Keywords: MFRTB method, TB approximation,

A non-perturbative relativistic tight-binding (TB) approximation method applicable to crystalline material immersed in magnetic field was developed in 2015 [1]. To apply this method to any material in magnetic field, the electronic structure of the material in absence of magnetic field must be calculated. In this study, we present the relativistic TB approximation method for graphene in zero magnetic field. The Hamiltonian and overlap matrix is constructed considering the nearest neighbouring atomic interactions between the $s$ and $p$ valence orbitals, where the relativistic hopping and overlap integrals are calculated using the relativistic version of the Slater-Koster table. The method of constructing the Hamiltonian and overlap matrix and the resulting energy-band structure of graphene in the first Brillouin zone is presented in this paper. It is found that there is an appearance of a small band-gap at the $K$ points (also known as the spin-orbit gap) due to the relativistic effect, whose magnitude is 25 $\mu$eV.

1 Introduction

The popularity in graphene research mainly stems from its unique and fascinating electronic [2, 3, 4, 5] and magnetic properties [5, 6, 7] and also due to the promise of potential applications and emergence of a new paradigm of relativistic-condensed matter physics [8]. Some of these physical properties are: it’s minimum conductance never falls below the value corresponding to the smallest quantum unit of conductance even when the charge carrier concentrations tends to zero [2], tunable conductivity in twisted monolayer-bilayer graphene system [5], insulating behaviour at low temperatures [5], half-integer quantum hall effect [7], unconventional magnetic oscillations [9] and strong orbital diamagnetism [10]. The anomalous electronic properties of graphene arises from its characteristic band structure which is due to the effectively massless charge carriers with relativistic behaviour known as Dirac fermions at energies near Fermi level where the conical valance band and conduction band meet at a single point in momentum space called the Dirac points.

Because of these physical properties of graphene it is desirable to investigate into a first principle calculation method that takes into account both the relativistic effect and magnetic field. There are several studies where the electronic structure is calculated with non-relativistic tight binding model [11, 12] and a large number of these studies have been without considering the overlap integral [12, 13, 4]. There also exists a lot of credible relativistic calculation methods of electronic structures in absence of magnetic field [14, 15, 16] that have been successfully applied to f-electron materials [17], but the electronic structure calculation method that can deal with magnetic field and relativistic effects simultaneously is desired for the study.

In 2015 a Non-perturbative Tight-Binding (TB) method called the magnetic-field-containing relativistic tight-binding approximation method (MFRTB method) was developed incorporating both the relativistic effects and magnetic field in the same footing and was applied to silicon crystal immersed in magnetic field [1]. The MFRTB method was developed to alternatively describe the oscillatory behaviour of the magnetization as a function of magnetic field (the de Haas-van Alphen effect) from a view point of the first-principle calculation. The MFRTB method was successfully able to calculate the relativistic energy band structures of silicon in an external magnetic field [1] that explained the suppression of softening in the elastic constant of boron-doped silicon in an external magnetic field, and also revisit the dHvA effect in a first-principle way [15]. This method also presents the relativistic version of the Slater-Koster table in which the relativistic hopping integrals are explicitly expressed in terms of relativistic TB parameters for the interactions corresponding to $2s$ and $2p$ orbitals.
In order to apply the MFRTB method to graphene in magnetic field, the magnetic hopping integrals must be expressed in terms of relativistic hopping integrals for zero magnetic field and magnetic field-dependent phase factor. So as an initial step, we need to formulate a relativistic TB approximation method for graphene in zero magnetic field. In this paper a relativistic TB model for graphene in absence of magnetic field is formulated starting from the Dirac equation for an electron in a periodic potential. Then the Dirac hamiltonian matrix and overlap matrix of the system is constructed utilizing the relativistic Slater-Koster table considering the nearest neighbour interactions between 2s and 2p orbitals. Then by solving the general eigen value equation for different \( \mathbf{k} \) points in the first Brillouin zone using computer program (Python), the relativistic electronic structure of graphene is produced. Our results have shown an appearance of a small band gap (25 \( \mu \)eV) at the Dirac points due to the relativistic effect (spin-orbit coupling), which is in excellent agreement with the first principle calculation results using the linearized augmented plane-wave method incorporating the spin-orbit coupling [19].

