TOTAL DOMINATION NUMBER OF MIDDLE GRAPHS

FARSHAD KAZEMNEJAD, BEHNAZ PAHLAVSAY, ELISA PALEZZATO,
AND MICHELE TORIELLI

Abstract. A total dominating set of a graph $G$ with no isolated vertices is a subset $S$ of the vertex set such that every vertex of $G$ is adjacent to a vertex in $S$. The total domination number of $G$ is the minimum cardinality of a total dominating set of $G$. In this paper, we study the total domination number of middle graphs. Indeed, we obtain tight bounds for this number in terms of the order of the graph $G$. We also compute the total domination number of the middle graph of some known families of graphs explicitly. Moreover, some Nordhaus-Gaddum-like relations are presented for the total domination number of middle graphs.

Keywords: Total domination number, Middle graph, Nordhaus-Gaddum-like relation.

1. Introduction

The concept of total domination in graph theory was first introduced by Cockayne, Dawes and Hedetniemi in [3] and it has been studied extensively by many researchers in the last years, see for example [5], [6], [7], [13], [8], [10], [12] and [14]. The literature on this subject has been surveyed and detailed in the recent book [7]. We refer to [2] as a general reference on graph theory.

Let $G$ be a graph with the vertex set $V(G)$ of order $n$ and the edge set $E(G)$ of size $m$. The open neighborhood and the closed neighborhood of a vertex $v \in V(G)$ are $N_G(v) = \{ u \in V(G) \mid uv \in E(G) \}$ and $N_G[v] = N_G(v) \cup \{v\}$, respectively. For a connected graph $G$, the degree of a vertex $v$ is defined as $d_G(v) = |N_G(v)|$. The distance $d_G(v, w)$ in $G$ of two vertices $v, w \in V(G)$ is the length of the shortest path connecting $v$ and $w$. The diameter $\text{diam}(G)$ of $G$ is the shortest distance between any two vertices in $G$. A dominating set of a graph $G$ is a set $S \subseteq V(G)$ such that $N_G[v] \cap S \neq \emptyset$, for any vertex $v \in V(G)$. The domination number of $G$ is the minimum cardinality of a dominating set of $G$ and is denoted by $\gamma(G)$.

Definition 1.1. Let $G$ be a graph with no isolated vertices. A total dominating set of $G$ is a set $S \subseteq V(G)$ such that $N_G(v) \cap S \neq \emptyset$, where
for any vertex \( v \in V(G) \). The total domination number of \( G \) is the minimum cardinality of a total dominating set of \( G \) and is denoted by \( \gamma_t(G) \).

**Example 1.2.** Consider the path \( P_3 \) with vertex set \( \{v_1, v_2, v_3\} \) and edge set \( \{v_1v_2, v_2v_3\} \). Then the set \( S = \{v_1, v_2\} \) is a total dominating set of \( P_3 \).

For any non-empty \( S \subseteq V(G) \), we denote by \( G[S] \) the subgraph of \( G \) induced on \( S \). For any \( v \in V(G) \), we denote by \( G \setminus v \) the subgraph of \( G \) induced on \( V(G) \setminus \{v\} \).

The complement \( \overline{G} \) of \( G \) is a graph with vertex set \( V(G) \) such that for every two vertices \( v \) and \( w \), \( vw \in E(G) \) if and only if \( vw \notin E(G) \).

The line graph of \( G \), denoted by \( L(G) \), is the graph with vertex set \( E(G) \), where vertices \( x \) and \( y \) are adjacent in \( L(G) \) if and only if edges \( x \) and \( y \) share a common vertex in \( G \).

In [4], the authors introduced the notion of the middle graph \( M(G) \) of \( G \) as an intersection graph on \( V(G) \).

**Definition 1.3.** The middle graph \( M(G) \) of a graph \( G = (V, E) \) is the graph whose vertex set is \( V(G) \cup E(G) \) and two vertices \( x, y \) in the vertex set of \( M(G) \) are adjacent in \( M(G) \) in case one the following holds:

1. \( x, y \) are in \( E(G) \) and \( x, y \) are adjacent in \( G \).
2. \( x \) is in \( V(G) \), \( y \) is in \( E(G) \), and \( x, y \) are incident in \( G \).

**Example 1.4.** Consider the graph \( P_3 \), then the middle graph \( M(P_3) \) is the one in Figure 1.

![Figure 1. The middle graph \( M(P_3) \)](image)

It is obvious that \( M(G) \) contains the line graph \( L(G) \) as induced subgraph, and that if \( G \) is a graph of order \( n \) and size \( m \), then \( M(G) \) is a graph of order \( n + m \) and size \( 2m + |E(L(G))| \) which is obtained by subdividing each edge of \( G \) exactly once and joining all the adjacent edges of \( G \) in \( M(G) \).

