v}_T \right) + \frac{p^{1/3} \log(n)}{n^{2/3} \epsilon} \right). \]

For a well trained model (with \( n \) large enough), the empirical risk \( L_S \left( \overline{w}_T, \overline{v}_T \right) \) can be relatively small \cite{levere2013}. As a result, if \( L_S \left( \overline{w}_T, \overline{v}_T \right) = \mathcal{O} \left( 1 / n^{1/3} \right) \), the plain generalization error along with the plain population risk can be bounded by \( \mathcal{O} \left( \frac{n^3}{\rho T} \right) \) if \( \log(\cdot) \) terms are omitted.

Part (b) connects the argument stability with the primal generalization error. Like discussed above, taking \( \gamma \) when \( T = \mathcal{O}(1/n^{2/3}) \), \( R \left( \overline{w}_T, \overline{v}_T \right) \) can be bounded by

\[ \frac{1}{1 - \epsilon} \mathcal{O} \left( R_S \left( \overline{w}_T \right) + \frac{p^{1/3} \log(n)}{n^{2/3} \epsilon} \right). \]

with high probability. Thus, for well trained model, the primal generalization error along with the primal population risk can be bounded by \( \mathcal{O} \left( \frac{n^{3/4}}{n^{1/3} \rho T} \right) \).

Part (c) connects the argument stability with the primal excess population risk. Here, we still taking \( T = \mathcal{O}(1/n^{3/4}) \). Under this circumstance, the strong PD empirical risk of \( \left( \overline{w}_T, \overline{v}_T \right) \) can be bounded by

\[ \mathcal{O} \left( \frac{p^{1/3}}{n^{2/3} \epsilon} + 1 \right). \]

As a result, the primal excess population risk can be bounded by

\[ \frac{1}{1 - \epsilon} \mathcal{O} \left( \frac{p^{1/3}}{n^{2/3} \epsilon} + \frac{p^{1/3}}{n^{2/3} \epsilon} + 1 + \inf_{w \in \mathcal{W}} R(w) \right). \]

If \( \inf_{w \in \mathcal{W}} R(w) \) is smaller than the maximum value of the other three terms, the primal population risk can be bounded by

\[ \mathcal{O} \left( \max \left\{ \frac{p^{1/3}}{n^{2/3} \epsilon} + \frac{p^{1/3}}{n^{2/3} \epsilon} + 1 \right\} \right). \]

Part (d) connects the argument stability with the strong PD population risk. Like discussed above, if we take \( T = \mathcal{O}(1/n^{2/3}) \), the strong PD empirical risk of \( \left( \overline{w}_T, \overline{v}_T \right) \) shares the same property as in (7), and the strong PD population risk can be bounded by

\[ \mathcal{O} \left( \max \left\{ \frac{p^{1/3}}{n^{2/3} \epsilon} + \frac{p^{1/3}}{n^{2/3} \epsilon} + 1 \right\} \right). \]

Remark 7. Here, we discuss coefficient \( \epsilon \) in Theorem 3. We first explain why \( \epsilon \) exists. The existence of \( \epsilon \) is because when decomposing term \( \sqrt{L(w, v)/n} \), inequality \( \sqrt{ab} \leq a + b/\epsilon \) was applied. Then we have

\[ \sqrt{L(w, v)/n} \leq \ell L(w, v) + 1/(\epsilon n). \]

In this way, we decouple \( n \) from the square root, in order to get sharper bounds when connecting stability with the generalization error (the improvement is from \( \mathcal{O}(\sqrt{1/n}) \) to \( \mathcal{O}(1/n) \)), especially when the model is well behaved, \( L(w, v) \)

3We omit other terms here (such as \( \log(1/\zeta) \) and \( M_t \)), details can be found in the Appendix.
is a small value. Besides, when it comes to analyzing sharp generalization error, $\iota$ commonly appears. For clarity, in the following, we represent the population risk and the empirical risk by $P f$ and $P_{n, f}$, respectively, like in (Bartlett, Bousquet, and Mendelson 2005). Bartlett, Bousquet, and Mendelson 2005 proposes the generalization error like $P f \leq \mathcal{O}(1 + \iota) P_{n, f} + r^*$ + $\log(1/\iota)$. Klochkov and Zhivotovskiy 2021 proposes the generalization error like $P f \leq \mathcal{O}(1 + \iota) P_{n, f} + r^*$ + $\log(1/\iota)$. These results are similar to ours by rearrangement, differences are caused by choosing different $\iota$. Results in the similar form include (Catoni 2007), (Lever, Laviolette, and Shawe-Taylor 2013), (Yang, Sun, and Roy 2019), to mention but a few. When the machine learning model is well trained and the empirical risk is small, generalization error of this form is better (Bartlett, Bousquet, and Mendelson 2005, Lever, Laviolette, and Shawe-Taylor 2013, Yang, Sun, and Roy 2019, Klochkov and Zhivotovskiy 2021, Cortes, Mohri, and Suresh 2021).

According to the property of the weak PD population risk, we can directly get the following corollary via Theorem 3.

**Corollary 1.** With argument stability parameter $\gamma$,

(a) Under the condition given in Theorem 3 part (d), the strong PD generalization error satisfies

$$\Delta^*(A_w(S), A_v(S)) - \Delta^*_{\mathcal{L}}(A_w(S), A_v(S))$$

\[\leq \frac{100 \sqrt{2e}(1 + \iota)(1 + L/\rho)G\gamma \log(n)}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{144e(1 + \iota)G^2}{\rho(1 - \iota)n} \log \left(\frac{e}{\zeta}\right) + \frac{8e(1 + \iota)M_t}{n(1 - \iota)} \log \left(\frac{e}{\zeta}\right) + \frac{e\iota}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{1}{\Delta^*_{\mathcal{L}}(A_w(S), A_v(S))}.\]

(b) Under the condition given in Theorem 3 part (d), the weak primal dual population risk satisfies

$$\Delta^w(A_w(S), A_v(S))$$

\[\leq \frac{100 \sqrt{2e}(1 + \iota)(1 + L/\rho)G\gamma \log(n)}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{144e(1 + \iota)G^2}{\rho(1 - \iota)n} \log \left(\frac{e}{\zeta}\right) + \frac{8e(1 + \iota)M_t}{n(1 - \iota)} \log \left(\frac{e}{\zeta}\right) + \frac{e\iota}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{1}{\Delta^*_{\mathcal{L}}(A_w(S), A_v(S))}.\]

(c) Under the condition given in Theorem 3 part (d), the weak PD generalization error satisfies

$$\Delta^w(A_w(S), A_v(S)) - \Delta^w_{\mathcal{L}}(A_w(S), A_v(S))$$

\[\leq \frac{100 \sqrt{2e}(1 + \iota)(1 + L/\rho)G\gamma \log(n)}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{144e(1 + \iota)G^2}{\rho(1 - \iota)n} \log \left(\frac{e}{\zeta}\right) + \frac{8e(1 + \iota)M_t}{n(1 - \iota)} \log \left(\frac{e}{\zeta}\right) + \frac{e\iota}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{1}{\Delta^*_{\mathcal{L}}(A_w(S), A_v(S))}.\]

Corollary 1 can be easily extended from Theorem 3 part (d). For clarity, we give proof sketches in Appendix A.5. Meanwhile, the strong and weak PD generalization errors and the weak PD population risk share similar properties with the strong PD population risk given in Theorem 3 part (d), as discussed in Remark 6.

**Remark 8.** By the discussions given in Remark 6, we find that the bottleneck of the generalization bounds is the injected random noise, rather than the analysis approach itself. The reason is that we apply novel decomposition methods (motivated by (Klochkov and Zhivotovskiy 2021)) and overcome the $O(1/\sqrt{n})$ terms when connecting the stability with the generalization error. However, when it comes to DP paradigm, when analyzing $\gamma$, there exists term $\sqrt{T/n}$.

$$\mathcal{O}(\sqrt{T/n})$$

in which term $\sqrt{T/n}$ is derived from the standard deviation $\sigma$ of the random noise and term $\sqrt{1/T}$ is derived from the optimization error. Together with the discussions given before, in the minimax problem, it is hard to eliminate term $\|b\|_1$ because $w$ differs when $v$ changes. So the best result is $\mathcal{O}(1/\sqrt{n})$, under the setting of gradient perturbation concentrated by this paper, and this may give inspirations to other researchers on how to get better generalization performance in the DP-minimax condition.

**Comparisons with Related Work**

In this section, we compare our given bounds with previous related work. The generalization bounds under corresponding assumptions are listed in detail in Table 1, in which $\rho, G, L$ represents $\rho$-SC-SC, $G$-Lipschitz, and $L$-smooth, respectively. Considering there is no existing work analyzing the theoretical bounds for the general DP-minimax problem, so we only give our results in Table 1.

**Non-DP General Minimax Setting**

For the general minimax problem, DP has not been applied to the best of our knowledge so we compare our results with previous non-DP results (Farnia and Ozdaglar 2021, Lei et al. 2021, Zhang et al. 2021). Among them, (Zhang et al. 2021) focuses on ESP and (Lei et al. 2021) focuses on SGDA and AGDA, so the only existed result for GDA is given in (Farnia and Ozdaglar 2021), it is an $O(1/n)$ primal generalization error for GDA in expectation.

**DP-Minimax Settings**

For DP-minimax settings, to the best of our knowledge, the theoretical results are only explicitly given for DP-AUC maximization: Wang et al. 2021b gives the expectation excess population risk bounds for DP-AUC maximization problems under output perturbation and objective perturbation methods. The results

\[4\text{We pay our attentions to the balance between } T \text{ and } n \text{ here and omit parameters } p, \epsilon.\]
Table 1: Utility bounds of our proposed DP-GDA method.

are of the orders \( O\left( \max \left\{ \frac{p^{1/3}/\sqrt{\epsilon}}{(n\epsilon)^{2/3}}, \frac{1}{\sqrt{n}} \right\} \right) \) and \( O\left( \max \left\{ \frac{p}{(n\epsilon)^{2}}, \frac{1}{\sqrt{n}} \right\} \right) \) for output and objective perturbations, respectively. Considering that it is hard to compare high probability bounds with expectation bounds, and the perturbation methods are different, we only list them here for comparisons. \( \text{[Huai et al. 2020]} \) \( \text{[Yang et al. 2021]} \) analyzes the high probability excess population risk for DP-AUC maximization problems under the pairwise learning paradigm, whose bounds are of the order \( O\left( \frac{p}{\sqrt{n\epsilon}} \right) \). In this paper, corresponding generalization measure is the plain population risk, so our result is better than previous ones, by an order of \( O\left( \frac{p^{1/4}/\sqrt{\epsilon}}{(n\epsilon)^{2/3}} \right) \), considering \( \epsilon \) is always set smaller than 1 for meaningful DP.

Conclusion

In this paper, we focus on the differential privacy of general minimax paradigm and propose DP-GDA. Except for the privacy guarantees, we analyze the stability of DP-GDA and connect it with the generalization performance. Furthermore, we give corresponding bounds under different generalization measures and compare them with previous works on differentially private particular minimax models, theoretical results show that our generalization bounds are better. We believe that our analysis and discussions will give inspirations to DP-minimax generalization performance researches. In future work, we will attempt to relax the assumptions needed in this paper, and overcome challenges brought by the injected random noise, in order to give sharper generalization bounds for general DP-minimax paradigm.