2 Relativistic TB theory for graphene lattice in zero magnetic field

![Figure 1: Illustration of honeycomb lattice and unit cell of graphene](image)

Considering the two atoms of the unit cells of the honeycomb lattice, we proceed to establish the equations for the hamiltonian matrix elements and the overlap matrix elements of the system. We represent the two atoms of the unit cell as ‘A’ and ‘B’.

2.1 For lattice site ‘A’

The Dirac equation for an electron at lattice site ‘A’ is

\[
\hat{H}_A \Psi_{\alpha, \mathbf{k}}(\mathbf{r}) = E(\mathbf{k}) \Psi_{\alpha, \mathbf{k}}(\mathbf{r}), \tag{1}
\]

with the atomic hamiltonian at site ‘A’ as

\[
\hat{H}_A = c \mathbf{\bar{\alpha}} \cdot \mathbf{p} + \beta mc^2 + V_A(\mathbf{r} - \mathbf{R}_n), \tag{2}
\]

where \( c \) denote the velocity of light, \( m \) denote the electron rest mass, \( \mathbf{\bar{\alpha}} = (\alpha_x, \alpha_y, \alpha_z) \), \( \beta \) stands for the usual 4 \( \times \) 4 matrices [20]. \( V_A(\mathbf{r} - \mathbf{R}_n) \) represents the Coulomb potential due to the nucleus of atom at site ‘A’ located at \( \mathbf{R}_n \), the subscripts \( \alpha \) and \( \mathbf{k} \) of the eigen function \( \Psi_{\alpha, \mathbf{k}}(\mathbf{r}) \) represents the band index and crystal momentum respectively.

Expanding \( \Psi_{\alpha, \mathbf{k}}(\mathbf{r}) \) by using the Bloch sum of relativistic atomic orbital \( \phi_{nlJM}^A(\mathbf{r}) \) of atom at ‘A’ as the basis function, we have

\[
\Psi_{\alpha, \mathbf{k}}(\mathbf{r}) = \sum_{nlJM} C_{nlJM}^A \phi_{nlJM}^A(\mathbf{r}), \tag{3}
\]

where \( C_{nlJM}^A \) is the expansion coefficient and \( \phi_{nlJM}^A(\mathbf{r}) \) denote the Bloch sum which is written as

\[
\phi_{nlJM}^A(\mathbf{r}) = \frac{1}{\sqrt{N}} \sum_{\mathbf{R}_n} e^{i\mathbf{k} \cdot \mathbf{R}_n} \phi_{nlJM}(\mathbf{r} - \mathbf{R}_n). \tag{4}
\]

In Eq. (1) multiplying by \( \phi_{nlJM}^A(\mathbf{F} - \mathbf{R}_n') \) where \( \mathbf{R}_n' \neq \mathbf{R}_n, A' \neq A \) and integrating and denoting the hopping and overlap integrals by \( \tau_{nlJM}^{A'JM}, \phi_{nlJM}(\mathbf{r} - \mathbf{R}_n - \mathbf{R}_n') \) respectively, we define the hamiltonian and overlap matrix elements as

\[
\mathbf{H}_{nlJM}^{A'JM'}(\mathbf{K}) = \sum_{\mathbf{R}_n} e^{i\mathbf{K} \cdot \mathbf{R}_n} \tau_{nlJM}^{A'JM'}(\mathbf{R}_n - \mathbf{R}_n'), \tag{6}
\]

and,

\[
\mathbf{S}_{nlJM}^{A'JM'}(\mathbf{K}) = \sum_{\mathbf{R}_n} e^{i\mathbf{K} \cdot \mathbf{R}_n} \phi_{nlJM}^{A'JM'}(\mathbf{R}_n - \mathbf{R}_n'). \tag{7}
\]

So Eq. (1) becomes

\[
\sum_{nlJM} \mathbf{H}_{nlJM}^{A'JM'}(\mathbf{K}) C_{nlJM}^{A'JM'}(\mathbf{K}) = E(\mathbf{K}) \sum_{nlJM} \mathbf{S}_{nlJM}^{A'JM'}(\mathbf{K}) C_{nlJM}^{A'JM'}(\mathbf{K}). \tag{8}
\]