In order to avoid confusion throughout the paper, we fix a “standard” notation for the vertex set and the edge set of \( M(G) \). Assume \( V(G) = \{v_1, v_2, \ldots, v_n\} \), then we set \( V(M(G)) = V(G) \cup M \), where \( M = \{m_{ij} \mid v_iv_j \in E(G)\} \) and \( E(M(G)) = \{v_im_{ij}, v_jm_{ij} \mid v_iv_j \in E(G)\} \cup E(L(G)) \).

In this article, we continue our study from [9] on domination of middle graphs. The paper proceeds as follows. In Section 2, we describe explicitly the total domination number of the middle graph of several
known families of graphs and we present some upper and lower bounds for $\gamma_t(M(G))$ in terms of the order of the graph $G$. In Section 3, we describe bounds for the total domination number of the middle graph of trees. In Section 4, we obtain the same type of results for $\gamma_t(M(G \circ K_1))$, $\gamma_t(M(G \circ P_2))$ and $\gamma_t(M(G + K_p))$. Finally, in the last Section, we present some Nordhaus-Gaddum like relations for the total domination number of middle graphs.

2. Middle graph of known graphs and their total domination number

We start our study on total domination with two key Lemmas.

Lemma 2.1. Let $G$ be a connected graph of order $n \geq 3$ and $S$ a total dominating set of $M(G)$. Then there exists $S' \subseteq E(G)$ a total dominating set of $M(G)$ with $|S'| \leq |S|$.

Proof. If $S \subseteq E(G)$, then take $S' = S$. On the other hand, assume that there exists $v \in S \cap V(G)$. If all edges adjacent to $v$ are already in $S$, then take $S_1 = S \setminus \{v\}$. Otherwise, let $e \in E(G) \setminus S$ be an edge adjacent to $v$. Then consider $S_1 = (S \cup \{e\}) \setminus \{v\}$. Since $S$ is finite, then this process terminates after a finite number of steps, and hence we obtain the described $S'$.

Lemma 2.2. Let $G$ be a connected graph of order $n \geq 2$ and $v \in V(G)$ a vertex not adjacent to any vertex of degree 1. Then

$$\gamma_t(M(G \setminus v)) \leq \gamma_t(M(G)) \leq \gamma_t(M(G \setminus v)) + 1.$$ 

Proof. Let $S$ be a total dominating set of $M(G \setminus v)$. This implies that for every $w \in N_G(v)$, $w \in S$ or there exists an edge of the form $vw_0 \in E(G \setminus v)$ such that $vw_0 \in S$. As a consequence, $S \cup \{vw\}$ is a total dominating set of $M(G)$, for any $w \in N_G(v)$, and hence

$$\gamma_t(M(G)) \leq \gamma_t(M(G \setminus v)) + 1.$$ 

On the other hand, let $S$ be a minimal total dominating set of $M(G)$. By Lemma 2.1, we can assume that $S \subseteq E(G)$. Consider $S_v = N_{M(G)}(v) \cap S$. Since $S$ is a minimal total dominating set, $|S_v| \geq 1.$ Assume $S_v = \{e_1, \ldots, e_k\}$. For any $1 \leq i \leq k$, $e_i$ is an edge of $G$ of the form $w_i v$. By the construction on $v$, $N_{M(G)}(w_1) = \{e_1, e_{11}, \ldots, e_{1p}\}$ with $p \geq 1$, for some $e_{ij} \in E(G \setminus v)$. If $S \cap \{e_{11}, \ldots, e_{1p}\} \neq \emptyset$, then consider $S_1 = (S \setminus e_1) \cup \{w_1\}$, otherwise $S_1 = (S \setminus e_{11}) \cup \{e_{11}\}$. By applying the same construction for each $e_i$, we obtain $S_k$ a total dominating set of $M(G \setminus v)$ with $|S_k| = |S|$, and hence $\gamma_t(M(G \setminus v)) \leq \gamma_t(M(G))$. 

We are now ready to describe explicitly the total dominating number of the middle graph of several known families of graphs.

Proposition 2.3. For any star graph $K_{1,n}$ on $n + 1$ vertices, with $n \geq 2$, we have

$$\gamma_t(M(K_{1,n})) = n.$$
Proof. To fix the notation, assume \( V(K_{1,n}) = \{v_0, v_1, \ldots, v_n\} \) and \( E(K_{1,n}) = \{v_0v_1, v_0v_2, \ldots, v_0v_n\} \). Then \( V(M(K_{1,n})) = V(K_{1,n}) \cup \mathcal{M} \), where \( \mathcal{M} = \{m_i \mid 1 \leq i \leq n\} \).

If \( S = \mathcal{M} \), then \( S \) is a total dominating set of \( M(K_{1,n}) \) with \( |S| = n \), and hence \( \gamma_t(M(K_{1,n})) \leq n \). On the other hand, using \([9, \text{Proposition 3.1}]\), \( n = \gamma_t(M(K_{1,n})) \leq \gamma_t(M(K_{1,n})) \). \( \square \)

**Definition 2.4.** A double star graph \( S_{1,n,n} \) is obtained from the star graph \( K_{1,n} \) by replacing every edge with a path of length 2.