References

Details of proofs

Recall that in DP-GDA, the training process is
\[
\begin{align*}
\mathbf{w}_{t+1} &= \mathbf{w}_t - \eta_t \left( \nabla_{\mathbf{w}} L_S(\mathbf{w}_t, \mathbf{v}_t) + b_w \right), \\
\mathbf{v}_{t+1} &= \mathbf{v}_t + \eta_t \left( \nabla_{\mathbf{v}} L_S(\mathbf{w}_t, \mathbf{v}_t) + b_v \right),
\end{align*}
\]
where \( b_w, b_v \sim \mathcal{N}(0, \sigma^2 I_p) \) and \( \sigma = \sqrt[4]{\frac{G}{T \log(1/\delta)}} \).

And the output is the average of iterates, defined as
\[
\tilde{\mathbf{w}}_T = \frac{1}{T} \sum_{t=1}^{T} \mathbf{w}_t, \quad \tilde{\mathbf{v}}_T = \frac{1}{T} \sum_{t=1}^{T} \mathbf{v}_t.
\]

Proof of Theorem 1

Before detailed proof, we first revisit the moments accountant method (Abadi et al. 2016).

**Definition 4.** [Privacy loss (Abadi et al. 2016)] For adjacent datasets \( D, D' \), mechanism \( M \) and an output \( o \in \mathbb{R} \), the privacy loss at \( o \) is defined as:
\[
c(o; M, D, D') = \log \left( \frac{\mathbb{P} [M(D) = o]}{\mathbb{P} [M(D') = o]} \right).
\]

**Definition 5.** [Moment (Abadi et al. 2016)] For given mechanism \( M \) and the privacy loss at output \( o \), the \( \lambda \)th moment is defined as:
\[
\alpha_M(\lambda; D, D') = \log \left( \mathbb{E}_{o \sim M(D)} \left[ \exp (\lambda c(o; M, D, D')) \right] \right),
\]
whose upper bound is defined as:
\[
\alpha_M(\lambda) = \max_{D, D'} \alpha_M(\lambda; D, D').
\]

**Lemma 3.** [Composability (Abadi et al. 2016)] Let \( \alpha_M(\lambda) \) defined as above and suppose \( M \) consists of several mechanisms \( M_1, \ldots, M_k \) and \( M_i \) relies on \( M_1, \ldots, M_{i-1} \). Then for any \( \lambda \):
\[
\alpha_M(\lambda) \leq \sum_{i=1}^{k} \alpha_{M_i}(\lambda).
\]

**Lemma 4.** [Tail Bound (Abadi et al. 2016)] Let \( \alpha_M(\lambda) \) defined as above, for any \( \epsilon > 0 \), \( M \) is \((\epsilon, \delta)\)-differential privacy if
\[
\delta = \min_{\lambda} \exp \left( \alpha_M(\lambda) - \lambda \epsilon \right).
\]

**Definition 6.** [Rényi Divergence (Bun and Steinke 2016)] Let \( P \) and \( Q \) be probability distributions, for \( \kappa \in (1, \infty) \), the Rényi Divergence of order \( \kappa \) between \( P \) and \( Q \) is defined as:
\[
D_{\kappa}(P||Q) = \frac{1}{\kappa - 1} \log \left( \mathbb{E}_{x \sim P} \left[ \left( \frac{P(x)}{Q(x)} \right)^{\kappa-1} \right] \right).
\]

**Lemma 5.** Let \( \mu, \nu \in \mathbb{R}^p \), \( \sigma \in \mathbb{R} \), and \( \kappa \in (1, \infty) \), then for Gaussian distribution \( \mathcal{N}(\cdot, \cdot) \), we have
\[
D_{\kappa} \left( \mathcal{N}(\mu, \sigma^2 I_p) \ || \mathcal{N}(\nu, \sigma^2 I_p) \right) = \frac{\kappa \| \mu - \nu \|^2}{2 \sigma^2}.
\]

Then, we give the detailed proof.

**Theorem 4.** If \( \ell(\cdot, \cdot, \cdot) \) satisfies Assumption 1 then for \( \epsilon, \delta > 0 \), DP-GDA is \((\epsilon, \delta)\)-DP if
\[
\sigma = \mathcal{O} \left( \frac{G \sqrt{T \log(1/\delta)}}{n \epsilon} \right).
\]

**Proof.** We first analyze parameter \( w \).

When updating \( w \) at iteration \( t \), the randomized mechanism \( M_t \) which may disclose privacy is
\[
M_t = \nabla_{\mathbf{w}} L_S(\mathbf{w}_t, \mathbf{v}_t) + b_w = \frac{1}{n} \sum_{i=1}^{n} \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, \mathbf{v}_t; z_i) + b_w.
\]

Denote probability distribution of \( M_t \) over adjacent datasets \( D, D' \) as \( P \) and \( Q \), respectively, we have
\[
P = \frac{1}{n} \sum_{i=1}^{n-1} \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, \mathbf{v}_t; z_i) + \frac{1}{n} \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, \mathbf{v}_t; z_n) + b_w,
\]
\[
Q = \frac{1}{n} \sum_{i=1}^{n-1} \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, \mathbf{v}_t; z_i) + \frac{1}{n} \nabla_{\mathbf{w}} \ell(\mathbf{w}_t, \mathbf{v}_t; z_n') + b_w,
\]
where we assume the single different data sample is the \( n^{th} \) one.

Noting that \( \bar{b}_w \sim \mathcal{N}(0, \sigma^2 I_p) \), we have

\[
P = \mathcal{N}\left( \frac{1}{n} \sum_{i=1}^{n-1} \nabla_w \ell(w_t, v_i; z_i) + \frac{1}{n} \nabla_w \ell(w_t, v_i; z_n), \sigma^2 I_p \right),
\]

\[
Q = \mathcal{N}\left( \frac{1}{n} \sum_{i=1}^{n-1} \nabla_w \ell(w_t, v_i; z_i) + \frac{1}{n} \nabla_w \ell(w_t, v_i; z'_n), \sigma^2 I_p \right).
\]

By Definition, we have

\[
\alpha_M(\lambda; D, D') = \log \left( \mathbb{E}_{v \sim P} \left[ \exp \left( \lambda \log \left( \frac{P}{Q} \right) \right) \right] \right) = \log \left( \mathbb{E}_{v \sim P} \left[ \left( \frac{P}{Q} \right)^\lambda \right] \right) = \lambda D + 1 (P \| Q),
\]

where the last equality holds because of Definition.

Via Lemma, we have

\[
\alpha_M(\lambda; D, D') = \lambda(\lambda + 1) \left( \frac{1}{n} \left( \nabla_w \ell(w_t, v_i; z_n) - \nabla_w \ell(w_t, v_i; z'_n) \right) \right) \leq 2G^2 \lambda(\lambda + 1) = \alpha_M(\lambda),
\]

where the inequality holds because \( \ell \) is \( G \)-Lipschitz and the last equality holds because of Definition.

Via Lemma, since there are \( T \) iterations, we have

\[
\alpha_M(\lambda) \leq \sum_{i=1}^{T} \alpha_M(\lambda) \leq \frac{4G^2 \lambda^2 T}{n^2 \sigma^2},
\]

where the last inequality holds because \( \lambda \in (1, \infty) \).

Taking \( \sigma = \frac{G \sqrt{T \log(1/\delta)}}{\epsilon} \), we can guarantee \( \alpha_M(\lambda) \leq \lambda \epsilon/2 \) and as a result, we have \( \delta \leq \exp(-\lambda \epsilon/2) \), which leads to \((\epsilon, \delta)\)-DP via Lemma.

The training process over parameter \( v \) is similar, so if \( b_v \sim \mathcal{N}(0, \sigma^2 I_p) \) with \( \sigma = \frac{G \sqrt{T \log(1/\delta)}}{\epsilon} \) is injected into the gradient when updating \( v \), then \((\epsilon, \delta)\)-DP can be guaranteed.

Moreover, as discussed in Section 4, the average operator does not violate differential privacy because of the Post-Processing property [Dwork and Roth 2014].

The proof is complete.

\[
\square
\]

**Proof of Theorem**

To get the stability bound, we further need the following lemma.

**Lemma 6.** [Yang et al. 2021] If Gaussian noise \( b \sim \mathcal{N}(0, \sigma^2 I_p) \), then for \( \zeta \in (\exp(-\frac{\epsilon}{\delta}), 1) \), with probability at least \( 1 - \zeta \)

\[
||b||_2 \leq \sigma \sqrt{p} \left( 1 + \left( \frac{8 \log(1/\zeta)}{\epsilon} \right)^{1/4} \right).
\]

Then, we start our proof.

**Theorem 5.** If Assumptions and hold. Then with \( \sigma \) given in Theorem and \( \eta_t = \frac{1}{\rho_t} \), the output of DP-GDA (Algorithm 1) \( A_i(S) = (\bar{w}_T, \bar{v}_T) \) is \( \gamma \)-argument stable with probability at least \( 1 - \zeta \) for \( \zeta \in (\exp(-\frac{\epsilon}{\delta}), 1) \), where

\[
\gamma = \frac{4G}{n\rho} + 2\sigma \sqrt{p} \log(eT) p_c + 4\sqrt{\log(eT)} \sqrt{\frac{G^2}{\rho^2 T} + \frac{\sigma^2 p}{\rho^2 T} p_c^2 + \frac{2G\sigma}{\rho T} p_c + \frac{(g_w + g_v) \sqrt{p_c}}{\rho \log(eT)} p_c,
\]

where \( p_c = 1 + \left( \frac{8 \log(2T/\zeta)}{\epsilon} \right)^{1/4} \), \( g_w = ||\bar{w}_T - \bar{w}_T||_2 \), and \( g_v = ||\bar{v}_T - \bar{v}_T||_2 \) for \( \bar{w}_T = \arg \min_{w \in W} L_S(w, \bar{w}_T) \), and \( \bar{v}_T = \arg \max_{v \in V} L_S(\bar{w}_T, v) \).

\footnote{This assumption is only for simplicity, the different data sample can be anyone in the dataset.}
Proof. We define the dataset adjacent to $S$ as $S^{(i)} = \{z_1, \cdots, z_{i-1}, z_i', z_{i+1}, \cdots, z_n\}$. At iteration $t$, $(w_t, v_t)$ is the output derived from $S$ and $(w_t^{(i)}, v_t^{(i)})$ derived from $S^{(i)}$.

Let $w_S^*, v_S^*$ be the Empirical Saddle Point (ESP) over dataset $S$ and $w_{S^{(i)}}^*, v_{S^{(i)}}^*$ be the ESP over dataset $S^{(i)}$. Then we have

$$L_S (w_S^{*}, v_S^{*}) - L_S (w_{S^{(i)}}^*, v_{S^{(i)}}^*)$$

$$= \frac{1}{n} \sum_{i=1}^{n} (\ell(w_S^{*}, v_S^{*}; z) - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z))$$

$$= \frac{1}{n} \left( \sum_{i=1, j \neq i}^{n} (\ell(w_S^{*}, v_S^{*}; z) - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z)) + \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i') - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i) \right)$$

$$+ \frac{1}{n} (\ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i) - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i)) - \frac{1}{n} (\ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i) - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i))$$

$$= L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*) - L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*)$$

$$+ \frac{1}{n} (\ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i) - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i)) + \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i') - \ell(w_{S^{(i)}}^*, v_{S^{(i)}}^*; z_i')$$

$$\leq L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*) - L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*) + \frac{2G}{n} \left( ||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \right)$$

$$= L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*) - L_{S^{(i)}} (w_{S^{(i)}}^*, v_{S^{(i)}}^*) + \frac{2G}{n} \left( ||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \right)$$

$$\leq -\frac{\rho}{2} \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right) \leq -\frac{\rho}{2} \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right) + \frac{2G}{n} \left( ||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \right),$$

where the first inequality holds because $\ell(\cdot, \cdot, \cdot)$ is $G$-Lipschitz, the second inequality holds because $L_{S^{(i)}}$ is $\rho$-SC-SC, $\nabla w L_{S^{(i)}} (w_{S^{(i)}}^*, \cdot) = 0$, and $\nabla v L_{S^{(i)}} (\cdot, v_{S^{(i)}}^*) = 0$.

