Abstract

Convolutional neural network (CNN) has achieved impressive success in computer vision during the past few decades. The image convolution operation helps CNNs to get good performance on image-related tasks. However, the image convolution has high computation complexity and hard to be implemented. This paper proposes the CEMNet, which can be trained in the frequency domain. The most important motivation of this research is that we can use the straightforward element-wise multiplication operation to replace the image convolution in the frequency domain based on the Cross-Correlation Theorem, which obviously reduces the computation complexity. We further introduce a Weight Fixation mechanism to alleviate the problem of over-fitting, and analyze the working behavior of Batch Normalization, Leaky ReLU, and Dropout in the frequency domain to design their counterparts for CEMNet. Also, to deal with complex inputs brought by Discrete Fourier Transform, we design a two-branches network structure for CEMNet. Experimental results imply that CEMNet achieves good performance on MNIST and CIFAR-10 databases.

1 Introduction

In the past few decades, CNN [LeCun and Bengio, 1995] has played an essential role in the field of computer vision. Even though ViT [Dosovitskiy et al., 2021] shows excellent performance on vision tasks, CNN is still an irreplaceable tool for researchers and real-world users. The core of CNN is the image convolution operation, which is very complicated and hard to be implemented and parallelized. Based on theorems of signal processing, image convolution can be replaced by the straightforward element-wise multiplication via converting input data into the frequency domain using Discrete Fourier Transform (DFT) (see Section 2 for more details). In this way, we may
simplify the forward and backward calculations of convolution layers and make them easier to be parallelized. Moreover, Xu et al. [2019] implies that CNNs may firstly capture low-frequency components of features, then high-frequency components. In Wang et al. [2020], authors emphasized that high-frequency components play important roles in the generalization of CNNs, even though they are almost imperceptible to human beings. Those researches imply that directly learning CNNs in the frequency domain may allow us to learn features of low-frequency and high-frequency components explicitly, then help us find more information to explain how CNNs work.

There are many efforts to implement CNNs in the frequency domain. Mathieu et al. [2014] is an early research that considered to do convolution operation in the frequency domain. During the forward pass, the algorithm firstly transfers input feature maps and convolution filters into the Fourier domain, then applies the element-wise multiplication between them instead of the image convolution. After that, the result feature maps should be moved back to the time domain. The method achieved good efficiency but it could not learn convolution filters directly in the frequency domain. Vasilache et al. [2015], Lavin and Gray [2016], and Li et al. [2020] mainly focused on the inference stage. Those researches implied that transferring well-trained CNNs into the frequency domain may obviously speed-up during the inference stage.

In Rippel et al. [2015] and Ryu et al. [2018], DFT was applied on pooling layers of CNNs and result in good image classification performances. Watanabe and Wolf [2021] analyzed working behaviors of convolution layers, Batch Normalization, and ReLU in the frequency domain, and proposed a novel ReLU layer called 2SReLU that can work in the frequency domain. A convolution-free neural network with 2SReLU layers was trained in the frequency domain using MNIST and AT&T databases. Pratt et al. [2017] proposed a Fourier Convolution Neural Network (FCNN), which includes Fourier Convolution Layers and Fourier Pooling Layers. FCNN can be trained entirely in the frequency domain using MNIST and CIFAR-10 databases. Different from the works above, Goldberg et al. [2020] used Discrete Cosine Transform (DCT) to covert features to the frequency domain and result in a model family with good performance.

In this paper, we propose a novel computation model, namely CEMNet (Complex Element-wise Multiplication Network). CEMNet can be viewed as a counterpart of CNNs, which mainly works in the frequency domain. We provide theoretical analyses of convolution layers, Batch Normalization, Leaky ReLU and Dropout in the frequency domain, and propose corresponding layers to construct the CEMNet. Moreover, we design a two-branches structure to implement the CEMNet for complex inputs derived by DFT. The experimental results on MNIST and CIFAR-10 databases show that the proposed CEMNet has good performances on image classification tasks and less number of operations. The main contributions of this paper include:

(1) We propose the CEMNet that can be trained directly in the frequency domain, and using an element-wise multiplication to replace the image convolution operation of CNNs to reduce the computation complexity. Moreover, we introduce a Weight Fixation mechanism to deal with the over-fitting problem.