**Proposition 2.5.** For any double star graph \( S_{1,n,n} \) on \( 2n + 1 \) vertices, with \( n \geq 1 \), we have

\[
\gamma_t(M(S_{1,n,n})) = 2n.
\]

**Proof.** To fix the notation, assume \( V(S_{1,n,n}) = \{v_0, v_1, \ldots, v_{2n}\} \) and \( E(S_{1,n,n}) = \{v_0v_i, v_{2n+i} \mid 1 \leq i \leq n\} \). Then \( V(M(S_{1,n,n})) = V(S_{1,n,n}) \cup \mathcal{M} \), where \( \mathcal{M} = \{m_i \mid 1 \leq i \leq n\} \).

If \( S = \mathcal{M} \), then \( S \) is a total dominating set of \( M(S_{1,n,n}) \) with \( |S| = 2n \), and hence \( \gamma_t(M(S_{1,n,n})) \leq 2n \).

On the other hand, let \( S \) be a total dominating set \( M(S_{1,n,n}) \). By Lemma 2.1, we can assume that \( S \subseteq \mathcal{M} \). Since, for every \( 1 \leq i \leq n \), \( N_{M(S_{1,n,n})}(v_{n+i}) = \{m_{i(n+i)}\} \), then \( m_{i(n+i)} \in S \) for every \( 1 \leq i \leq n \). Similarly, for every \( 1 \leq i \leq n \), \( N_{M(S_{1,n,n})}(m_{i(n+i)}) = \{m_i, v_i, v_{n+i}\} \) implies that \( m_i \in S \) for every \( 1 \leq i \leq n \), and hence \( \mathcal{M} \subseteq S \). This implies \( \gamma_t(M(S_{1,n,n})) \geq 2n \). \( \square \)

**Proposition 2.6.** For any path \( P_n \) of order \( n \geq 3 \),

\[
\gamma_t(M(P_n)) = \left\lceil \frac{2n}{3} \right\rceil.
\]

**Proof.** To fix the notation, assume \( V(P_n) = \{v_1, \ldots, v_n\} \) and \( E(P_n) = \{v_iv_{i+1} \mid 1 \leq i \leq n-1\} \). Then \( V(M(P_n)) = V \cup \mathcal{M} \) where \( V = V(P_n) \) and \( \mathcal{M} = \{m_{i(i+1)} \mid 1 \leq i \leq n-1\} \).

If \( n \equiv 0 \mod 3 \), then consider

\[
S = \{m_{12}, m_{23}, m_{45}, m_{56}, \ldots, m_{(n-2)(n-1)}, m_{(n-1)n}\}.
\]

We have that \( S \) is a total dominating set of \( M(P_n) \) with \( |S| = \frac{2n}{3} \). If \( n \equiv 1 \mod 3 \), then consider

\[
S = \{m_{12}, m_{23}, m_{45}, m_{56}, \ldots, m_{(n-3)(n-2)}, m_{(n-2)(n-1)}\} \cup \{m_{(n-1)n}\}.
\]

We have that \( S \) is a total dominating set of \( M(P_n) \) with \( |S| = \left\lceil \frac{2n}{3} \right\rceil \). If \( n \equiv 2 \mod 3 \), then consider

\[
S = \{m_{12}, m_{23}, m_{45}, m_{56}, \ldots, m_{(n-4)(n-3)}, m_{(n-3)(n-2)}\} \cup \{m_{(n-2)(n-1)}, m_{(n-1)n}\}.
\]

We have that \( S \) is a total dominating set of \( M(P_n) \) with \( |S| = \left\lceil \frac{2n}{3} \right\rceil \).

This implies \( \gamma_t(M(P_n)) \leq \left\lceil \frac{2n}{3} \right\rceil \).

On the other hand, let \( S \) be a total dominating set for \( M(P_n) \). For every \( i = 1, \ldots, n - 2 \), let \( G_i = P_n[v_i, v_{i+1}, v_{i+2}] \). Since \( S \) dominates all
vertices of the graph $M(G_i)$, $|S \cap V(G_i)| \geq 2$. This implies that $|S| \geq \lceil \frac{2n}{3} \rceil$. \hfill \qed

Since if we delete a vertex from a complete graph $K_{n+1}$ we obtain a graph isomorphic to $K_n$, Lemma 2.2 gives us the following result.

**Lemma 2.7.** For any $n \geq 3$, we have

$$\gamma_t(M(K_n)) \leq \gamma_t(M(K_{n+1})) \leq \gamma_t(M(K_n)) + 1.$$  

**Proposition 2.8.** Let $K_n$ be the complete graph on $n \geq 2$ vertices. Then

$$\gamma_t(M(K_n)) = \left\lceil \frac{2n}{3} \right\rceil$$

\textit{Proof.} If $2 \leq n \leq 4$, a direct computation shows that $\gamma_t(M(K_n)) = \left\lceil \frac{2n}{3} \right\rceil$. Assume now $n \geq 5$. The graph $K_n$ has several subgraphs isomorphic to $P_n$, and hence $M(K_n)$ has subgraphs isomorphic to $M(P_n)$. Fix one of those and consider $S$ a total dominating set for $M(P_n)$. Since $S$ is also a total dominating set for $M(K_n)$, we have $\gamma_t(M(K_n)) \leq \left\lceil \frac{2n}{3} \right\rceil$.