After evaluating the relativistic hopping and overlap integrals when the lattice site is considered to be at the origin \( (\mathbf{R}_n, d_x, d_y) \) and when the lattice site is considered to be elsewhere \( (\mathbf{R}_n \neq 0, d_x \neq d_y) \) and by neglecting the three center integral, we get the matrix elements of the hamiltonian and overlap Eq. (6) and Eq. (7) as:
\[ H_{n'v',J'M',nlJM}^{A,A}(\vec{R}) = \]
\[ (\varepsilon_{nlJ}^{A} + \Delta_{nlJM}^{A})\delta_{n'v',J'M',nlJM}\delta_{i,j} + \sum_{\vec{R}_{n}} e^{i\vec{k} \cdot \vec{R}_{n}} (1 - \delta_{\vec{R}_{n},0}\delta_{i,j}) t_{n'v',J'M',nlJM}^{new,A,A}(\vec{R}_{n}), \]
\[ \text{with} \]
\[ t_{n'v',J'M',nlJM}^{new,A,A}(\vec{R}_{n}) = \]
\[ \frac{1}{2}(\varepsilon_{nlJ}^{A} + \varepsilon_{n'v',J'}^{A})s_{n'v',J'M',nlJM}^{A}(\vec{r} - \vec{R}_{n}) + \int \phi_{n'v',J'M'}^{A}^{\ast}(\vec{r}) \left( V_{A}(\vec{r}) + V_{A}(\vec{r} - \vec{R}_{n}) \right) \]
\[ \times \phi_{nlJM}^{A}(\vec{r} - \vec{R}_{n})d^{3}\vec{r}, \]
\[ \text{and} \]
\[ s_{n'v',J'M',nlJM}^{A}(\vec{R}_{n}) = \]
\[ \int \phi_{n'v',J'M'}^{A}(\vec{r}) \phi_{nlJM}^{A}(\vec{r} - \vec{R}_{n})d^{3}\vec{r}. \]

In Eq. (9) \[ \Delta_{nlJM}^{A} \] denotes the crystal field energy due to the influence of other lattice sites on site ‘A’ written as:
\[ \Delta_{nlJM}^{A} = \int \phi_{n'v',J'M'}^{A}(\vec{r}) \sum_{\vec{R}_{m} \neq \vec{R}_{n}} \sum_{A' \neq A} V_{A}(\vec{r} - \vec{R}_{m}) \]
\[ \times \phi_{nlJM}^{A}(\vec{r} - \vec{R}_{m})d^{3}\vec{r}. \]

2.2 For lattice site ‘B’

Similarly for Lattice site ‘B’ located at \( \vec{R}_{n} + \vec{d}_{i} \) where \( \vec{d}_{i} \) is the position vector from ‘A’ to ‘B’, we can formulate the hamiltonian and overlap matrix elements as:
\[ H_{n'v',J'M',nlJM}^{B,B}(\vec{R}) = \]
\[ (\varepsilon_{n'v',J'M',nlJM}^{B} + \Delta_{nlJM}^{B})\delta_{n'v',J'M',nlJM}\delta_{i,j} + \sum_{\vec{R}_{n}} e^{i\vec{k} \cdot (\vec{R}_{n} + \vec{d}_{i})} (1 - \delta_{\vec{R}_{n},0}\delta_{i,j}) t_{n'v',J'M',nlJM}^{new,B,B}(\vec{R}_{n}), \]
\[ \text{with} \]
\[ t_{n'v',J'M',nlJM}^{new,B,B}(\vec{R}_{n}) = \]
\[ \frac{1}{2}(\varepsilon_{n'v',J'}^{B} + \varepsilon_{nlJ}^{B})s_{n'v',J'M',nlJM}^{B}(\vec{r} - \vec{R}_{n} - \vec{d}_{i} + \vec{d}_{j}) + \int \phi_{n'v',J'M'}^{B}(\vec{r}) \left( V_{B}(\vec{r}) + V_{B}(\vec{r} - \vec{R}_{n} - \vec{d}_{i} + \vec{d}_{j}) \right) \]
\[ \times \phi_{nlJM}^{B}(\vec{r} - \vec{R}_{n} - \vec{d}_{i} + \vec{d}_{j})d^{3}\vec{r}, \]
\[ \text{and} \]
\[ s_{n'v',J'M',nlJM}^{B}(\vec{R}_{n}) = \]
\[ \delta_{n'v',J'M',nlJM}\delta_{i,j} + \sum_{\vec{R}_{n}} e^{i\vec{k} \cdot (\vec{R}_{n} + \vec{d}_{i})} (1 - \delta_{\vec{R}_{n},0}\delta_{i,j}) \]
\[ \times s_{n'v',J'M',nlJM}^{new,B,B}(\vec{R}_{n} - \vec{d}_{i} + \vec{d}_{j}). \]
\[
\sum_{nlJM} [(\varepsilon_{nlJ} + \Delta \varepsilon_{nlJM}) \delta_{n'J'M',nlJM} + \sum_{\vec{R}_n} \sum_{i=1}^{3} e^{i\vec{k}\cdot\vec{R}_n + i\vec{d}_j} (1 - \delta_{\vec{R}_n,0}\delta_{i,j})]
\]