(2) We implement Batch Normalization, Leaky ReLU, and Dropout in the frequency domain to improve the performance of CEMNet, and design a two-branches structure for CEMNet to make it work with complex inputs.

(3) To the best of our knowledge, CEMNet is the first model trained in the frequency domain that can achieve more than 70% validation accuracy on CIFAR-10 database.

2 Mathematical Basis

In the field of signal processing, Convolution Theorem is one of the basic calculation rule. Assuming that $x$ and $y$ are two casual signals in time domain, $*$ the convolution operation, and $F(\cdot)$ the Discrete Fourier transform (DFT), then we have:

$$F(x \ast y) = F(x) \cdot F(y)$$

where $\cdot$ is the element-wise multiplication.

Several previous studies consider to apply the Convolution Theorem on CNNs to transfer the complicated image convolution operation to the simple element-wise multiplication. However, the so-called
image convolution in CNNs is in fact the cross-correlation operation in signal processing. Thus we need to consider the **Cross-Correlation Theorem**:

\[
F(R(x, y)) = F^*(x) \cdot F(y)
\]  

(2)

where \( R(x, y) \) is the cross-correlation between \( x \) and \( y \), and \( F^*(x) \) is the conjugate complex number of \( F(x) \).

Eq. (2) serves as an important basis of our research since it builds a relationship between the time domain and frequency domain for convolution layers in CNNs.

3 Method

In this section, we firstly introduce necessary network layers in the frequency domain, then propose the implementation method of CEMNet.

3.1 Important Layers

3.1.1 Element-wise Multiplication Layer

Based on Section 2, the image convolution operation in the time domain can be replaced by using element-wise multiplication in the frequency domain. Therefore, we design the element-wise multiplication layer as the most important part of CEMNet.

Assuming that we have a convolution layer \( L \), which has \( H_1 \times H_2 \times C_{in} \) sized input feature map \( I_L \) and \( H_1 \times H_2 \times C_{out} \) sized output feature map \( O_L \). Notice that here we only consider the situation that \( I_L \) and \( O_L \) have the same \( H_1 \) and \( H_2 \). The convolution filter \( W \) of \( L \) has the size of \( K \times K \times C_{in} \times C_{out} \), where \( K \leq H_1 \) and \( K \leq H_2 \). Thus the forward process of \( L \) is:

\[
O_L = I_L \ast W
\]  

(3)

where \( \ast \) is the image convolution operation (which is in fact the cross-correlation in signal processing). It is easy to know that the computation complexity of one convolution layer is \( O(K^2 \times H_1 \times H_2 \times C_{in} \times C_{out}) \). According to Eq. (2) the corresponding operation of Eq. (4) in the frequency domain is:

\[
F(O_L) = F^*(I_L) \cdot F(W_p)
\]  

(4)

Notice that we should firstly do zero-padding on \( W \) to generate the padded filter \( W_p \) to guarantee that it has the same height and width as \( I_L \). In our research, we simply put \( W \) at the upper-left corner of \( W_p \) and set the rest elements of \( W_p \) to 0. We can easily find that the computation complexity of one Element-wise Multiplication Layer is reduced to \( O(H_1 \times H_2 \times C_{in} \times C_{out}) \).

Eq. (4) is the forward calculation of the proposed element-wise multiplication layer, and it is very easy to derive the backward calculation:

\[
\frac{\partial F(O_L)}{\partial F(W_p)} = F^*(I_L)
\]  

(5)

Eq. (5) implies that the gradient calculation of element-wise multiplication layers is much easier than regular convolution layers.