We will prove the opposite inequality by induction. Assume that we have equality for $\gamma_t(M(K_n))$ and we want to prove it for $\gamma_t(M(K_{n+1}))$. If $n \equiv 2 \mod 3$, then $n + 1 \equiv 0 \mod 3$, and hence, $\gamma_t(M(K_n)) = \left\lceil \frac{2n}{3} \right\rceil = \left\lceil \frac{2(n+1)}{3} \right\rceil$. On the other hand, by Lemma 2.7, $\gamma_t(M(K_n)) \leq \gamma_t(M(K_{n+1}))$. This fact, together with the first part of the proof, implies that $\gamma_t(M(K_{n+1})) = \left\lceil \frac{2(n+1)}{3} \right\rceil$. If $n \equiv 0, 1 \mod 3$, by Lemma 2.7 and the first part of the proof, it is enough to show that $\gamma_t(M(K_n)) < \gamma_t(M(K_{n+1}))$. As a contradiction, assume that $\gamma_t(M(K_n)) = \gamma_t(M(K_{n+1}))$. If $n \equiv 0 \mod 3$, then $n - 1 \equiv 2 \mod 3$, and hence this would imply $\gamma_t(M(K_{n-1})) = \gamma_t(M(K_n)) = \gamma_t(M(K_{n+1}))$. Similarly, if $n \equiv 1 \mod 3$, then $n + 1 \equiv 2 \mod 3$, and hence $\gamma_t(M(K_n)) = \gamma_t(M(K_{n+1})) = \gamma_t(M(K_{n+2}))$. Hence we need to show that $\gamma_t(M(K_n)) < \gamma_t(M(K_{n+2}))$, when $n \geq 4$. Let $S$ be a total dominating set of $M(K_{n+2})$. To fix the notation, assume $V(K_{n+2}) = \{v_1, \ldots, v_{n+2}\}$ and $V(M(K_{n+2})) = V(K_{n+2}) \cup \mathcal{M}$, where $\mathcal{M} = \{m_{ij} \mid 1 \leq i < j \leq n + 2\}$. By Lemma 2.1, we can assume that $S \subseteq \mathcal{M}$. After possibly relabeling $V(K_{n+2})$, we can assume that $m_{(n+1)(n+2)} \in S$. Since $S$ is a total dominating set of $M(K_{n+2})$, then it contains at least one element of the form $m_{i(n+1)}$ or $m_{i(n+2)}$, for some $i = 1, \ldots, n$. By construction, $M(K_n)$ is isomorphic to $M(K_{n+2}[v_1, \ldots, v_n])$, this implies that, similarly to the proof of Lemma 2.7, we can construct $S'$ a total dominating set of $M(K_n)$ by exchanging a vertex of the form $m_{i(n+1)}$ or $m_{i(n+2)}$ with one of the form $m_{ij}$ and just discarding $m_{(n+1)(n+2)}$. This implies that $|S'| < |S|$, and hence $\gamma_t(M(K_n)) < \gamma_t(M(K_{n+2}))$. \hfill \qed

**Theorem 2.9.** Let $G$ be any graph of order $n$. Then

$$\left\lceil \frac{2n}{3} \right\rceil \leq \gamma_t(M(G)) \leq n - 1$$
Proof. From $G$ we can obtain graph isomorphic to $K_n$ by adding all the necessary edges. This implies that we can see $G$ as a subgraph of $K_n$, and hence $M(G)$ as a subgraph of $M(K_n)$. Since any total dominating set of $M(G)$ is also a total dominating set for $M(K_n)$, this implies that $\gamma_t(M(G)) \geq \gamma_t(M(K_n))$. We obtain the left inequality by Proposition 2.8.

Let $T$ be a spanning tree of $G$ and $S$ a minimal total dominating set of $M(T)$. By Lemma 2.1, we can assume that $S \subseteq E(T)$. This implies that $|S| \leq |E(T)| = n - 1$. By construction, $S$ is also a total dominating set of $M(G)$, and hence $\gamma_t(M(G)) \leq n - 1$. □

**Remark 2.10.** By Propositions 2.3 and 2.6, the inequalities of Theorem 2.9 are all sharp.

**Theorem 2.11.** If $G$ is a graph with order $n$ and there exists a subgraph of $G$ isomorphic to $P_n$, then

$$\gamma_t(M(G)) = \left\lceil \frac{2n}{3} \right\rceil.$$ 

**Proof.** Since $G$ has a subgraph isomorphic to $P_n$, then $M(G)$ has a subgraph isomorphic to $M(P_n)$. Moreover, any total dominating set of $M(P_n)$ is also a total dominating set for $M(G)$. By Proposition 2.6, this implies that $\gamma_t(M(K_n)) \leq \left\lceil \frac{2n}{3} \right\rceil$. We conclude by Theorem 2.9. □

Directly from Theorem 2.11, we obtain the following result.