\[
t_{n'J'M',nlJM}^{\text{new}}(\vec{R}_n - \vec{d}_i + \vec{d}_j)C_{nIJM,k} - E(\vec{k})[\delta_{n'J'M',nlIJM}\delta_{i,j}]
\]

\[
+ \sum_{\vec{R}_n} \sum_{i=1}^{3} e^{i\vec{k}\cdot(\vec{R}_n + \vec{d}_i)} (1 - \delta_{\vec{R}_n,0}\delta_{i,j})
\]

\[
x s_{n'J'M',nlJM}^{\text{new}}(\vec{R}_n - \vec{d}_i + \vec{d}_j)C_{nIJM,k}
\]

(21)

Eq. (21) is called the simultaneous equation which needs to be solved to obtain the energy eigenvalue \(E(\vec{k})\).

### 3 Method

#### 3.1 Construction of Hamiltonian and overlap matrix of the system

In our calculations, we have considered the atomic states of valance orbitals of carbon atom so the interactions take place among the following 8 atomic states: \((2,0,\frac{1}{2},\frac{1}{2}), (2,0,\frac{1}{2},-\frac{1}{2}), (2,1,\frac{1}{2},\frac{1}{2}), (2,1,\frac{1}{2},-\frac{1}{2}), (2,1,\frac{1}{2},\frac{1}{2}), (2,1,\frac{1}{2},-\frac{1}{2}), (2,1,\frac{1}{2},\frac{1}{2})(2,1,\frac{1}{2},-\frac{1}{2})\).

We can now construct the Hamiltonian and overlap matrix using Eq. (19) and Eq. (20). To obtain the numerical values of \(t_{n'J'M',nlIJM}^{\text{new}}(\vec{R}_n - \vec{d}_i + \vec{d}_j)\) and \(s_{n'J'M',nlIJM}^{\text{new}}(\vec{R}_n - \vec{d}_i + \vec{d}_j)\) we have used the relativistic version of the Slater-Koster table 1 to express hopping and overlap integrals in terms of the TB parameters \(K_i(n'J',nlJ_{[M]}\) and \(S_i(n'J',nlJ_{[M]}\) and then solving Eq. (19) and Eq. (11). Since the crystal field energy is very small compared to the atomic spectrum, we have neglected \(\Delta \varepsilon_{nlJM}\) and used the atomic spectrum \(\varepsilon_{nlJ}\) that is calculated using density functional theory 21,22 based on local density approximation 23. The numerical values of the term \(\varepsilon_{nlJ} + \Delta \varepsilon_{nlJM}\) are listed in Table 1. The numerical values of the TB parameters for the 8 atomic states of the nearest neighbouring atoms of graphene \(K_i(n'J',nlJ_{[M]}\) and \(S_i(n'J',nlJ_{[M]}\) has been calculated 23 which are listed in Table 2.

#### 3.2 Electronic structure calculation

By utilizing the values from Table 1 and Table 2 and using Eq. (19) and Eq. (20) for the 8 atomic states at sites ‘A’, ‘B’, and ‘A’, ‘B’, a \(16 \times 16\) hamiltonian and overlap matrix is constructed. The first term of Eq. (19) and Eq. (20) vanishes for the non-diagonal diagonal elements (since \(n'J'M' \neq nlJM\) and \(i \neq j\), the second term vanishes for the diagonal elements (since \(i = j\) and \(\vec{R}_n = 0\)). The tabular representation of thus-constructed hamiltonian and overlap matrix is shown in the Appendix section.