Unfortunately, if we use the above-mentioned equations directly to implement an element-wise multiplication layer, it may not result in a good performance. The main reason for this fact can be attributed to the over-fitting problem. CNNs use local receptive fields to reduce the number of free parameters, thus in most cases, convolution filters tend to be much smaller than input features. For instance, a convolution layer with \( 32 \times 32 \times 3 \) sized \( I_L \) may only need to use a \( 3 \times 3 \times 3 \times 64 \) sized \( W \) to output \( 32 \times 32 \times 64 \) sized \( O_L \), and in this case the number of free parameters is only 1728. However, if we transfer this convolution layer into the frequency domain, the scale of \( F(W_p) \)
becomes \(32 \times 32 \times 3 \times 64\), which corresponds to 196,608 free parameters. The sharply increased free parameters mean that the over-fitting may happen much easier on CEMNets. To fix this problem, we introduce a **Weight Fixation** mechanism during the training process. Specifically, \(F(W_p)\) should be transferred back to the time domain (still denoted by \(W_p\)) after each weight update. After that, we perform an element-wise multiplication among \(W_p\) and a Weight Fixation matrix \(V\), where \(V\) is a \(0-1\) matrix and only upper-left \(K \times K\) elements are set to 1. Thus Eq. 4 becomes:

\[
F(O_L) = F^*(I_L) \cdot F(W_p \cdot V)
\]

Even though the proposed Weight Fixation mechanism slows down the training process, it can obviously improve network performance.

### 3.1.2 Batch Normalization

Batch Normalization [Ioffe and Szegedy 2015] is a widely-used regularization method in deep learning. By normalizing each training mini-batch, Batch Normalization, to a large extent, solves the problem of internal covariance shift, and improves the stability of the training process. Assuming that \(B = x_1, x_2, ..., x_S\) is a training mini-batch with batch size \(S\), the basic procedure of Batch Normalization can be divided into two steps:

1. Normalization: we should firstly calculate the mean \(\mu_B\) and variance \(\sigma_B\) over the mini-batch \(B\), then normalize training samples in \(B\):

   \[
   \hat{x}_i = \frac{x_i - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}}, \quad i = 1, \ldots, S
   \]

   where \(\epsilon\) is a small enough constant to prevent zero-denominator.

2. Scale and shift: in this step two learnable parameters \(\gamma\) and \(\beta\) are introduced to perform the Batch Normalization Transform on \(\hat{x}_i\):

   \[
   BNT_{\gamma,\beta}(x_i) = \gamma \hat{x}_i + \beta, \quad i = 1, \ldots, S
   \]

Based on the definition of Discrete Fourier Transform, we transfer time domain features to the frequency domain follow the Eq. 9:

\[
\begin{align*}
F_{\text{real}}(x, y) &= \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \\
F_{\text{imag}}(x, y) &= -\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x, y) \sin(2\pi \frac{ux}{M} + \frac{vy}{N})
\end{align*}
\]

where \(F_{\text{real}}(x, y)\) and \(F_{\text{imag}}(x, y)\) are the real part and imaginary part of the features in the frequency domain respectively. If we perform Batch Normalization on the time domain, then \(F_{\text{real}}(x, y)\) becomes:

\[
\begin{align*}
F_{i,\text{real}}(x, y) &= \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left( \gamma \frac{f_i(x, y) - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}} + \beta \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \right) \\
&= \frac{\gamma}{\sqrt{\sigma_B^2 + \epsilon}} \left( \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} (f_i(x, y) - \mu_B) \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \right) + \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \beta \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \\
&= \frac{\gamma}{\sqrt{\sigma_B^2 + \epsilon}} F_{i,\text{real}}(x, y) - \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \mu_B \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) + \beta_{\text{real}}, \quad i = 1, \ldots, S
\end{align*}
\]
where $\gamma$ and $\beta_{\text{real}}$ can be viewed as a learnable parameter. Moreover, we have:

$$F_{\text{real}}(\mu_B) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left( \frac{1}{K} \sum_{i=1}^{k} f_i(x, y) \right) \cos \left( 2\pi \left( \frac{ux}{M} + \frac{vy}{N} \right) \right)$$

$$= \frac{1}{K} \sum_{i=1}^{k} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f_i(x, y) \cos \left( 2\pi \left( \frac{ux}{M} + \frac{vy}{N} \right) \right)$$