**Corollary 2.12.** For any $n \geq 3$,

$$\gamma_t(M(P_n)) = \gamma_t(M(C_n)) = \gamma_t(M(W_n)) = \gamma_t(M(K_n)) = \left\lceil \frac{2n}{3} \right\rceil.$$ 

**Definition 2.13.** The friendship graph $F_n$ of order $2n + 1$ is obtained by joining $n$ copies of the cycle graph $C_3$ with a common vertex.

**Proposition 2.14.** Let $F_n$ be the friendship graph with $n \geq 2$. Then

$$\gamma_t(M(F_n)) = 2n.$$ 

**Proof.** To fix the notation, assume $V(F_n) = \{v_0, v_1, \ldots, v_{2n}\}$ and $E(F_n) = \{v_0v_1, v_0v_2, \ldots, v_0v_{2n}\} \cup \{v_1v_2, v_3v_4, \ldots, v_{2n-1}v_{2n}\}$. Then $V(M(F_n)) = V(F_n) \cup \mathcal{M}$, where $\mathcal{M} = \{m_i \mid 1 \leq i \leq 2n\} \cup \{m_{i+1} \mid 1 \leq i \leq 2n - 1 \text{ and } i \text{ is odd}\}$.

Consider $S = \{m_{i+1} \mid 1 \leq i \leq 2n - 1 \text{ and } i \text{ is odd}\} \cup \{v_i \mid i \text{ is odd}\}$. Then $S$ is a total dominating set for $M(F_n)$ with $|S| = 2n$, and hence, $\gamma_t(M(F_n)) \leq 2n$.

On the other hand, since $F_n$ is obtained by joining $n$ copies of $C_3$ at $v_0$, any total dominating set $S$ of $M(F_n)$ induces a total dominating set of $M(C_3)$ as subgraph of $M(F_n)$. By Corollary 2.12, $\gamma_t(M(C_3)) = 2$. This fact together with the fact that any two distinct copies of $M(C_3)$ in $M(F_n)$ share only $v_0$ implies that $|S| \geq 2n$. This implies that $\gamma_t(M(F_n)) \geq 2n$. □
Using Theorem 2.9, we can describe the total domination number of the middle graph of a complete bipartite graph.

**Proposition 2.15.** Let $K_{n_1,n_2}$ be the complete bipartite graph with $n_2 \geq n_1 \geq 2$. Then

$$\gamma_t(M(K_{n_1,n_2})) = \begin{cases} n_2 + \lceil \frac{2n_1-n_2}{3} \rceil & \text{if } n_1 \leq n_2 \leq 2n_1 - 1 \\ n_2 & \text{if } n_2 \geq 2n_1. \end{cases}$$

**Proof.** Assume $V(K_{n_1,n_2}) = \{v_1, \ldots, v_{n_1}, u_1, \ldots, u_{n_2}\}$ and $E(K_{n_1,n_2}) = \{v_iu_j \mid 1 \leq i \leq n_1, 1 \leq j \leq n_2\}$. Then we have $V(M(K_{n_1,n_2})) = V(K_{n_1,n_2}) \cup M$, where $M = \{m_{ij} \mid 1 \leq i \leq n_1, 1 \leq j \leq n_2\}$.

Assume first $n_1 = n_2$. If $n_1 \equiv 0 \mod 3$, then consider

$$S = \{m_{11}, m_{12}, m_{23}, m_{33}, \ldots, m_{(n_1-1)n_1}, m_{n_1n_1}\}.$$ 

By construction, $S$ is a total dominating set of $M(K_{n_1,n_2})$ and $|S| = n_1 + \frac{n_1}{3} = n_2 + \frac{n_2}{3} = n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$. If $n_1 \equiv 1 \mod 3$, then consider

$$S = \{m_{11}, m_{12}, m_{23}, m_{33}, \ldots, m_{(n_1-1)(n_1-1)}, m_{(n_1-1)(n_1-1)}\} \cup \{m_{n_1n_1}\}.$$ 

By construction, $S$ is a total dominating set of $M(K_{n_1,n_2})$ and $|S| = n_1 + \lceil \frac{n_1}{3} \rceil = n_2 + \lceil \frac{n_2}{3} \rceil = n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$. If $n_1 \equiv 2 \mod 3$, then consider

$$S = \{m_{11}, m_{12}, m_{23}, m_{33}, \ldots, m_{(n_1-1)n_1}, m_{n_1n_1}\} \cup \{m_{n_1n_1}\}.$$ 

By construction, $S$ is a total dominating set of $M(K_{n_1,n_2})$ and $|S| = n_1 + \left\lceil \frac{n_1}{3} \right\rceil = n_2 + \left\lceil \frac{n_2}{3} \right\rceil = n_2 + \left\lceil \frac{2n_1-n_2}{3} \right\rceil$.