Similarly, since $L_S$ is $\rho$-SC-SC, we have

$$L_S (w^{*}, v_S^{*}) - L_S (w_{S^{(i)}}^*, v_{S^{(i)}}^*) \geq \frac{\rho}{2} \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right).$$

Thus

$$\frac{\rho}{2} \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right) \leq -\frac{\rho}{2} \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right) + \frac{2G}{n} \left( ||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \right),$$

which derives

$$\rho \left( ||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2 \right) \leq \frac{2G}{n} \left( ||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \right) \leq \frac{2\sqrt{G}}{n} \sqrt{||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2},$$

where the last inequality holds because $a + b \leq \sqrt{2(a^2 + b^2)}$ for all $a, b > 0$.

Therefore, we have

$$\sqrt{||w_{S^{(i)}}^* - w_S^*||_2^2 + ||v_S^* - v_{S^{(i)}}^*||_2^2} \leq \frac{2\sqrt{G}}{n\rho}.$$

And

$$||w_{S^{(i)}}^* - w_S^*||_2 + ||v_S^* - v_{S^{(i)}}^*||_2 \leq \frac{4G}{n\rho}.$$  

(3)

Since the stability only depends on adjacent datasets, so we consider the noises injected to $S$ and $S^{(i)}$ are the same. As a
result,

\[ \|w^{(i)}_t - w_i\|_2 + \|v^{(i)}_t - v_i\|_2 \]

\[ = \|w^{(i)}_t - w^{*}_S\|_2 + \|w^{*}_S - w_{S(t)} - w_i\|_2 + \|v^{(i)}_t - v^{*}_{S(t)} - v_i\|_2 \]

\[ \leq \|w^{(i)}_t - w^{*}_S\|_2 + \|w^{*}_S - w_{S(t)}\|_2 + \|v^{(i)}_t - v^{*}_{S(t)}\|_2 + \|v^{*}_{S(t)} - v_i\|_2 \]

\[ \leq \frac{4G}{n\rho} + \|w^{(i)}_t - w^{*}_{S(t)}\|_2 + \|w^{*}_S - w_i\|_2 + \|v^{(i)}_t - v^{*}_{S(t)}\|_2 + \|v^{*}_{S(t)} - v_i\|_2 \]

\[ \leq \frac{4G}{n\rho} + \sqrt{2 \left( \|w^{(i)}_t - w^{*}_S\|_2^2 + \|v^{(i)}_t - v^{*}_{S(t)}\|_2^2 \right)} + \sqrt{2 \left( \|w^{*}_S - w_i\|_2^2 + \|v^{*}_S - v_i\|_2^2 \right)} \]

where the second inequality holds because of (3), the third inequality holds because \( a + b \leq \sqrt{2(a^2 + b^2)} \) for all \( a, b > 0 \), and the last inequality holds because both \( L_S \) and \( L_{S(t)} \) are \( \rho \)-SC-SC (as discussed in (2)).

Since terms \( L_{S(t)}(w^{(i)}_t, v^{*}_{S(t)}) - L_{S(t)}(w^{*}_{S(t)}, v^{(i)}_t) \) and \( L_S(w, v^*_S) - L_S(w^*_S, v_t) \) are both strong PD empirical risk, we bound them with the same measure for brevity:

\[ \|w^{(i)}_t - w_i\|_2 + \|v^{(i)}_t - v_i\|_2 \leq \frac{4G}{n\rho} + 4\sqrt{\frac{1}{\rho} \Delta S(w, v, t)}. \] (4)

Till iteration \( t \), noise is added to the model \( t \) times on both \( w \) and \( v \), so when it comes to the noisy version, the fluctuations caused by the injected noise lead (4) to:

\[ \|w^{(i)}_t - w_i\|_2 + \|v^{(i)}_t - v_i\|_2 \leq \frac{4G}{n\rho} + 4\sqrt{\frac{1}{\rho} \Delta S(w, v, t)} + \sum_{k=1}^{t} \eta_k \|b_w\|_2 + \sum_{k=1}^{t} \eta_k \|b_v\|_2. \] (5)

Now we bound the strong PD empirical risk \( \Delta S(w, v, t) \).

Firstly, we have

\[ \|w_{t+1} - w\|^2 = \|w_t - \eta_t (\nabla_w L_S(w, v_t) + b_w) - w\|^2 \]

\[ = \|w_t - w\|^2 + \eta^2_t \|\nabla_w L_S(w, v_t) + b_w\|^2 + 2\eta_t \langle w - w_t, \nabla_w L_S(w, v_t) + b_w \rangle \]

\[ \leq \|w_t - w\|^2 + \eta^2_t G^2 + \eta^2_t \|b_w\|^2 + 2\eta_t G \|b_w\|_2 + 2\eta_t \langle w - w_t, \nabla_w L_S(w, v_t) \rangle + 2\eta_t \langle w - w_t, b_w \rangle , \]

where the last inequality holds because of Cauchy-Schwartz inequality.

Note that \( L_S(\cdot, v_t) \) is \( \rho \)-strongly convex, we have

\[ L_S(w, v_t) - L_S(w, v_i) \geq \langle \nabla_w L_S(w, v_t), w - w_t \rangle + \frac{\rho}{2} \|w - w_t\|^2 . \]

So

\[ \|w_{t+1} - w\|^2 \leq (1 - \eta_t \rho) \|w - w_t\|^2 + \eta^2_t G^2 + \eta^2_t \|b_w\|^2 + 2\eta_t G \|b_w\|_2 + 2\eta_t \langle w - w_t, b_w \rangle + 2\eta_t \langle w - w_t, v_t \rangle . \]

Taking \( \eta_t = \frac{1}{\rho(t + \varphi)} \), we have

\[ \frac{2}{\rho(t + \varphi)} (L_S(w_t, v_t) - L_S(w, v_t)) \leq \left( 1 - \frac{1}{t + \varphi} \right) \|w - w_t\|^2 - \|w_{t+1} - w\|^2 + \frac{2}{\rho(t + \varphi)} \|w - w_t, b_w\| \]

\[ + \left( \frac{1}{\rho(t + \varphi)} \right)^2 G^2 + \left( \frac{1}{\rho(t + \varphi)} \right)^2 \|b_w\|^2 + 2 \left( \frac{1}{\rho(t + \varphi)} \right)^2 G \|b_w\|_2 . \]

Multiplying both sides by \( t + \varphi \), we have

\[ \frac{2}{\rho} (L_S(w_t, v_t) - L_S(w, v_t)) \leq (t + \varphi - 1) \|w - w_t\|^2 - \|w_{t+1} - w\|^2 + \frac{2}{\rho} \langle w - w_t, b_w \rangle \]

\[ + \frac{G^2}{\rho^2(t + \varphi)} + \frac{1}{\rho^2(t + \varphi)} \|b_w\|^2 + \frac{2G}{\rho^2(t + \varphi)} \|b_w\|_2 . \]

Since \( \sum_{t=1}^{T} \frac{1}{t} \leq \log(eT) \), by summing over \( T \) iterations, the following inequality holds

\[ \sum_{t=1}^{T} (L_S(w_t, v_t) - L_S(w, v_t)) \leq \frac{n\rho}{2} \|w - w_t\|^2 + \sum_{t=1}^{T} \langle w - w_t, b_w \rangle + \frac{G^2 \log(eT)}{2\rho} + \frac{\log(eT)}{2\rho} \|b_w\|^2 + \frac{G \log(eT)}{\rho} \|b_w\|_2 . \]
For bounded $\mathcal{W}$ (i.e. $\|w - w\|_2 \leq M_0$ for all $w, w'$), we have:

$$
\sum_{t=1}^{T} (L_S(w_t, v_t) - L_S(w_t, v_t)) \leq \frac{\rho^2}{2} M_0^2 + \sum_{t=1}^{T} \langle w - w_t, b_w \rangle + \frac{G^2 \log(eT)}{2\rho} + \frac{\log(eT)}{2\rho} \|b_w\|_2^2 + \frac{G \log(eT)}{\rho} \|b_w\|_2.
$$

With the concavity of $L_S(w, \cdot)$, we have $TL_S(\nu_T) \geq \sum_{t=1}^{T} L_S(v_t)$, and noting that the inequality holds for any $w$, thus for $\nu^* = \arg \min_{w \in \mathcal{W}} L_S(\nu, \nu_T)$

$$
\sum_{t=1}^{T} L_S(w_t, v_t) - T \inf_{w \in \mathcal{W}} L_S(w, \nu_T) \leq \frac{\rho^2}{2} M_0^2 + \sum_{t=1}^{T} \langle \nu^* - w_t, b_w \rangle + \frac{G^2 \log(eT)}{2\rho} + \frac{\log(eT)}{2\rho} \|b_w\|_2^2 + \frac{G \log(eT)}{\rho} \|b_w\|_2,
$$

which implies

$$
\frac{1}{T} \sum_{t=1}^{T} L_S(w_t, v_t) - \inf_{w \in \mathcal{W}} L_S(w, \nu_T) \leq \frac{\rho^2}{2T} M_0^2 + \langle \nu^* - \nu_T, b_w \rangle + \frac{G^2 \log(eT)}{2\rho T} + \frac{\log(eT)}{2\rho T} \|b_w\|_2^2 + \frac{G \log(eT)}{\rho T} \|b_w\|_2. \tag{6}
$$

Similarly, with bounded $V$ (i.e. $\|v - v\|_2 \leq M_V$ for all $v, v'$), and denoting $\nu^* = \arg \max_{v \in \mathcal{V}} L_S(\nu_T, v)$, we have

$$
\sup_{v \in \mathcal{V}} L_S(\nu_T, v) - T \inf_{v \in \mathcal{V}} L_S(\nu_T, \nu_T) \leq \frac{\rho^2}{2T} M_V^2 + \langle \nu^* - \nu_T, b_v \rangle + \frac{G^2 \log(eT)}{2\rho T} + \frac{\log(eT)}{2\rho T} \|b_v\|_2^2 + \frac{G \log(eT)}{\rho T} \|b_v\|_2. \tag{7}
$$

Combining inequalities (6) and (7) together, with Cauchy-Schwartz inequality, we have

$$
\triangle_{\nu_T}(\nu_T, \nu_T) = \sup_{v \in \mathcal{V}} L_S(\nu_T, v) - \inf_{v \in \mathcal{V}} L_S(\nu_T, \nu_T) \leq \frac{\rho^2}{2T} (M_0^2 + M_V^2) + \frac{G^2 \log(eT)}{\rho T} + \frac{\log(eT)}{\rho T} \|b_w\|_2^2 + \frac{G \log(eT)}{\rho T} \|b_w\|_2^2 + g_w \|b_w\|_2 + g_v \|b_v\|_2,
$$

where $g_w = \|\nu^* - \nu_T\|_2$ and $g_v = \|\nu^* - \nu_T\|_2$.

Noting that this empirical risk bound holds for all datasets (no matter $S$ or $S(i)$, so (4) holds.