</tbody>
</table>
It can be shown that the position coordinates of the high symmetry points are as follows:

\[ \Gamma = (0, 0) \]
\[ K = \left( \frac{2\pi}{a\sqrt{3}}, \frac{2\pi}{3a} \right) \]
\[ M = \left( \frac{2\pi}{a\sqrt{3}}, 0 \right) \] (22)

After we have constructed the Hamiltonian and overlap matrix of graphene, we can solve the general eigenvalue Eq. (8) to get the energy eigenvalue \( E(\mathbf{k}) \), and since the energy eigenvalue is a function of \( \mathbf{k} \) we need to solve the eigenvalue equation along the high symmetry points in the \( \mathbf{k} \)-space along a closed contour to obtain a continuous electronic band structure. For our calculation, the contour of \( K - \Gamma - M - K \) is chosen.

### 3.3 Computing Algorithm

The necessary computations were done in Python 3.8.5 utilizing python libraries. The following libraries were used in our calculation. “linalg” was imported from the “scipy” library to carry out the eigenvalue problem calculation. “numpy” and “math” libraries were used to create matrix and to perform mathematical calculations. “Matplotlib” was used to generate the plots of energy eigenvalues with respect to \( \mathbf{k} \) points.

After assigning the variables for each matrix elements of the top right 8 x 8 submatrices of the hamiltonian (Table 3) and overlap matrix (Table 4) and the diagonal elements, we constructed the matrices using the command “numpy.array”. Then the general eigenvalue equation was solved by utilizing the linear algebra package “linalg” and the eigen values are stored in a variable. 

```
cmd-line: lambda=linalg.eigh(H,S,lower=False)
```

In order to calculate the eigenvalues along the contour defined above, each path from \( K - \Gamma - M - K \) was divided into 100 equal intervals including the starting and the end points using the command “numpy.linspace”. A list of equally spaced numbers from the coordinates of \( K \) to coordinates of \( \Gamma \), from coordinates of \( \Gamma \) to coordinates of \( M \) and from coordinates of \( M \) back to coordinates of \( K \) were generated as \( \mathbf{k} \) points representing the X-axis. Then by using the “for” loop, the eigenvalue equation was solved for each of the \( k \) points in the interval. The corresponding eigenvalues were stored in a new list, which was plotted against the \( k \) points interval to get the desired electronic band structure. The band gap value was calculated by taking the energy difference between the highest occupied and the lowest unoccupied state at the \( \mathbf{k} \) point corresponding to the coordinates of symmetry point \( K \).

### 4 Result

The obtained band gap energy at the \( K \) point was 2.5832076860657534 \( \times 10^{-5} \) eV whose value is in close agreement with the value shown by the first-principle calculations considering spin-orbit interaction done by the FLAPW method [19].

The figures below shows the energy band diagrams obtained from the above mentioned algorithm.
The energy diagram obtained from the calculation along the closed contour $K - \Gamma - M - K$ is shown in Fig. (4a) and Fig. (4b) below. The reference data using the FLAPW method is shown in Fig. (4c).

Figure 4: Relativistic energy bands structure of graphene.

4.1 Remarks and conclusion

(i) We have developed the relativistic tight-binding model that enables us to calculate the electronic structure and electronic properties of graphene, taking into account the relativistic effects by treating the Dirac equation for electron moving in a periodic potential.

(ii) The formulation is accomplished in the orthodox coordinate representation.

(iii) Using the general expressions to calculate the
Hamiltonian and overlap matrix, we have constructed the Dirac Hamiltonian and overlap matrix of the system considering the nearest neighbouring atomic interactions.

(iv) By solving the general eigenvalue equation for different $\vec{k}$ points, we have successfully revealed the relativistic electronic band structure of graphene.

(v) Appearance of a small energy band gap due to the spin-orbit interaction, along with the energy band-gap value has been shown.

The validity of the MFRTB method has been successfully tested and the magnetic field effects can also be incorporated into the present model by utilizing magnetic Bloch theorem and approximating the magnetic hopping integrals as the relativistic hopping integrals multiplied by the magnetic-field-dependent phase factor, which would be our future works. In conclusion, this is a coherent relativistic tight-binding model that can be applied to accurately predict the relativistic effects for various systems.