Assume that $n_1 + 1 \leq n_2 \leq 2n_1 - 1$. Consider

$$S' = \{m_{11}, m_{1n_1+1}, \ldots, m_{(n_2-n_1+1)n_1}, m_{n_2-n_1+n_1}\}.$$ 

Let $G = K_{n_1,n_2}[u_{n_2-n_1+1}, u_{n_2-n_1+1}, \ldots, v_{n_1}]$. Then $G$ is isomorphic to a graph of the form $K_{n,n}$, where $n = 2n_1 - n_2$. This implies that by the first part of the proof, we can construct $S''$ a total dominating set of $M(G)$ with $|S''| = 2n_1 - n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$. Consider $S = S' \cup S''$. Then $S$ is a total dominating set of $M(K_{n_1,n_2})$ and $|S| = 2(n_2-n_1) + 2n_1 - n_2 + \lceil \frac{2n_1-n_2}{3} \rceil = n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$.

This implies that if $n_1 \leq n_2 \leq 2n_1 - 1$, then $\gamma_t(M(K_{n_1,n_2})) \leq n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$.

Assume now that $n_2 \geq 2n_1$. Consider

$$S = \{m_{11}, m_{1n_1+1}, \ldots, m_{n_1n_1}, m_{n_2n_2}\} \cup \{m_{n_12n_1+1}, \ldots, m_{n_1n_2}\},$$

then $S$ is a total dominating set of $M(K_{n_1,n_2})$ with $|S| = n_2$, and hence, $\gamma_t(M(K_{n_1,n_2})) \leq n_2$.

On the other hand, assume first $n_1 = n_2$. By Theorem 2.9, we have $\gamma_t(M(K_{n_1,n_2})) \geq \lceil \frac{2(n_1+n_2)}{3} \rceil = n_2 + \lceil \frac{2n_1-n_2}{3} \rceil$.

Assume that $n_1 + 1 \leq n_2 \leq 2n_1 - 1$. Let $S$ be a total dominating set of $M(K_{n_1,n_2})$. By Lemma 2.1, we can assume that $S \subseteq M$. The construction of the first part of the proof is optimal since $S'$ and $S''$ have the smallest possible size by the argument discussed when $n_1 = n_2$ and $n_2 \geq 2n_1$. 

TOTAL DOMINATION NUMBER OF MIDDLE GRAPHS 7
This implies that if \( n_1 \leq n_2 \leq 2n_1 - 1 \), then \( \gamma_t(M(K_{n_1,n_2})) = n_2 + \left\lceil \frac{2n_1-n_2}{3} \right\rceil \).

Assume that \( n_2 \geq 2n_1 \), then by [9, Proposition 3.13], we have \( n_2 = \gamma(M(K_{n_1,n_2})) \leq \gamma_t(M(K_{n_1,n_2})) \leq n_2 \). This implies that \( \gamma_t(M(K_{n_1,n_2})) = n_2 \).

\[ \square \]

3. The middle graph of a tree

Similarly to [9, Proposition 2.4], if we consider \( T \) a tree and we denote by \( \text{leaf}(T) = \{ v \in V(T) \mid d_T(v) = 1 \} \) the set of leaves of \( T \), then we have the following result.

**Proposition 3.1.** Let \( T \) be a tree with \( n \geq 2 \) vertices. Then
\[
\gamma_t(M(T)) \geq |\text{leaf}(T)|.
\]

**Proof.** To fix the notation, assume \( \text{leaf}(T) = \{ v_1, \ldots, v_k \} \), for some \( k \leq n \). If \( n = 2 \), then \( T \) is isomorphic to \( P_2 \) and hence \( \gamma_t(M(T)) = 2 = |\text{leaf}(T)| \). Assume that \( n \geq 3 \) and let \( S \) be a total dominating set of \( M(T) \). Then, for each \( i = 1, \ldots, k \), \( S \cap N_{M(T)}[v_i] \neq \emptyset \). Since, if \( i \neq j \), then \( N_{M(T)}[v_i] \cap N_{M(T)}[v_j] = \emptyset \), we have that \( |S| \geq k \). This implies that \( \gamma_t(M(T)) \geq k = |\text{leaf}(T)| \).

\[ \square \]

**Remark 3.2.** Notice that by Proposition 2.3, the inequality described in Proposition 3.1 is sharp.

It is sufficient to add some assumptions on the diameter of a tree \( T \), to compute \( \gamma_t(M(T)) \) explicitly.

**Theorem 3.3.** Let \( T \) be a tree of order \( n \geq 4 \) with \( \text{diam}(T) = 3 \). Then
\[
\gamma_t(M(T)) = \begin{cases} 
  n - 2 & \text{if there are two vertices with } d_T(v) \geq 3 \\
  n - 1 & \text{otherwise}.
\end{cases}
\]

**Proof.** Since by assumption \( \text{diam}(T) = 3 \), then \( T \) is a tree which is obtained by joining central vertex \( v \) of \( K_{1,p} \) and the central vertex \( w \) of \( K_{q,1} \) where \( p+q = n-2 \). Let \( \text{leaf}(T) = \{ v_i \mid 1 \leq i \leq n-2 \} \) be the set of leaves of \( T \). Obviously \( V(T) = \text{leaf}(T) \cup \{ v, w \} \) and \( |\text{leaf}(T)| = n - 2 \). Define \( v_{n-1} = v \) and \( v_n = w \).