Taking this result back to (3), if taking $\varphi = 0$, for the average iterates, we have

$$
\|\bar{w}_T - \nu_T\|_2 + \|\bar{v}_T - \nu_T\|_2
\leq \frac{4G}{n\rho} + \frac{4}{\rho} \sqrt{\triangle_{\nu_T}(\nu_T, \nu_T)} + \frac{1}{T} \sum_{t=1}^{T} \eta_t (\|b_w\|_2 + \|b_v\|_2)
\leq \frac{4G}{n\rho} + \frac{\log(eT)}{T} (\|b_w\|_2 + \|b_v\|_2)
$$

$$
+ 4 \sqrt{\frac{G^2 \log(eT)}{\rho \rho T} + \frac{\log(eT)}{2\rho T} (\|b_w\|_2^2 + \|b_v\|_2^2) + \frac{G \log(eT)}{\rho T} (\|b_w\|_2 + \|b_v\|_2) + \frac{g_w \|b_w\|_2 + g_v \|b_v\|_2}{\rho}}.
$$

So, GDA is $\gamma$-argument stability where

$$
\gamma = 4 \sqrt{\frac{G^2 \log(eT)}{\rho \rho T} + \frac{\log(eT)}{2\rho T} (\|b_w\|_2^2 + \|b_v\|_2^2) + \frac{G \log(eT)}{\rho T} (\|b_w\|_2 + \|b_v\|_2) + \frac{g_w \|b_w\|_2 + g_v \|b_v\|_2}{\rho}} + \frac{4G}{np} + \frac{\log(eT)}{T} (\|b_w\|_2 + \|b_v\|_2).
$$

Noting that $b_w, b_v$ mentioned in (10) are derived from $T$ iterations, then via Lemma 5 for $\zeta \in (\exp(-\frac{\rho}{G}), 1)$ and $p_\zeta = 1 + \left(\frac{8 \log(GT/\rho)}{\rho}\right)^{1/4}$, with probability at least $1 - \zeta$, we have

$$
\gamma \leq 4 \sqrt{\frac{G^2 \log(eT)}{\rho \rho T} + \frac{\sigma^2 \log(eT)}{\rho T} p_\zeta^2 + \frac{2G \sqrt{\rho} \log(eT)}{\rho^2 T} p_\zeta} + \frac{(g_w + g_v) \sigma \sqrt{\rho}}{\rho} p_\zeta + \frac{4G}{np} + \frac{2\sqrt{\rho} \log(eT)}{T} p_\zeta,
$$

where the $\log(\cdot)$ term in $p_\zeta$ depends on probability over $T$ iterations and parameters $w, v$, which completes the proof. 

\qed
Proof of Theorem 3

Before the detailed proof, we first introduce the following lemmas.

**Lemma 7. ([Bousquet, Klochkov, and Zhivotovskiy 2020])** Let $S = \{z_1, \ldots, z_n\}$ be a set of independent random variables each taking values in $\mathcal{Z}$ and $M > 0$. Define $S \setminus \{z_i\} = \{z_1, \ldots, z_{i-1}, z_{i+1}, \ldots, z_n\}$. Let $g_1, \ldots, g_n$ be some functions $g_i : Z^n \rightarrow \mathbb{R}$ such that the following inequalities hold for any $i \in [1, n]$:

- $E_{S \setminus \{z_i\}}[g_i(S)] \leq M$ almost surely;
- $E_{z_i}[g_i(S)] = 0$ almost surely;
- for any $j = 1, \ldots, n$ ($j \neq i$) and $z'_j \in \mathcal{Z}$
  \[ g_i(S) - g_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, z_n) \leq \beta. \]

Then for any $\tau \geq 2$
\[ \left\| \sum_{i=1}^{n} g_i(S) \right\|_\tau \leq 12\sqrt{\tau n}\beta[\log(n)] + 4M\sqrt{\tau n}. \]

**Lemma 8. ([Bousquet, Klochkov, and Zhivotovskiy 2020])** For some $a, b > 0$ and any $\tau \geq 2$, $X$ is a random variable satisfies
\[ \|X\|_\tau \leq \sqrt{\tau a + \tau b}. \]

Then for any $\zeta \in (0, 1)$, with probability at least $1 - \zeta$
\[ |X| \leq e \left( a \sqrt{\log \left( \frac{e}{\zeta} \right)} + b \log \left( \frac{e}{\zeta} \right) \right). \]

**Lemma 9. ([Boucheron, Lugosi, and Massart 2013])** Let $z_1, \ldots, z_n$ be i.i.d random variables and assume that $E[z_i] = \mu$. Suppose $|z_i| < c$ for any $i$. Then for any $\zeta \in (0, 1)$, with probability at least $1 - \zeta$
\[ \left| \frac{1}{n} \sum_{i=1}^{n} z_i - \mu \right| \leq \sqrt{\frac{2\sigma^2 \log(1/\zeta)}{n}} + \frac{2c \log(1/\zeta)}{3n}, \]

where $\sigma^2$ is the variance of $z_i$.

**Lemma 10. ([Klochkov and Zhivotovskiy 2021])** If function $f : \mathcal{Z} \rightarrow [0, +\infty)$ is $(a, b)$-weakly self-bounded, corresponding $f_i(Z^n) \geq f(Z^n)$ for $i = 1, \ldots, n$ and any $Z^n \in \mathcal{Z}^n$, and $z_1, \ldots, z_n$ are independent random variables. Then, for any $t > 0$
\[ P \left( E[f(z_1, \ldots, z_n)] \geq f(z_1, \ldots, z_n) + t \right) \leq \exp \left( - \frac{t^2}{2aE[f(z_1, \ldots, z_n)] + 2b} \right). \]

**Lemma 11. ([Zhang et al. 2021])** Assume $f : \mathcal{W} \times \mathcal{V} \rightarrow \mathbb{R}$ is $\rho$-strongly-convex-strongly-concave and $L$-smooth. Defining $w^*(v) = \arg\min_{w \in \mathcal{W}} f(w, v)$ for any $v$, and $v^*(w) = \arg\max_{v \in \mathcal{V}} f(w, v)$ for any $w$. Then for any $w, w' \in \mathcal{W}$ and $v, v' \in \mathcal{V}$ there holds that
\[ \|w^*(v) - w^*(v')\|_2 \leq \frac{L}{\rho}\|v - v'\|_2, \quad \|v^*(w) - v^*(w')\|_2 \leq \frac{L}{\rho}\|w - w'\|_2. \]

**Lemma 12. ([Boucheron, Lugosi, and Massart 2013])** If $g_1, \ldots, g_n$ are i.i.d, zero mean and $|g_i| \leq M$ almost surely, then for any $\tau \geq 2$
\[ \left\| \sum_{i=1}^{n} g_i \right\|_\tau \leq 6 \sqrt{\left( \sum_{i=1}^{n} E[g_i^2] \right)} \tau + 4\tau M. \]

Besides, we need the following definition.

**Definition 7** (Weakly Self-Bounded Function). For all $Z^n \in \mathcal{Z}^n$, function $f : \mathcal{Z} \rightarrow [0, +\infty)$ is $(a, b)$-weakly self-bounded $(a, b > 0)$ if there exists $f_i : \mathcal{Z}^n \rightarrow [0, +\infty)$ that satisfies
\[ \sum_{i=1}^{n} (f(Z^n) - f_i(Z^n))^2 \leq a f(Z^n) + b. \]

Then, we recall Theorem 3 and start our proof.
Theorem 6. With argument stability parameter $\gamma$.
(a) If Assumptions $2$ and $4$ hold, then for all $\iota, \zeta > 0$, with probability at least $1 - \zeta$, the plain generalization error satisfies
$$L(A_w(S), A_v(S)) = \frac{1}{1 - \iota} L_S(A_w(S), A_v(S))$$
$$\leq \sqrt{\left(\frac{G^2 \gamma^2 + 64G^2 n^2 \log (3/\zeta)}{2(1 - \iota)^2 n}\right) \log \left(\frac{3}{\zeta}\right) + \frac{50\sqrt{2} e G \gamma \log(n)}{1 - \iota} \log \left(\frac{3e}{\zeta}\right) + \frac{(12 + 2\iota) M_{\ell}}{3(1 - \iota)n} \log \left(\frac{3}{\zeta}\right)}.$$

(b) If Assumptions $2, 3, 4, 5$ and $5$ hold, then for all $\iota, \zeta > 0$, with probability at least $1 - \zeta$, the primal generalization error satisfies
$$R(A_w(S)) = \frac{1}{1 - \iota} R_{\iota}(A_w(S))$$
$$\leq \sqrt{\left(\frac{(1 + L/\rho)^2 G^2 \gamma^2 (1 + 64n \log (6/\zeta))}{2(1 - \iota)^2 n}\right) \log \left(\frac{6}{\zeta}\right) + \frac{50\sqrt{2} (1 + e + L/\rho) G \gamma \log(n)}{1 - \iota} \log \left(\frac{6e}{\zeta}\right) + \frac{(24 + 4\iota) M_{\ell}}{3(1 - \iota)n} \log \left(\frac{6}{\zeta}\right) + \frac{1}{1 - \iota} \Delta_S^* A_w(S), A_v(S))}.$$

(c) If Assumptions $2, 3, 4$ and $5$ hold, then for all $\iota, \zeta > 0$, with probability at least $1 - \zeta$, the primal excess population risk satisfies
$$\Delta^* A_w(S), A_v(S))$$
$$\leq \frac{100\sqrt{2} e (1 + \iota)(1 + L/\rho) G \gamma \log(n)}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{144e (1 + \iota) G^2}{\rho (1 - \iota)n} \log \left(\frac{e}{\zeta}\right) + \frac{8e (1 + \iota) M_{\ell}}{n(1 - \iota)} \log \left(\frac{e}{\zeta}\right).$$

(d) If Assumptions $2, 3, 4$ and $5$ hold, then for all $\iota, \zeta > 0$, with probability at least $1 - \zeta$, the strong primal dual population risk satisfies
$$\Delta^* A_w(S), A_v(S))$$
$$\leq \frac{100\sqrt{2} e (1 + \iota)(1 + L/\rho) G \gamma \log(n)}{1 - \iota} \log \left(\frac{e}{\zeta}\right) + \frac{144e (1 + \iota) G^2}{\rho (1 - \iota)n} \log \left(\frac{e}{\zeta}\right) + \frac{8e (1 + \iota) M_{\ell}}{n(1 - \iota)} \log \left(\frac{e}{\zeta}\right).$$

Proof. Part (a): The plain generalization error.

Firstly, we have
$$nL(A_w(S), A_v(S)) - nL_S(A_w(S), A_v(S)) = \sum_{i=1}^n E_z \ell(A_w(S), A_v(S); z) - E_z^{(i)} \ell(A_w(S^{(i)}), A_v(S^{(i)}); z)$$
$$+ \sum_{i=1}^n E_z^{(i)} \ell(A_w(S^{(i)}), A_v(S^{(i)}); z) - E_z^{(i)} \ell(A_w(S^{(i)}), A_v(S^{(i)}); z_i)$$
$$+ \sum_{i=1}^n E_z^{(i)} \ell(A_w(S^{(i)}), A_v(S^{(i)}); z_i) - \sum_{i=1}^n \ell(A_w(S), A_v(S); z_i).$$

If algorithm $\mathcal{A}$ is $\gamma$-argument-stable, we have
$$\ell(A_w(S), A_v(S); z) - \ell(A_w(S'), A_v(S'); z)$$
$$= \ell(A_w(S), A_v(S); z) - \ell(A_w(S'), A_v(S); z) + \ell(A_w(S'), A_v(S); z) - \ell(A_w(S'), A_v(S'); z)$$
$$\leq G(\|A_w(S) - A_w(S')\|_2 + \|A_v(S) - A_v(S')\|_2)$$
$$\leq G\gamma,$$

where the first inequality holds because of the $G$-Lipschitz property and the last inequality holds because of the definition of $\gamma$-argument stability.
Defining $p_i(S) = \mathbb{E}_{z_i} \left[ \mathbb{E}_z \left[ \ell(A_w(S^{(i)}), A_v(S^{(i)}); z) \right] - \ell(A_w(S^{(i)}), A_v(S^{(i)}); z_i) \right]$, then

$$
nL(A_w(S), A_v(S)) - nL_S(A_w(S), A_v(S)) \leq 2Gn\gamma + \sum_{i=1}^n p_i(S). \tag{13}$$

Furthermore, we define $q_i(S) = p_i(S) - \mathbb{E}_{S \setminus \{z_i\}}[p_i(S)]$. It is easy to follow that $\mathbb{E}_{S \setminus \{z_i\}}[q_i(S)] = 0$ and $\mathbb{E}_z[q_i(S)] = \mathbb{E}_{z_i}[p_i(S)] - \mathbb{E}_{z_i, S \setminus \{z_i\}}[p_i(S)] = 0$. For any $j, j', n (j \neq i)$ and $z'_j \in \mathbb{Z}$, we have

$$
q_i(S) - q_i(z_1, \cdots, z_{j-1}, z'_j, z_{j+1}, \cdots, n) = p_i(S) - p_i(z_1, \cdots, z_{j-1}, z'_j, z_{j+1}, \cdots, n)
+ \mathbb{E}_{S \setminus \{z_i\}}[p_i(z_1, \cdots, z_{j-1}, z'_j, z_{j+1}, \cdots, n)] - \mathbb{E}_{S \setminus \{z_i\}}[p_i(S)]
\leq 4G\gamma,
$$

where the last inequality holds because of (12).