(11)

therefore, Eq. (10) becomes:

$$F^{BNT}_{i,\text{real}}(x, y) = \gamma F_{i,\text{real}}(x, y) - \mu_{F,\text{real}} \sqrt{\sigma^2_{B,\text{real}}} + \beta_{\text{real}}, i = 1, ..., S$$

(12)

Similarly, we can get the corresponding $F^{BNT}_{i,\text{imag}}(x, y)$ as below:

$$F^{BNT}_{i,\text{imag}}(x, y) = \gamma F_{i,\text{imag}}(x, y) - \mu_{F,\text{imag}} \sqrt{\sigma^2_{B,\text{imag}}} + \beta_{\text{imag}}, i = 1, ..., S$$

(13)

It is easy to find that Eq. (12) and Eq. (13) have similar form as the function of Batch Normalization in Eq. (8). The main difference is that $F^{BNT}_{i,\text{real}}(x, y)$ and $F^{BNT}_{i,\text{imag}}(x, y)$ share the variance of the time domain $\sigma^2_B$ as the denominator. Considering the variance of real part and imaginary part over each training mini-batch in the frequency domain, which can be denoted as $\sigma^2_{F,\text{real}}$ and $\sigma^2_{F,\text{imag}}$. Since $\sigma^2_B, \sigma^2_{F,\text{real}}$, and $\sigma^2_{F,\text{imag}}$ are constant for each mini-batch, we can assume that $\frac{\sigma^2_B}{\sigma^2_{F,\text{real}}} = C_{\text{real}}$ and $\frac{\sigma^2_B}{\sigma^2_{F,\text{imag}}} = C_{\text{imag}}$, where $C_{\text{real}}$ and $C_{\text{imag}}$ are constants. Because $\epsilon$ is a negligible constant, Eq. (12) and Eq. (13) can be re-written as:

$$F^{BNT}_{i,\text{real}}(x, y) = \frac{\gamma}{\sqrt{C_{\text{real}}}} F_{i,\text{real}}(x, y) - \frac{\mu_{F,\text{real}}}{\sqrt{\sigma^2_{F,\text{real}}} + \epsilon} + \beta_{\text{real}}, i = 1, ..., S$$

(14)

and

$$F^{BNT}_{i,\text{imag}}(x, y) = \frac{\gamma}{\sqrt{C_{\text{imag}}}} F_{i,\text{imag}}(x, y) - \frac{\mu_{F,\text{imag}}}{\sqrt{\sigma^2_{F,\text{imag}}} + \epsilon} + \beta_{\text{imag}}, i = 1, ..., S$$

(15)

where $\frac{\gamma}{\sqrt{C_{\text{real}}}}$ and $\frac{\gamma}{\sqrt{C_{\text{imag}}}}$ can be viewed as learnable parameters.

Based on the analyses above, we can learn that the implementation of Batch Normalization in the frequency domain has exactly the same form as the time domain. Thus in practice, we can directly do Batch Normalization on the real part and imaginary part of complex features in each mini-batch respectively.

### 3.1.3 Dropout

Dropout [Srivastava et al. 2014] is another widely-used regularization method for deep neural networks. By randomly dropping part of neurons during the training process, Dropout obviously relieves the over-fitting problem and improves the generalization ability of neural networks. Specifically, every neuron of the network may be dropped with probability $p$ during the training process.
To implement Dropout in the frequency domain, we propose an approximation method. The probability to be dropped. Assuming that the mean of \( f(x, y) \) is one of the neurons of the time domain feature. Then the Dropout can be written as \( f_d(x, y) = r f(x, y) \), where \( r \) follows the Bernoulli distribution with probability \( 1 - p \) (which means the Dropout rate is \( p \)).