Assume first that \( p, q \geq 2 \), i.e. there are two vertices with \( d_T(u) \geq 3 \). If we consider \( S = \{ m_{i(n-1)} \mid 1 \leq i \leq p \} \cup \{ m_{in} \mid p + 1 \leq i \leq n-2 \} \), then \( S \) is a total dominating set of \( M(T) \) with \( |S| = n - 2 \), and hence \( \gamma_t(M(T)) \leq n - 2 \). On the other hand, by Proposition 3.1, we have \( \gamma_t(M(T)) \geq n - 2 \).

Assume that \( p \geq 2 \) and \( q = 1 \), i.e. there is only one vertex with \( d_T(u) \geq 3 \). Let \( S \) be a total dominating set of \( M(T) \). By Lemma 2.1, we can assume that \( S \subseteq E(T) \). Since \( N_{M(T)}(v_i) = \{ m_{i(n-1)} \} \) for all \( 1 \leq i \leq p = n - 3 \) and \( N_{M(T)}(v_{n-2}) = \{ m_{(n-2)n} \} \), then \( \{ m_{i(n-1)} \mid 1 \leq i \leq p \} \cup \{ m_{(n-2)n} \} \).
$p \} \cup \{m_{(n-2)n}\} \subseteq S$. Moreover, $N_{M(T)}(m_{(n-2)n}) = \{m_{(n-1)n}, v_n, v_{n-2}\}$ implies that $m_{(n-1)n} \in S$. This implies that $|S| \geq n - 1$, and hence $\gamma_t(M(T)) \geq n - 1$. On the other hand, by Theorem 2.9, $\gamma_t(M(T)) \leq n - 1$.

Assume that $p, q = 1$, i.e. there are no vertices with $d_T(u) \geq 3$. This implies that $T$ is isomorphic to $P_4$ and $n = 4$, and hence by Proposition 2.6, $\gamma_t(M(T)) = 3 = n - 1$. \hfill \Box

In general, the opposite implication of Theorem 3.3 does not hold as the next example shows.

**Example 3.4.** Let $T$ be the tree in Figure 2. Then a direct computation shows that $\text{diam}(T) = 4$ and $\gamma_t(M(T)) = 5 = n - 2$.

![Figure 2. A tree on 7 vertices](image.png)

**Proposition 3.5.** Let $T$ be a tree of order $n \geq 3$ with $\text{diam}(T) = 2$. Then

$$\gamma_t(M(T)) = n - 1.$$  

**Proof.** Since by assumption $\text{diam}(T) = 2$, then $T$ is isomorphic to $K_{1,n-1}$. This implies, by Proposition 2.3, that $\gamma_t(M(T)) = n - 1$. \hfill \Box

**Remark 3.6.** By the proof of Theorem 3.3, differently from the case of domination (see [9, Theorem 3.2]), $\gamma_t(M(G)) = n - 1$ does not implies that $G$ is isomorphic to $K_{1,n-1}$.

4. Operations on graphs

In this section, similarly to [9], we study the total domination number of the middle graph of the corona, 2-corona and join with $K_p$ of a graph.

**Definition 4.1.** The corona $G \circ K_1$ of a graph $G$ is the graph of order $2|V(G)|$ obtained from $G$ by adding a pendant edge to each vertex of $G$.

**Example 4.2.** Consider the graph $P_3$, then the graph $P_3 \circ K_1$ is the one in Figure 3.

![Figure 3. The graph $P_3 \circ K_1$](image.png)
Theorem 4.3. For any connected graph $G$ of order $n \geq 2$,
\[ \gamma_t(M(G \circ K_1)) = n + \gamma(M(G)). \]

Proof. To fix the notation, assume $V(G) = \{v_1, \ldots, v_n\}$. Then $V(G \circ K_1) = \{v_1, \ldots, v_{2n}\}$ and $E(G \circ K_1) = \{v_1v_{n+1}, \ldots, v_nv_{2n}\} \cup E(G)$. Then $V(M(G \circ K_1)) = V(G \circ K_1) \cup \mathcal{M}$, where $\mathcal{M} = \{m_{(i+1)} | 1 \leq i \leq n\} \cup \{m_{ij} | v_iv_j \in E(G)\}$.

Let $S'$ be a minimal dominating set of $M(G)$. By construction, if we consider $S = S' \cup \{m_{(i+1)} | 1 \leq i \leq n\}$, then $S$ is a total dominating set of $M(G \circ K_1)$ with $|S| = n + \gamma(M(G))$, and hence $\gamma_t(M(G \circ K_1)) \leq n + \gamma(M(G))$.