Then, via Lemma 7, we have

$$
\left\| \sum_{i=1}^n q_i(S) \right\|_\tau \leq 48\sqrt{2G\tau}n\gamma[\log(n)]. \tag{14}
$$

By the definition of $p_i(S)$ and $q_i(S)$, we have

$$
\sum_{i=1}^n (q_i(S) - p_i(S)) = -\sum_{i=1}^n \mathbb{E}_{S \setminus \{z_i\}}[p_i(S)]
= -\left( n\mathbb{E}_S L(A_w(S'), A_v(S')) - n\mathbb{E}_S L(A_w(S'), A_v(S')) \right)
= \left( n\mathbb{E}_S L(A_w(S), A_v(S)) - n\mathbb{E}_S L(A_w(S'), A_v(S')) \right), \tag{15}
$$

where the last equality holds because of the i.i.d property, i.e. $\mathbb{E}_S L(A_w(S), A_v(S')) = \mathbb{E}_S L(A_w(S), A_v(S))$.

Combining (13), (14), and (15) together, for $\tau \geq 2$, we have

$$
\left\| nL(A_w(S), A_v(S)) - nL_S(A_w(S), A_v(S)) \right\|_\tau
\leq \left\| nL(A_w(S), A_v(S)) - nL_S(A_w(S), A_v(S)) - \sum_{i=1}^n p_i(S) \right\|_\tau
+ \sum_{i=1}^n p_i(S) - \left( n\mathbb{E}_S L(A_w(S), A_v(S)) - n\mathbb{E}_S L(A_w(S'), A_v(S')) \right)
= \left\| nL(A_w(S), A_v(S)) - nL_S(A_w(S), A_v(S)) - \sum_{i=1}^n p_i(S) \right\|_\tau
+ \left\| \sum_{i=1}^n q_i(S) \right\|_\tau
\leq 2Gn\gamma + 48\sqrt{2G\tau}n\gamma[\log(n)]
\leq 50\sqrt{2G\tau}n\gamma[\log(n)].
$$

Via Lemma 8 with probability at least $1 - \zeta$, we have

$$
L(A_w(S), A_v(S)) - L_S(A_w(S), A_v(S))
\leq \left\| \mathbb{E}_S L(A_w(S'), A_v(S')) - \mathbb{E}_S L(A_w(S), A_v(S)) \right\|_\tau
+ 50\sqrt{2eG\gamma}[\log(n)] \log \left( \frac{e}{\zeta} \right). \tag{16}
$$

Now we bound term $\mathbb{E}_S L(A_w(S'), A_v(S')) - \mathbb{E}_S L(A_w(S), A_v(S))$. First, we consider $\mathbb{E}_S \ell(A_w(S'), A_v(S'); z)$.

By Jensen’s inequality, we have

$$
\mathbb{E}_{z_i} \left[ (\mathbb{E}_S \ell(A_w(S'), A_v(S'); z_i))^2 \right] \leq \mathbb{E}_{z_i} \left[ (\ell(A_w(S'), A_v(S'); z_i))^2 \right]
= \mathbb{E}_z [\mathbb{E}_S [\ell(A_w(S'), A_v(S'); z)^2]]
= \mathbb{E}_z \left[ (\ell(A_w(S), A_v(S); z))^2 \right].
$$
Noting that \( \mathbb{E} \left[ \mathbb{E}_z \left[ \ell(A_w(S'), A_v(S'); z) \right] \right] = \mathbb{E}_S L(A_w(S), A_v(S)) \) and via Lemma 9 if \( \ell(\cdot, \cdot) \) is bounded by \( M_f \), we have

\[
\left| \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] - \mathbb{E}_S \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right| \leq \frac{2 \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \log(1/\zeta)}{n} + \frac{2M_f \log(1/\zeta)}{3n}.
\]

(17)

Combining (16) and (17) together, with probability at least \( 1 - \zeta \), we have

\[
L(A_w(S), A_v(S)) - L_S(A_w(S), A_v(S)) \leq \frac{2 \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \log(2/\zeta)}{n} + \frac{2M_f \log(2/\zeta)}{3n} + 50\sqrt{2eG\gamma \log(n)} \log \left( \frac{2e}{\zeta} \right).
\]

(18)

Defining \( h = h(z_1, \cdots, z_n) = \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \) and \( h_i = h_i(z_1, \cdots, z_n) = \sup_{z_i \in Z} h(z_1, \cdots, z_n) \). We have

\[
\sum_{i=1}^n (q_i - q_i^*)^2 = \sum_{i=1}^n \left( \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] - \sup_{z_i \in Z} \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right)^2 \\
\leq G^2 \gamma^2 \sum_{i=1}^n \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \leq G^2 \gamma^2 \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] + G\gamma \left( \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right)^2 \\
\leq 8G^2 n \gamma^4 + 2G^4 n \gamma^4.
\]

where the first and second inequalities hold because of the definition of uniform stability, and the last inequality holds because \( (a + b)^2 \leq 2(a^2 + b^2) \) for \( a, b > 0 \).

Via Definition 7 it is easy to follow that \( h \) is \( (8G^2 n \gamma^2, 2G^4 n \gamma^4) \)-weakly self-bounded.

Via Lemma 10 with probability at least \( 1 - \zeta \), we have

\[
\mathbb{E}_S \left[ \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right] - \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \\
\leq \sqrt{\left( 16G^2 n \gamma^2 \mathbb{E}_S \left[ \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right] + 4G^4 n \gamma^4 \right) \log \left( \frac{1}{\zeta} \right)} \\
\leq \frac{1}{2} \mathbb{E}_S \left[ \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right] + \frac{G^2 \gamma^2}{8} + 8G^2 n \gamma^2 \log \left( \frac{1}{\zeta} \right),
\]

where the last inequality holds because \( \sqrt{ab} \leq \frac{a+b}{2} \) for \( a, b > 0 \).

Noting that \( \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \leq M_f L(A_w(S), A_v(S)) \), the inequality above can be written as

\[
\mathbb{E}_S \left[ \mathbb{E}_z \left[ \left( \mathbb{E}_z \left[ \ell(A_w(S), A_v(S); z) \right] \right)^2 \right] \right] - 2M_f L(A_w(S), A_v(S)) \leq \frac{G^2 \gamma^2}{4} + 16G^2 n \gamma^2 \log \left( \frac{1}{\zeta} \right).
\]

(19)
Combining (19) and (18) together, with probability at least $1 - \zeta$, we have

$$L(A_w(S), A_v(S)) - L_S(A_w(S), A_v(S))$$

$$\leq \sqrt{\left(\frac{G^2\gamma^2 + 64G^2n\gamma^2 \log \left(\frac{3}{\zeta}\right)}{2(1-\iota)^2} n \log \left(\frac{3e}{\zeta}\right) + \frac{50\sqrt{2}eG\gamma \log(n) - 3\iota}{1 - \iota} \log \left(\frac{3e}{\zeta}\right) + \frac{12 + 2\iota}{3\iota(1-\iota)} M_L \log \left(\frac{3e}{\zeta}\right)} + \frac{4M_L \log \left(\frac{3e}{\zeta}\right)}{\iota n},$$

where the second inequality holds because $\sqrt{a + b} \leq \sqrt{a} + \sqrt{b}$ for $a, b > 0$ and the last inequality holds because $\sqrt{ab} \leq \frac{1}{2}(a + b)$ for $a, b, \iota > 0$.

By rearranging, we have

$$L(A_w(S), A_v(S)) - \frac{1}{1-\iota} L_S(A_w(S), A_v(S))$$

$$\leq \sqrt{\left(\frac{G^2\gamma^2 + 64G^2n\gamma^2 \log \left(\frac{3}{\zeta}\right)}{2(1-\iota)^2} n \log \left(\frac{3e}{\zeta}\right) + \frac{50\sqrt{2}eG\gamma \log(n) - 3\iota}{1 - \iota} \log \left(\frac{3e}{\zeta}\right) + \frac{12 + 2\iota}{3\iota(1-\iota)} M_L \log \left(\frac{3e}{\zeta}\right)}$$

which ends the proof of part (a).

**Part (b): The Primal generalization error.**

Denoting $v_S^* = \arg \max_{v \in V} L(A_w(S), v)$ and $\bar{v}_S^* = \arg \max_{v \in V} L_S(A_w(S), v)$. We have

$$nR(A_w(S)) - nR_S(A_w(S)) = nL(A_w(S), v_S^*) - nL_S(A_w(S), \bar{v}_S^*)$$

$$= \sum_{i=1}^{n} E_z \left[ \ell \left( A_w(S), v_S^*; z \right) - E_{z_i} \left[ \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z_i \right) \right] \right]$$

$$+ \sum_{i=1}^{n} E_{z_i} \left[ E_z \left[ \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z \right) - \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z_i \right) \right] \right]$$

$$+ \sum_{i=1}^{n} E_{z_i} \left[ \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z_i \right) \right] - \sum_{i=1}^{n} \ell \left( A_w(S), \bar{v}_S^*; z_i \right)$$

Via Lemma III we have

$$\ell \left( A_w(S), v_S^*; z \right) - \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z \right)$$

$$= \ell \left( A_w(S), v_S^*; z \right) - \ell \left( A_w(S^{(i)}), v_S^*; z \right) + \ell \left( A_w(S^{(i)}), v_S^*; z \right) - \ell \left( A_w(S^{(i)}), v_{S^{(i)}}^*; z \right)$$

$$\leq G \left\| A_w(S) - A_w(S^{(i)}) \right\|_2 + G \left\| v_S^* - v_{S^{(i)}}^* \right\|_2$$

$$\leq \left( 1 + \frac{L}{\rho} \right) G \left\| A_w(S) - A_w(S^{(i)}) \right\|_2$$

$$\leq \left( 1 + \frac{L}{\rho} \right) G \gamma.$$
Recalling $p_i(S) = \mathbb{E}_z [\ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z)] - \ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z_i)$, we have

$$
n R(A_w(S)) - n R_S(A_w(S)) \leq \left(1 + \frac{L}{\rho}\right) G n \gamma + \sum_{i=1}^{n} p_i(S) + \sum_{i=1}^{n} \mathbb{E}_z \left[ \ell \left( A_w(S^{(i)}), v^*_{S^{(i)}}; z \right) - \ell \left( A_w(S^{(i)}), v^*_{S^{(i)}}; z_i \right) \right]
$$

$$
= \left(1 + \frac{L}{\rho}\right) G n \gamma + \sum_{i=1}^{n} p_i(S) + \sum_{i=1}^{n} \mathbb{E}_z \left[ \ell \left( A_w(S^{(i)}), v^*_{S^{(i)}}; z \right) - \ell \left( A_w(S^{(i)}), v^*_{S^{(i)}}; z_i \right) \right]
$$

$$
+ \sum_{i=1}^{n} \ell \left( A_w(S), v^*_S; z_i \right) - \sum_{i=1}^{n} \ell \left( A_w(S), v^*_S; z_i \right)
$$

$$
\leq 2 \left(1 + \frac{L}{\rho}\right) G n \gamma + \sum_{i=1}^{n} p_i(S) + \frac{n}{n} \ell \left( A_w(S), v^*_S; z_i \right) - \sum_{i=1}^{n} \ell \left( A_w(S), v^*_S; z_i \right)
$$

$$
\leq 2 \left(1 + \frac{L}{\rho}\right) G n \gamma + \sum_{i=1}^{n} p_i(S),
$$

where the second inequality holds because of Lemma \ref{lemma11} (similar to \ref{lemma21}) and the last inequality holds because $\mathbf{v}_S^* = \arg\max_{\mathbf{v} \in \mathcal{V}} L_S(A_w(S), v)$.