Based on Eq. 2 and the definition of Dropout, we can learn that if we perform Dropout on the time domain, then the corresponding frequency domain feature becomes:

\[
F_{d,\text{real}}(x, y) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} r(x, y) f(x, y) \cos(2\pi \frac{ux}{M} + \frac{vy}{N})
\]

\[
F_{d,\text{imag}}(x, y) = -\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} r(x, y) f(x, y) \sin(2\pi \frac{ux}{M} + \frac{vy}{N})
\]

From Eq. 16 we can learn that it is almost impossible that \( F_{d,\text{real}}(x, y) \) and \( F_{d,\text{imag}}(x, y) \) equal to 0. Thus we can not directly use the regular Dropout on the frequency domain features like Batch Normalization. Moreover, based on Eq. 4 we can know that if we directly set part of neurons in \( F(O_L) \) also become 0. With the network going deep, an increasing proportion of neurons may die, which prevents the network from getting good performance.

To implement Dropout in the frequency domain, we propose an approximation method. The foundation of our approximation method is the observation that performing Dropout on \( f(x, y) \) equals to randomly shrink or amplify \( F_{d,\text{real}}(x, y) \) and \( F_{d,\text{imag}}(x, y) \), because the values of both \( \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \) and \( \sin(2\pi \frac{ux}{M} + \frac{vy}{N}) \) have the same probability that within the ranges of \([-1, 0] \) and \((0, 1] \). Therefore, we have:

\[
F_{d,\text{real}}(x, y) \simeq r_{\text{appr,real}}(x, y) F_{\text{real}}(x, y)
\]

\[
F_{d,\text{imag}}(x, y) \simeq r_{\text{appr,imag}}(x, y) F_{\text{imag}}(x, y)
\]

Based on the analyses above, we make an assumption that \( r_{\text{appr,real}}(x, y) \) and \( r_{\text{appr,imag}}(x, y) \) should not have large deviation from 1, since all elements of the time domain features have the same probability to be dropped. Assuming that the mean of \( f(x, y) \) is \( M \), then the expectation of the mean of \( r(x, y) f(x, y) \) is \( (1 - p)M \). For \( F_{d,\text{real}}(x, y) \), since the upper bound of \( \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \) is 1 while the lower bound is \(-1\), it is easy to learn that \( r_{\text{appr,real}}(x, y) \) has higher probability to lay between \( 1 - p \) and \( 1 + p \). Similarly, \( r_{\text{appr,imag}}(x, y) \) may also lay between \( 1 - p \) and \( 1 + p \).

Therefore, we make \( r_{\text{appr,real}}(x, y) \) and \( r_{\text{appr,imag}}(x, y) \) obey a normal distribution \( N(1, p/2) \). Here we set the mean of the Normal distribution equals to 1 and standard deviation \( p/2 \). Thus the probability that \( r_{\text{appr,real}}(x, y) \) and \( r_{\text{appr,imag}}(x, y) \) lay between \( 1 - p \) and \( 1 + p \) is about 95.4\%.

Notice that we ignore the relationship between \( \cos(2\pi \frac{ux}{M} + \frac{vy}{N}) \) and \( \sin(2\pi \frac{ux}{M} + \frac{vy}{N}) \) to simplify the calculation, thus \( r_{\text{appr,real}}(x, y) \) and \( r_{\text{appr,imag}}(x, y) \) are independent with each other. In practice the proposed approximated Dropout shows good performance in the frequency domain.

### 3.1.4 Leaky ReLU

Currently, rectified linear unit (ReLU) [Dahl et al. 2013] is a prevalent activation function. The form of ReLU is \( f(x) = \max(0, x) \), which is very simple, and may increase the training speed of neural networks because its gradient can be calculated much easier. Leaky ReLU [Maas 2013] is a generalization of ReLU, which can be defined as below:

\[
f(x) = \begin{cases} 
  x & x \geq 0, \\
  ax & x < 0.
\end{cases}
\]

(18)

where \( a \) is a pre-defined constant. In this way, Leaky ReLU may avoid the ‘dead ReLU’ problem, which means a large number of neurons cannot be activated since they have always been set to 0 by using ReLU.

Similar to Dropout, we can easy to learn that doing ReLU or Leaky ReLU on the time domain equals to shrink or amplify the value of both \( F_{\text{real}}(x, y) \) and \( F_{\text{imag}}(x, y) \). However, unlike Dropout, using
ReLU or Leaky ReLU is not a random process, thus we may not introduce the method similar to Eq. (17). In practice, we found that directly applying Leaky ReLU on $F_{\text{real}}(x, y)$ and $F_{\text{imag}}(x, y)$ results in good classification performance. One possible reason for this observation is that Leaky ReLU not only introduces non-linearity into CEMNet, but also avoids setting many neurons to 0.

### 3.1.5 Max Pooling

Max Pooling is an essential element of CNNs, since it serves as a tool for down-sampling and has good performance in many databases and real-world tasks. Unfortunately, Max Pooling cannot work in the frequency domain since complex numbers cannot compare with each other. Therefore, to implement pooling layers of CEMNet, we firstly transfer the input feature maps back to the time domain, then perform Max Pooling and transfer the results back to the frequency domain.

### 3.2 Complex Element-wise Multiplication Network

Based on the analysis of important layers above, we found that we can process real parts and imaginary parts of input features separately for most kinds of layers. Inspired by Guberman [2016] and Trabelsi et al. [2018], we design a two-branches structure of CEMNet to integrate all network layers in the frequency domain.

The basic idea of CEMNet is to introduce two branches (one for the real part and the other for the imaginary part of complex features) in each layer. For instance, the implementation of Element-wise Multiplication Layers (see Eq. 4) can be described as Algorithm 1. We can use a similar method to implement Dropout layers.

<table>
<thead>
<tr>
<th>Algorithm 1</th>
<th>The operations of the two-branches Element-wise Multiplication Layer</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input:</strong></td>
<td>The real part of input feature map $F_{\text{I,real}}^r$, the imaginary part of input feature map $F_{\text{I,imag}}^r$, the real part of weight $F_{\text{W,real}}$, and the imaginary part of weight $F_{\text{W,imag}}$</td>
</tr>
<tr>
<td><strong>Output:</strong></td>
<td>The real part of output feature map $F_{\text{O,real}}$, and the imaginary part of output feature map $F_{\text{O,imag}}$</td>
</tr>
<tr>
<td><strong>Do Weight Fixation on $W$ to update</strong></td>
<td>$F_{\text{W,real}}$ and $F_{\text{W,imag}}$</td>
</tr>
<tr>
<td>$F_{rr} = F_{\text{I,real}}^r \cdot F_{\text{W,real}}$, where $\cdot$ is element-wise production</td>
<td></td>
</tr>
<tr>
<td>$F_{ri} = F_{\text{I,real}}^r \cdot F_{\text{W,imag}}$</td>
<td></td>
</tr>
<tr>
<td>$F_{ir} = F_{\text{I,imag}}^r \cdot F_{\text{W,real}}$</td>
<td></td>
</tr>
<tr>
<td>$F_{ii} = F_{\text{I,imag}}^r \cdot F_{\text{W,imag}}$</td>
<td></td>
</tr>
<tr>
<td>$F_{\text{O,real}} = \text{LeReLU}(\text{BNorm}(F_{rr} + F_{ii}))$</td>
<td></td>
</tr>
<tr>
<td>$F_{\text{O,imag}} = \text{LeReLU}(\text{BNorm}(F_{ri} - F_{ir}))$</td>
<td></td>
</tr>
</tbody>
</table>

At the end of CEMNet, we need to transfer feature maps back to the time domain, flatten them, then feed them into one or more fully connected layers to generate classification results.