Again, defining $q_i(S) = p_i(S) - \mathbb{E}_{S \setminus \{z_i\}} [p_i(S)]$ and we have $\mathbb{E}_{S \setminus \{z_i\}} [q_i(S)] = 0$ and $\mathbb{E}_{z_i} [q_i(S)] = 0$. Moreover, for any $j = 1, \ldots, n$ (j \neq i) and $z'_j \in \mathcal{Z}$, if we denote $\{z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n\}$ as $S^{(i)}_j$,

$$
q_i(S) - q_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n) = p_i(S) - p_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n)
$$

$$
+ \mathbb{E}_{S \setminus \{z_i\}} [p_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n)] - \mathbb{E}_{S \setminus \{z_i\}} [p_i(S)],
$$

where the first term on the right side

$$
p_i(S) - p_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n) = \mathbb{E}_z \left[ \ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z) - \ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z_i) \right]
$$

$$
\leq \mathbb{E}_z \left[ \ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z) - \ell(A_w(S^{(i)}), v^*_{S^{(i)}}; z_i) \right]
$$

$$
\leq 2 \left(1 + \frac{L}{\rho}\right) G \gamma,
$$

where the inequality holds similar to \ref{lemma21}.

With similar approach, $q_i(S) - q_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, n)$ can be upper bounded by $4 \left(1 + \frac{L}{\rho}\right) G \gamma$, then via Lemma \ref{lemma8} for any $\tau \geq 2$, we have

$$
\left\| \sum_{i=1}^{n} q_i(S) \right\|_\tau \leq 48 \sqrt{2} \left(1 + \frac{L}{\rho}\right) G \tau n \gamma [\log(n)].
$$

(23)

Plugging the result back into \ref{lemma22}, we have

$$
n R(A_w(S)) - n R_S(A_w(S)) - n \mathbb{E}_{S'} [R(A_w(S'))] + n \mathbb{E}_{S'} [R_S(A_w(S'))] \leq \left\| n R(A_w(S)) - n R_S(A_w(S)) - \sum_{i=1}^{n} p_i(S) + \sum_{i=1}^{n} p_i(S) - \sum_{i=1}^{n} \mathbb{E}_{S \setminus \{z_i\}} [p_i(S)] \right\|_\tau
$$

$$
\leq \left\| n R(A_w(S)) - n R_S(A_w(S)) - \sum_{i=1}^{n} p_i(S) \right\|_\tau + \left\| \sum_{i=1}^{n} q_i(S) \right\|_\tau
$$

$$
\leq 50 \sqrt{2} \left(1 + \frac{L}{\rho}\right) G \tau n \gamma [\log(n)],
$$

(24)

where the first equality holds because $n \mathbb{E}_{S'} [R(A_w(S'))] - n \mathbb{E}_{S'} [R_S(A_w(S'))] = \sum_{i=1}^{n} \mathbb{E}_{S \setminus \{z_i\}} [p_i(S)]$, the first inequality holds because of the definition of $q_i(S)$ and the last inequality holds because of \ref{lemma22} and \ref{lemma23}.

Via Lemma \ref{lemma8} for $\zeta \in (0, 1)$, with probability at least $1 - \frac{2}{3}$, we have

$$
R(A_w(S)) - R_S(A_w(S)) \leq \mathbb{E}_{S'} [R(A_w(S'))] - \mathbb{E}_{S'} [R_S(A_w(S'))] + 50 \sqrt{2} \left(1 + \frac{L}{\rho}\right) G \gamma [\log(n)] \log \left(\frac{3e}{\zeta}\right).
$$

(25)
Like discussed before, we have
\[
E_z \left[ \left( E_{S'} \left[ \ell \left( \mathcal{A}_w(S'), \mathbf{v}_{S'}^*; z \right) \right] \right)^2 \right] \leq E_z \left[ E_{S'} \left[ \ell \left( \mathcal{A}_w(S'), \mathbf{v}_{S'}^*; z \right) \right] \right] = E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right].
\]
And as a result, via Lemma 9, with probability at least \(1 - \frac{\zeta}{3}\), we have
\[
\left| E_{S'} \left[ R(\mathcal{A}_w(S')) \right] - E_{S'} \left[ R_S(\mathcal{A}_w(S')) \right] \right| \leq \sqrt{\frac{2n E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 \log \left( \frac{3}{\zeta} \right)}{3n}} + \frac{2M_t \log \left( \frac{4}{\zeta} \right)}{3n}. \tag{26}
\]

Then, we bound \(E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]\).

Defining \(g = g(z_1, \ldots, z_n) = E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2\), and \(g_i = g_i(z_1, \ldots, z_n) = \sup_{z_i \in Z} g(z_1, \ldots, z_n)\), we have
\[
\sum_{i=1}^n (g - g_i)^2 = \sum_{i=1}^n \left( E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 - \sup_{z_i \in Z} E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 \right)^2 \\
\leq \sum_{i=1}^n \left( E_z \left[ \sup_{z_i \in Z} \left( \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right)^2 - \left( \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right)^2 \right) \right)^2 \\
\leq n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 \left( 2E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right] + \left( 1 + \frac{L}{\rho} \right) G^2 \gamma^2 \right)^2 \\
\leq 8n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 g + 2n \left( 1 + \frac{L}{\rho} \right)^4 G^4 \gamma^4,
\]
where the first inequality holds because of Jensen’s inequality, the second inequality holds similar to (21).

Via Definition 7 the inequality above implies that \(g = (a, b)\)-weakly self-bounded where
\[
a = 8n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2, \quad b = 2n \left( 1 + \frac{L}{\rho} \right)^4 G^4 \gamma^4.
\]

As a result, via Lemma 11 with probability at least \(1 - \frac{\zeta}{3}\), we have
\[
E_S \left[ E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 \right] - E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 \\
\leq \left( 16n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 E_S \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right] + 4n \left( 1 + \frac{L}{\rho} \right)^4 G^4 \gamma^4 \right) \log \left( \frac{3}{\zeta} \right) \\
\leq \frac{1}{2} E_S \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 + \frac{1}{8} \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 + 8n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 \log \left( \frac{3}{\zeta} \right).
\]

Noting that \(E_z \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 \leq M_l L \left( \mathcal{A}_w(S), \mathbf{v}_S^* \right) = M_l R \left( \mathcal{A}_w(S) \right)\), we have
\[
E_S \left[ \ell \left( \mathcal{A}_w(S), \mathbf{v}_S^*; z \right) \right]^2 = 2M_l R \left( \mathcal{A}_w(S) \right) \leq \frac{1}{4} \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 + 16n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 \log \left( \frac{3}{\zeta} \right). \tag{27}
\]

Combining (25), (26), and (27) together, then for all \(\epsilon > 0\), with probability at least \(1 - \zeta\), we have
\[
R \left( \mathcal{A}_w(S) \right) - R_S \left( \mathcal{A}_w(S) \right) \\
\leq 50\sqrt{2} \left( 1 + \frac{L}{\rho} \right) G\gamma \left[ \log(n) \right] \log \left( \frac{3\epsilon}{\zeta} \right) + \frac{2M_l \log \left( \frac{4}{\zeta} \right)}{3n} \\
+ \sqrt{\frac{2n}{n} \left( \frac{1}{4} \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 + 16n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 \log \left( \frac{4}{\zeta} \right) + 2M_l R \left( \mathcal{A}_w(S) \right) \right) \log \left( \frac{4}{\zeta} \right)} \\
\leq 50\sqrt{2} \left( 1 + \frac{L}{\rho} \right) G\gamma \left[ \log(n) \right] \log \left( \frac{3\epsilon}{\zeta} \right) + \frac{2M_l \log \left( \frac{4}{\zeta} \right)}{3n} \\
+ \sqrt{\frac{2n}{n} \left( \frac{1}{4} \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 + 32n \left( 1 + \frac{L}{\rho} \right)^2 G^2 \gamma^2 \log \left( \frac{4}{\zeta} \right) \right) \log \left( \frac{4}{\zeta} \right)} + \epsilon R \left( \mathcal{A}_w(S) \right) + \frac{4M_l \log \left( \frac{4}{\zeta} \right)}{n}, \tag{28}
\]

where the last inequality holds because $\sqrt{a + b} \leq \sqrt{a} + \sqrt{b}$ and $\sqrt{ab} \leq \frac{1}{\varepsilon} a + \frac{1}{\varepsilon} b$ for all $a, b, \varepsilon > 0$.

By rearranging, with probability at least $1 - \zeta$, we have

$$R(A_w(S)) - \frac{1}{1 - \varepsilon} R_S(A_w(S)) \leq 50 \sqrt{\frac{(1 + L/\rho)^2 G^2 \gamma^2 (1 + 64n \log(3/\zeta))}{2(1 - \varepsilon)^2 n}} \log \left( \frac{3}{\zeta} \right) + \frac{50 \sqrt{\frac{2 (1 + L/\rho) G \gamma \log(n)}{1 - \varepsilon}} \log \left( \frac{3e}{\zeta} \right) + (12 + 2\varepsilon) M_{\varepsilon}}{3\varepsilon(1 - \varepsilon)n} \log \left( \frac{3}{\zeta} \right),$$

which completes the proof of Part (b).

**Part (c): The primal excess population risk.**

In this section, we denote $w^* = \arg \min_{w \in \mathcal{W}} R(w)$. Then, we have

$$R(A_w(S)) - R(w^*) = \underbrace{R(A_w(S)) - R_S(A_w(S))}_{A} + \underbrace{R_S(A_w(S)) - L_S(w^*, A_w(S))}_{B} + \underbrace{L_S(w^*, A_w(S)) - L(w^*, A_w(S))}_{C} + \underbrace{L(w^*, A_w(S)) - R(w^*)}_{D}.$$

For part $A$, according to (28), with probability at least $1 - \zeta$, we have

$$R(A_w(S)) - R_S(A_w(S)) \leq 50 \sqrt{\frac{(1 + L/\rho)^2 G \gamma \log(n)}{1 - \varepsilon}} \log \left( \frac{3e}{\zeta} \right) + \frac{2M_{\varepsilon} \log \left( \frac{3}{\zeta} \right)}{3n} + \sqrt{\left( \frac{1}{2} (1 + \frac{L}{\rho})^2 G^2 \gamma^2 + 32n (1 + \frac{L}{\rho})^2 G^2 \gamma^2 \log \left( \frac{\delta}{\zeta} \right) + 4M_{\varepsilon} R(A_w(S)) \right) \log \left( \frac{\delta}{\zeta} \right)}.$$

For part $B$, we have

$$R_S(A_w(S)) - L_S(w^*, A_w(S)) \leq R_S(A_w(S)) - L_S(w^*_S, A_w(S)) = \triangle_S^r(A_w(S), A_w(S)), \quad \text{where } w^*_S = \arg \min_{w \in \mathcal{W}} L_S(w, A_w(S)).$$

For part $C$, according to (20), with probability at least $1 - \zeta$, we have

$$L_S(w^*, A_w(S)) - L(w^*, A_w(S)) \leq \frac{2M_{\varepsilon}}{3n} \log \left( \frac{3}{\zeta} \right) + 50 \sqrt{\frac{2eG \gamma \log(n)}{1 - \varepsilon}} \log \left( \frac{3e}{\zeta} \right) + \sqrt{\left( \frac{4M_{\varepsilon} L(w^*, A_w(S)) + G^2 \gamma^2}{2} + 32G^2 n^2 \gamma^2 \log \left( \frac{\delta}{\zeta} \right) \right) \log \left( \frac{\delta}{\zeta} \right)}.$$

For part $D$, it is easy to follow that $L(w^*, A_w(S)) - R(w^*) \leq 0$.