### 4 Experimental Results

#### 4.1 Databases and Computation Platform

In this paper, we apply two widely used databases to evaluate the proposed CEMNet, i.e., MNIST and CIFAR-10. MNIST database [LeCun et al. 1998] is a hand-written digits database that contains 60,000 training images and 10,000 test images, and the images are 28-by-28 in size. All images are grey-scale and only contain one digit. CIFAR-10 database [Krizhevsky et al. 2014] is widely used in image classification tasks. It contains 50,000 32-by-32 RGB images for training and 10,000 images for validation, and all images are divided into 10 classes. We implement the proposed CEMNet on Tensorflow 2.5 [Abadi et al. 2015] platform, and our computation platform includes Intel Xeon 4108 CPU, 128 GB memory, and two Tesla V100 GPUs.

---

1. The url of our source codes: https://github.com/mowangphy88/CEMNet
4.2 MNIST Experiments

The baseline CNN structure of MNIST experiments is based on LeNet-5 [Lecun et al. 1998]. Comparing with the original LeNet-5, the feature map size of the second convolution layer of our network is set to $14 \times 14$ instead of $10 \times 10$ by using zero-padding, thus after the second down-sampling, the feature map size becomes $7 \times 7$. The activation function of each layer is Leaky-ReLU with $\alpha = 0.2$. Moreover, we add Batch Normalization and Dropout after each convolution layer and fully-connected layer. Based on the CNN structure, we build the corresponding CEMNet to test the performance in the frequency domain.

During the training process of CEMNet, we use RMSProp as the optimizer. The batch-size is set to 100, and the network should be trained for 1000 epochs. We use a cosine decay learning rate schedule with an initial learning rate $= 0.001$ and a minimum learning rate $= 0.00001$. Notice that we do not apply any data augmentation methods during the training process.

We select several state-of-the-art frequency domain neural network methods as baselines to compare with CEMNet. Moreover, to show the importance of the proposed methods, we also include ablation studies. The experimental results of MNIST are included in Table 1 and we can learn that Weight Fixation, Batch Normalization, and Dropout work well in the frequency domain. Generally speaking, CEMNet has a better performance compared with previous DFT based methods, and at least comparable with its CNN counterpart. Moreover, the CEMNet has much less number of operations of the forward pass than the corresponding CNN.

4.3 CIFAR-10 Experiments

The baseline CNN structure of CIFAR-10 experiments is based-on VGG-16 [Simonyan and Zisserman 2014] framework, which contains 5 blocks. Each block contains one or more convolution layers and ends with a sub-sampling layer, and the number of feature maps of convolution layers in each block is set to 64, 128, 256, 512, 512. The network ends with one or more fully-connected layers. The activation function of each layer is Leaky-ReLU with $\alpha = 0.2$. We consider 2 scales of CNNs:

(1) Small scale CNN: each block contains one convolution layer, and the network ends with one fully-connected layer with 512 neurons.

(2) Large scale CNN: the number of convolution layers in each block is set to 2, 2, 2, 3, 3, and the network ends with one fully-connected layer with 512 neurons.

Notice that for both CNNs we also apply Batch Normalization and Dropout after each convolution layer and fully-connected layer. We build the corresponding CEMNets based on the above-mentioned two CNN structures.

During the training process of CEMNets with CIFAR-10 database, we use RMSProp as the optimizer. The batch-size is set to 100, and the network should be trained for 500 epochs. We use a cosine decay learning rate schedule with an initial learning rate $= 0.001$ and a minimum learning rate $= 0.00001$. Data augmentation methods are also not applied during the training process.
Similar to MNIST, we compare the proposed CEMNets to previous methods as well as their CNN counterparts. We also do ablation studies for the small scale CEMNet. Table 2 provides experimental results on CIFAR-10, which also show the advantages of the proposed method.

From experiments of CIFAR-10 we can learn that the Small CEMNet has comparable performance to the corresponding Small CNN, but the performance gap between the Large CEMNet and Large CNN is relatively large. One potential reason for this situation is the Weight Fixation method. Even though the Weight Fixation reduces the number of free parameters and alleviates the problem of over-fitting, it discards a large amount of gradient information. Therefore, with the network going deep, the problem of gradient vanishing may happen much easier, which negatively impacts on the classification performance.