Combining parts $A, B, C, D$ together, with probability at least $1 - \zeta$, we have

$$R(A_w(S)) - R(w^*) \leq 50 \sqrt{\frac{(1 + L/\rho)^2 G \gamma \log(n)}{1 - \varepsilon}} \log \left( \frac{6e}{\zeta} \right) + \frac{4M_{\varepsilon}}{3n} \log \left( \frac{6}{\zeta} \right) + \triangle_S^r(A_w(S), A_w(S)) + \sqrt{\left( \frac{1}{2} (1 + \frac{L}{\rho})^2 G^2 \gamma^2 + 32n (1 + \frac{L}{\rho})^2 G^2 \gamma^2 \log \left( \frac{6}{\zeta} \right) + 4M_{\varepsilon} R(A_w(S)) \right) \log \left( \frac{6}{\zeta} \right)} + \frac{4M_{\varepsilon} R(w^*) + G^2 \gamma^2}{2} + 32G^2 n^2 \gamma^2 \log \left( \frac{6}{\zeta} \right) \log \left( \frac{6}{\zeta} \right) + \sqrt{\left( \frac{G^2 \gamma^2}{2} + 32G^2 n^2 \gamma^2 \log \left( \frac{6}{\zeta} \right) \right) \log \left( \frac{6}{\zeta} \right)} + \frac{8M_{\varepsilon}}{n \eta \log \left( \frac{6}{\zeta} \right)} + \frac{8M_{\varepsilon}}{n \eta \log \left( \frac{6}{\zeta} \right)},$$
where the first inequality holds because \( L(w^*, A_\nu(S)) \leq R(w^*) \) and the last inequality holds because \( \sqrt{a + b} \leq \sqrt{a} + \sqrt{b} \) and \( \sqrt{ab} \leq \frac{a + b}{2} \) for all \( a, b, t > 0 \).

By rearranging, for all \( \ell > 0 \), with probability at least \( 1 - \zeta \), we have

\[
R(A_w(S)) - \frac{1 + \ell}{1 - \ell} \inf_{w \in W} R(w) \leq \sqrt{\frac{(1 + L/\rho)^2 G^2 \gamma^2 (1 + 64n \log(6/\zeta))}{2(1 - \ell)^2 n}} \log \left( \frac{6}{\ell} \right) + \sqrt{\frac{(G^2 \gamma^2 + 64G^2 \gamma^2 \log(6/\zeta))}{2(1 - \ell)^2 n}} \log \left( \frac{6}{\ell} \right) + \frac{1}{1 - \ell} \Delta^*(A_w(S), A_\nu(S)).
\]

The proof of part (c) completes.

**Part (d): The strong PD population risk.**

Denoting \( w^*_S = \arg \min_{w \in W} L(w, A_\nu(S)) \), \( \bar{w}^*_S = \arg \min_{w \in W} L_S(w, A_\nu(S)) \), \( v^*_S = \arg \max_{v \in V} L(A_w(S), v) \), and \( \bar{v}^*_S = \arg \max_{v \in V} L_S(A_w(S), v) \). We have

\[
\Delta^*(A_w(S), A_\nu(S)) = \sup_{v \in V} L(A_w(S), v) - \inf_{w \in W} L(w, A_\nu(S))
= L(A_w(S), v^*_S) - L_S(A_w(S), \bar{v}^*_S) + E_S [L_S(A_w(S'), v^*_S)] - E_S [L(A_w(S), v^*_S)]
+ E_S [L(w^*_S, A_\nu(S))] - E_S [L_S(w^*_S, A_\nu(S'))] + L_S(\bar{w}^*_S, A_\nu(S)) - L(\bar{w}^*_S, A_\nu(S))
- E_S [L(A_w(S'), v^*_S)] - E_S [L(w^*_S, A_\nu(S))] + E_S [L(w^*_S, A_\nu(S'))]
+ L_S(\bar{w}^*_S, A_\nu(S)) - L_S(\bar{w}^*_S, A_\nu(S))
\]

For part A, via inequality (24), for \( \tau \geq 2 \), we have

\[
\| R(A_w(S)) - R_S(A_w(S)) - E_S'[R(A_w(S'))] + E_S'[R(S_A(S'))] \|_{\tau} = \| L(A_w(S), v^*_S) - L_S(A_w(S), \bar{v}^*_S) + E_S[L_S(A_w(S'), v^*_S)] - E_S[L(A_w(S), v^*_S)] + E_S[L(w^*_S, A_\nu(S))] - E_S[L_S(w^*_S, A_\nu(S'))] + L_S(\bar{w}^*_S, A_\nu(S)) - L(\bar{w}^*_S, A_\nu(S)) - E_S[L(A_w(S'), v^*_S)] - E_S[L(w^*_S, A_\nu(S))] + E_S[L(w^*_S, A_\nu(S'))] + L_S(\bar{w}^*_S, A_\nu(S)) - L_S(\bar{w}^*_S, A_\nu(S)) \|_{\tau} \leq 50\sqrt{2} \left( 1 + \frac{L}{\rho} \right) G\tau \gamma [\log(n)].
\]

For part B, we first analyze

\[
n L_S(\bar{w}^*_S, A_\nu(S)) - n L(w^*_S, A_\nu(S)) = n L_S(\bar{w}^*_S, A_\nu(S)) - \sum_{i=1}^n \mathbb{E}_z \left( \ell(\bar{w}^*_S, A_\nu(S); z) - \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) \right)
+ \sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \mathbb{E}_z \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right),
\]

in which

\[
\sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) = \sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \ell(w^*_S, A_\nu(S); z) + \ell(w^*_S, A_\nu(S); z) \geq n L_S(\bar{w}^*_S; A_\nu(S)) + \sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \ell(w^*_S, A_\nu(S); z),
\]

where the last inequality holds because \( w^*_S = \arg \min_{w \in W} L_S(w, A_\nu(S)) \).

Defining \( p_i(S) = \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \mathbb{E}_z \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) \) and plugging (31) back into (30), we have

\[
n L_S(\bar{w}^*_S, A_\nu(S)) - n L(w^*_S, A_\nu(S)) \leq - \sum_{i=1}^n \mathbb{E}_z \left( \ell(w^*_S, A_\nu(S); z) - \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) \right) + \sum_{i=1}^n p_i(S)
- \sum_{i=1}^n \mathbb{E}_z' \left( \ell(w^*_S(i), A_\nu(S^i)); z \right) - \ell(w^*_S, A_\nu(S); z) \right).
Similar to (21), via Lemma [11] we have
\[ nL_S(\bar{w}_S, A_\nu(S)) - nL(w^*_S, A_\nu(S)) \leq \sum_{i=1}^{n} p_i(S) + \frac{2}{n} L \left( 1 + \frac{L}{\rho} \right) G \gamma. \]

Again, we define \( q_i(S) = p_i(S) - \mathbb{E}_{S \setminus \{z_i\}}[p_i(S)] \) and have \( \mathbb{E}_{S \setminus \{z_i\}}[q_i(S)] = \mathbb{E}_{z_i}[q_i(S)] = 0 \). Similarly, for \( j = 1, \ldots, n \) \((j \neq i)\) and \( z'_j \in Z \), we have
\[ q_i(S) - q_i(z_1, \ldots, z_{j-1}, z'_j, z_{j+1}, \ldots, z_n) \leq 4 \left( 1 + \frac{L}{\rho} \right) G \gamma, \]
which implies
\[ \left\| \sum_{i=1}^{n} q_i(S) \right\|_{\tau} \leq 48\sqrt{2} \left( 1 + \frac{L}{\rho} \right) G \gamma [\log(n)], \]
for \( \tau \geq 2 \), via Lemma [6].

Then for part \( B \), like in (24), for \( \tau \geq 2 \), we have
\[ \|E_S[L(A_w(S'), v'_{S'})] - E_{S'}[L_S(\bar{w}_{S'}^*, A_\nu(S'))] + L_S(\bar{w}_{S'}^*, A_\nu(S)) - L(\bar{w}_{S'}^*, A_\nu(S))\|_{\tau} \]
\[ \leq \left\| L_S(\bar{w}_{S'}^*, A_\nu(S)) - L(\bar{w}_{S'}^*, A_\nu(S)) \right\|_{\tau} + \left\| \frac{1}{n} \sum_{i=1}^{n} p_i(S) \right\|_{\tau} + \left\| \frac{1}{n} \sum_{i=1}^{n} q_i(S) \right\|_{\tau} \]
\[ \leq 50\sqrt{2} \left( 1 + \frac{L}{\rho} \right) G \gamma [\log(n)]. \] (32)

For part \( C \), we have
\[ - E_{S'}[L_S(A_w(S'), v'_{S'})] + E_S[L(A_w(S), v'_{S'})] - E_S[L(\bar{w}_S^*, A_\nu(S))] + E_{S'}[L_S(\bar{w}_{S'}^*, A_\nu(S'))] \]
\[ = \frac{1}{n} \sum_{i=1}^{n} (-E_{S'}[\ell(A_w(S'), v'_{S'}; z_i)] + E_S[\ell(\bar{w}_S^*, A_\nu(S'); z_i)]) + E_S[L(A_w(S), v'_{S'})] - E_S[L(\bar{w}_S^*, A_\nu(S))]. \] (33)

Defining \( g_i = u + v_i \), where \( u = E_S[\ell(A_w(S), v'_{S'})] - E_S[L(\bar{w}_S^*, A_\nu(S))] \), and \( v_i = E_{S'}[\ell(\bar{w}_{S'}^*, A_\nu(S'); z_i)] - E_{S'}[\ell(A_w(S'), v'_{S'}; z_i)] \). Then \( g_i \) is the element in (33).

Besides, we have \( E[g_i^2] \leq E[(g_i - E[g_i])^2] \). Noting that \( E_S[E_{S'}[L_S(\bar{w}_{S'}^*, A_\nu(S'))] - E_{S'}[L_S(A_w(S'), v'_{S'})]] = E_S[L(\bar{w}_S^*, A_\nu(S))] - E_S[L(A_w(S), v'_{S'})] = -u \), so \( E[g_i^2] \leq E[(g_i - E[g_i])^2] = E[v_i^2] \), i.e., \( E[g_i^2] \) can be bounded by \( E[v_i^2] \).