5 Conclusion and Future Works

In this paper, we propose a novel neural network model, namely CEMNet, that can be trained in the frequency domain. Based on the Cross-Correlation Theorem, we design the element-wise multiplication layer to remove all convolution operations from CNNs and reduce the computation complexity. To alleviate the problem of over-fitting, we introduce the Weight Fixation mechanism. Moreover, we theoretically analyze the working behavior of Batch Normalization, Leaky ReLU, and Dropout in the frequency domain, and introduce their counterparts into CEMNet. Also, to deal with complex inputs brought by DFT, we design a two-branches network structure for CEMNet. Experimental results show that CEMNets achieve better performance on MNIST and CIFAR-10 compared with previous DFT based methods.

This research still remains some open problems that should be solved in the future. The first problem is the network performance of large models. Based on our analyses in Section 4, we can learn that our Weight Fixation may result in gradient vanishing on large models and brings about negative influences on classification performance. Thus we may need to update the Weight Fixation mechanism and consider to introduce residual connections to deal with this problem. Secondly, based on Section 5 our Leaky ReLU and Dropout work in the frequency domain are not totally equal to their counterparts in the time domain, which may also lead to the performance gap between CEMNets and corresponding CNNs. Thirdly, our method needs to repeatedly transfer data between the time domain and frequency domain, which may slow down the learning speed. We will consider to speed up our method by removing DFT operations during the training stage.

Checklist

The checklist follows the references. Please read the checklist guidelines carefully for information on how to answer these questions. For each question, change the default [TODO] to [Yes], [No], or [N/A]. You are strongly encouraged to include a justification to your answer, either by referencing the appropriate section of your paper or providing a brief inline description. For example:

- Did you include the license to the code and datasets? [Yes] See Section ??.
- Did you include the license to the code and datasets? [No] The code and the data are proprietary.
- Did you include the license to the code and datasets? [N/A]

Please do not modify the questions and only use the provided macros for your answers. Note that the Checklist section does not count towards the page limit. In your paper, please delete this instructions block and only keep the Checklist section heading above along with the questions/answers below.

1. For all authors...
   a. Do the main claims made in the abstract and introduction accurately reflect the paper’s contributions and scope? [Yes]
   b. Did you describe the limitations of your work? [Yes]
   c. Did you discuss any potential negative societal impacts of your work? [N/A]
   d. Have you read the ethics review guidelines and ensured that your paper conforms to them? [Yes]
2. If you are including theoretical results...
   (a) Did you state the full set of assumptions of all theoretical results? [N/A]
   (b) Did you include complete proofs of all theoretical results? [N/A]

3. If you ran experiments...
   (a) Did you include the code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL)? [Yes]
   (b) Did you specify all the training details (e.g., data splits, hyperparameters, how they were chosen)? [Yes]
   (c) Did you report error bars (e.g., with respect to the random seed after running experiments multiple times)? [N/A]
   (d) Did you include the total amount of compute and the type of resources used (e.g., type of GPUs, internal cluster, or cloud provider)? [Yes]

4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets...
   (a) If your work uses existing assets, did you cite the creators? [Yes]
   (b) Did you mention the license of the assets? [N/A]
   (c) Did you include any new assets either in the supplemental material or as a URL? [N/A]
   (d) Did you discuss whether and how consent was obtained from people whose data you’re using/curating? [N/A]
   (e) Did you discuss whether the data you are using/curating contains personally identifiable information or offensive content? [N/A]

5. If you used crowdsourcing or conducted research with human subjects...
   (a) Did you include the full text of instructions given to participants and screenshots, if applicable? [N/A]
   (b) Did you describe any potential participant risks, with links to Institutional Review Board (IRB) approvals, if applicable? [N/A]
   (c) Did you include the estimated hourly wage paid to participants and the total amount spent on participant compensation? [N/A]