For \( E[v_i^2] \), we have
\[ E[v_i^2] = E\left[\left(E_{S'}[\ell(\bar{w}_S^*, A_\nu(S'); z_i)] - E_{S'}[\ell(A_w(S'), v'_{S'}; z_i)]\right)^2\right] \]
\[ \leq E\left[\left(E_{S'}[\ell(\bar{w}_S^*, A_\nu(S')); z_i)] - E_{S'}[\ell(A_w(S'), v'_{S'}; z_i)]\right)^2\right] \]
\[ \leq 2G^2E\left[\left(E_{S'}[\ell(\bar{w}_S^*, A_\nu(S')); z_i)] - E_{S'}[\ell(A_w(S'), v'_{S'}; z_i)]\right)^2\right], \] (34)

where the first inequality holds because of Jensen’s inequality and the \( G \)-Lipschitz property of \( \ell(\cdot, \cdot, \cdot) \), and the second inequality holds because \((a + b)^2 \leq 2(a^2 + b^2)\).

Noting that \( L(\cdot, \cdot) \) is \( \rho \)-strongly-convex-strongly-concave, we have
\[ \frac{\rho}{2} \|A_\nu(S') - v_{S'}^*\|_2^2 \leq L(\bar{w}_S^*, v_{S'}^*) - L(\bar{w}_{S'}^*, A_\nu(S')), \]
\[ \frac{\rho}{2} \|A_\nu(S') - v_{S'}^*\|_2^2 \leq L(A_w(S'), v_{S'}^*) - L(\bar{w}_{S'}^*, v_{S'}^*). \]

As a result
\[ \|A_\nu(S') - v_{S'}^*\|_2^2 + \|A_\nu(S') - v_{S'}^*\|_2^2 \leq \frac{2}{\rho} (L(A_w(S'), v_{S'}^*) - L(\bar{w}_{S'}^*, A_\nu(S'))). \]

Plugging this result back into (34), we have
\[ E\left[\left(E_{S'}[\ell(\bar{w}_{S'}^*, A_\nu(S')); z_i)] - E_{S'}[\ell(A_w(S'), v_{S'}^*; z_i)]\right)^2\right] \leq \frac{4G^2}{\rho} E_{S'}[L(\bar{w}_{S'}^*, A_\nu(S')) - L(\bar{w}_{S'}^*, A_\nu(S'))] \]
\[ = \frac{4G^2}{\rho} E_S[L(A_w(S), v_{S}^*) - L(\bar{w}_{S}^*, A_\nu(S))]. \]
Then, via Lemma 12 for part C, for \( \tau \geq 2 \), we have

\[
\left\| \frac{1}{n} \sum_{i=1}^{n} \left( -E_{S'} [\ell (A_{W}(S'), \nu_{S'}; z_i)] + E_{S'} [\ell (w_{S'}, A_{V}(S'); z_i)] + E_S [L (A_{W}(S), \nu_{S'})] - E_S [L (w_{S'}, A_{V}(S))] \right) \right\|_{r} \leq 6 \sqrt{\frac{AG^2 \tau}{\rho n}} E_S [L (A_{W}(S), \nu_{S'}) - L (w_{S'}, A_{V}(S))] + \frac{8M_{\tau}}{n}. \tag{35}
\]

For part D, \( L_S (A_{W}(S), \nu_{S'}) - L_S (w_{S'}, A_{V}(S)) \) is exactly the strong PD empirical risk \( \Delta_S^\tau (A_{W}(S), A_{V}(S)) \). Plugging (29), (32), and (35) back into \( \Delta^\tau (A_{W}(S), A_{V}(S)) \), then for all \( \tau \geq 2 \), we have

\[
\left\| \Delta^\tau (A_{W}(S), A_{V}(S)) - \Delta_S^\tau (A_{W}(S), A_{V}(S)) \right\|_{r} \leq 100 \sqrt{2} \left( 1 + \frac{L}{\rho} \right) G_{\gamma} [\log(n)] + 12 \sqrt{\frac{G^2 \tau}{\rho n}} E_S [L (A_{W}(S), \nu_{S'}) - L (w_{S'}, A_{V}(S))] + \frac{8M_{\tau}}{n} \leq 100 \sqrt{2} \left( 1 + \frac{L}{\rho} \right) G_{\gamma} [\log(n)] + 288 \frac{G^2}{\rho n} + \frac{16M_{\tau}}{n} + \frac{144G^2 \tau}{\rho n} + \frac{8M_{\tau}}{n}, \tag{36}
\]

where the last inequality holds because \( \sqrt{ab} \leq \frac{1}{\tau} a + \frac{1}{\tau} b \) for \( a, b, \tau > 0 \).

Noting that

\[
E_S [\Delta^\tau (A_{W}(S), A_{V}(S)) - \Delta_S^\tau (A_{W}(S), A_{V}(S))] \leq \left\| \Delta^\tau (A_{W}(S), A_{V}(S)) - \Delta_S^\tau (A_{W}(S), A_{V}(S)) \right\|_{2} \leq 200 \sqrt{2} \left( 1 + \frac{L}{\rho} \right) G_{\gamma} [\log(n)] + \frac{288G^2}{\rho n} + \frac{16M_{\tau}}{n} + \frac{144G^2 \tau}{\rho n} + \frac{8M_{\tau}}{n},
\]

where the last inequality holds because of the Cauchy-Schwartz inequality, which implies

\[
E_S [\Delta^\tau (A_{W}(S), A_{V}(S))] = \frac{1}{1 - \ell} E_{S} [\Delta_S^\tau (A_{W}(S), A_{V}(S))] \leq \frac{1}{1 - \ell} \left( 200 \sqrt{2} \left( 1 + \frac{L}{\rho} \right) G_{\gamma} [\log(n)] + \frac{288G^2}{\rho n} + \frac{16M_{\tau}}{n} \right).
\]

Plugging the result back into (36), then for \( \tau \geq 2 \), we have

\[
\left\| \Delta^\tau (A_{W}(S), A_{V}(S)) - \Delta_S^\tau (A_{W}(S), A_{V}(S)) \right\|_{r} \leq \frac{\ell \tau}{1 - \ell} \left( E_S [\Delta_S^\tau (A_{W}(S), A_{V}(S))] + 200 \sqrt{2} \left( 1 + \frac{L}{\rho} \right) G_{\gamma} [\log(n)] + \frac{288G^2}{\rho n} + \frac{16M_{\tau}}{n} \right) + \frac{144G^2 \tau}{\rho n} + \frac{8M_{\tau}}{n}.
\]

Via Lemma 3 with probability at least \( 1 - \zeta \), we have

\[
\Delta^\tau (A_{W}(S), A_{V}(S)) \leq \frac{100 \sqrt{2} e(1 + \ell)(1 + L/\rho)G_{\gamma} [\log(n)]}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + \frac{144e(1 + \ell)G^2}{(1 - \ell)n} \log \left( \frac{e}{\zeta} \right) + \frac{8e(1 + \ell)M_{\tau}}{n(1 - \ell)} \log \left( \frac{e}{\zeta} \right) + \frac{144G^2 \tau}{\rho n} + \frac{8M_{\tau}}{n}, \tag{37}
\]

which completes the proof of part (d) and Theorem 3.

\[ \square \]

**Proof of Lemma 2**

Lemma 13. If Assumptions 7 and 8 hold. Taking \( \sigma \) given in Theorem 1 and \( \eta = \frac{1}{\rho \tau} \), then with probability at least \( 1 - \zeta \) for \( \zeta \in (\exp(-\frac{L}{\rho}), 1) \), the strong primal dual empirical risk of the output of DP-GDA: \( \hat{A}(S) = (\hat{w}_T, \hat{v}_T) \) satisfies

\[
\Delta_S^\tau (\hat{w}_T, \hat{v}_T) \leq \frac{G^2 \log(eT)}{\rho T} + \frac{cG(g_w + g_v)\sqrt{T p \log(1/\delta)}}{n \epsilon} p_c + cG^2 \log(eT) \left( \frac{p \log(1/\delta)}{\rho n^2 \epsilon^2} p_c^2 + \frac{2 \sqrt{p \log(1/\delta)}}{\rho \sqrt{T n \epsilon}} p_c \right),
\]

for some constant \( c \), where \( p_c, g_w, g_v \) are defined as in Theorem 2.
Proof. In Appendix A.2, we have analyzed the strong PD empirical risk in (8). So, via the connection between the argument stability and the strong PD empirical risk (see (9), along with plugging the random noise \( \mathbf{w} \) and \( \mathbf{v} \) into it (see (11)), we have

\[
\Delta_S^* (\bar{w}_T, \bar{v}_T) \leq \frac{G^2 \log(eT)}{\rho T} + \frac{\sigma^2 p \log(eT) p_\zeta^2}{\rho T} + \frac{2G\sigma \sqrt{p} \log(eT)}{\rho T} p_\zeta + (g_w + g_v) \sigma \sqrt{pp_\zeta},
\]

where \( p_\zeta = 1 + \left( \frac{8 \log(2T/\zeta)}{p} \right)^{1/4} \). \( g_w = \| \bar{w}_* - \bar{w}_T \|_2 \), and \( g_v = \| \bar{v}_* - \bar{v}_T \|_2 \) for \( \bar{w}_* = \arg \max_{\mathbf{w} \in \mathcal{W}} L_S(\mathbf{w}, \bar{v}_T) \), and \( \bar{v}_* = \arg \max_{\mathbf{v} \in \mathcal{V}} L_S(\bar{w}_T, \mathbf{v}) \).

Taking \( \sigma \) given in Theorem 11 then the proof completes. \( \square \)

Proof of Corollary 1

Corollary 2. With argument stability parameter \( \gamma \),

(a) Under the condition given in Theorem 3 part (d), the strong PD generalization error satisfies

\[
\Delta^* (A_w(S), A_v(S)) - \Delta^*_S (A_w(S), A_v(S)) \leq \frac{100\sqrt{2e(1 + \ell)(1 + L/p)G\gamma \log(n)}}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + \frac{144e(1 + \ell)G^2}{\rho(1 - \ell)n} \log \left( \frac{e}{\zeta} \right) + \frac{8e(1 + \ell)M_f}{n(1 - \ell)} \log \left( \frac{e}{\zeta} \right) + \left( \frac{e\ell}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + 1 \right) \Delta^*_S (A_w(S), A_v(S)).
\]

(b) Under the condition given in Theorem 3 part (d), the weak primal dual population risk satisfies

\[
\Delta^w (A_w(S), A_v(S)) \leq \frac{100\sqrt{2e(1 + \ell)(1 + L/p)G\gamma \log(n)}}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + \frac{144e(1 + \ell)G^2}{\rho(1 - \ell)n} \log \left( \frac{e}{\zeta} \right) + \frac{8e(1 + \ell)M_f}{n(1 - \ell)} \log \left( \frac{e}{\zeta} \right) + \left( \frac{e\ell}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + 2 \right) \Delta^*_S (A_w(S), A_v(S)).
\]

(c) Under the condition given in Theorem 3 part (d), the weak PD generalization error satisfies

\[
\Delta^w (A_w(S), A_v(S)) - \Delta^*_S (A_w(S), A_v(S)) \leq \frac{100\sqrt{2e(1 + \ell)(1 + L/p)G\gamma \log(n)}}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + \frac{144e(1 + \ell)G^2}{\rho(1 - \ell)n} \log \left( \frac{e}{\zeta} \right) + \frac{8e(1 + \ell)M_f}{n(1 - \ell)} \log \left( \frac{e}{\zeta} \right) + \left( \frac{e\ell}{1 - \ell} \log \left( \frac{e}{\zeta} \right) + 2 \right) \Delta^*_S (A_w(S), A_v(S)).
\]

\( \Delta_S^* (A_w(S), A_v(S)) \) together with its expectation and omit the absolute value of \( \mathbb{E} [\Delta^*_S (A_w(S), A_v(S))] \) because it is the upper bound of \( \Delta^*_S (A_w(S), A_v(S)) \) who matters.

The proof completes. \( \square \)