On the other hand, let $S$ be a total dominating set of $M(G \circ K_1)$. By Lemma 2.1, we can assume that $S \subseteq \mathcal{M}$. Since $N_{M(G \circ K_1)}(v_{n+1}) = \{m_{(i+1)}\}$, for all $1 \leq i \leq n$, then $m_{(i+1)} \in S$, for all $1 \leq i \leq n$. In addition, $N_{M(G \circ K_1)}(m_{(i+1)}) = \{v_i, v_{i+1}\} \cup N_M(G)(v_i)$, for all $1 \leq i \leq n$, then $N_M(G)(v_i) \cap S \neq \emptyset$, for all $1 \leq i \leq n$. This implies that $S \cap E(G)$ is a dominating set of $M(G)$ and hence $|S| \geq n + \gamma(M(G))$. This implies that $\gamma_t(M(G \circ K_1)) \geq n + \gamma(M(G))$.

\[ \square \]

Definition 4.4. The 2-corona $G \circ P_2$ of a graph $G$ is the graph of order $3|V(G)|$ obtained from $G$ by attaching a path of length 2 to each vertex of $G$ so that the resulting paths are vertex-disjoint.

Example 4.5. Consider the graph $P_3$, then the graph $P_3 \circ P_2$ is the one in Figure 4.

![Figure 4. The graph $P_3 \circ P_2$](image)

Theorem 4.6. For any connected graph $G$ of order $n \geq 2$,
\[ \gamma_t(M(G \circ P_2)) = 2n. \]

Proof. To fix the notation, assume $V(G) = \{v_1, \ldots, v_n\}$. Then $V(G \circ P_2) = \{v_1, \ldots, v_{3n}\}$ and $E(G \circ P_2) = \{v_iv_{n+i}, v_{n+i}v_{2n+i} | 1 \leq i \leq n\} \cup E(G)$. Then $V(M(G \circ P_2)) = V(G \circ P_2) \cup \mathcal{M}$, where $\mathcal{M} = \{m_{(i+1)}, m_{(n+i)(2n+i)} | 1 \leq i \leq n\} \cup \{m_{ij} | v_iv_j \in E(G)\}$.

Let $S$ be a total dominating set of $M(G \circ P_2)$. By Lemma 2.1, we can assume that $S \subseteq \mathcal{M}$. Since $N_{M(G \circ P_2)}(v_{2n+i}) = \{m_{(n+i)(2n+i)}\}$, for every $1 \leq i \leq n$, we have $m_{(n+i)(2n+i)} \in S$ for every $1 \leq i \leq n$. In addition, $N_{M(G \circ P_2)}(m_{(n+i)(2n+i)}) = \{m_{(i+1)}, v_{2n+i}, v_{n+i}\}$, for every $1 \leq i \leq n$, implies that $m_{(i+1)} \in S$, for every $1 \leq i \leq n$. This implies that $|S| \geq 2n$, and hence $\gamma_t(M(G \circ P_2)) \geq 2n$. 

On the other hand, if we consider $S = \{m_i(n+i), m_i(n+i)(2n+i) \mid 1 \leq i \leq n\}$, then $S$ is a total dominating set of $M(G \circ P_2)$ with $|S| = 2n$, and hence $\gamma_t(M(G \circ P_2)) \leq 2n$.

**Definition 4.7.** The join $G + H$ of two graphs $G$ and $H$ is the graph with vertex set $V(G + H) = V(G) \cup V(H)$ and edge set $E(G + H) = E(G) \cup E(H) \cup \{vw \mid v \in V(G), w \in V(H)\}$.

**Example 4.8.** Consider the graphs $G = K_3$ and $H = P_2$, then graph $G + H$ is the one in Figure 5.

![Figure 5. The graph $K_3 + P_2$](image)

**Theorem 4.9.** For any connected graph $G$ of order $n \geq 2$,

$$\gamma_t(M(G + K_p)) = \begin{cases} p & \text{if } p \geq 2n \\ \left\lceil \frac{2(n+p)}{3} \right\rceil & \text{if } \frac{2}{3} \leq p \leq 2n - 1. \end{cases}$$

**Proof.** To fix the notation, assume $V(G) = \{v_1, \ldots, v_n\}$ and $V(K_p) = \{v_{n+1}, \ldots, v_{n+p}\}$. Then $V(M(G + K_p)) = V(G + K_p) \cup M_1 \cup M_2$ where $M_1 = \{m_{ij} \mid v_iv_j \in E(G)\}$ and $M_2 = \{m_i(n+j) \mid 1 \leq i \leq n, 1 \leq j \leq p\}$.

**Case $p \geq 2n$.** Let $S$ be a total dominating set of $M(G + K_p)$. By Lemma 2.1, we can assume $S \subseteq M_1 \cup M_2$. Since, if $j \neq k$, $N_{M(G + K_p)}(v_{n+j}) \cap N_{M(G + K_p)}(v_{n+k}) = \emptyset$, then for every $1 \leq j \leq p$ there exists $1 \leq i \leq n$ such that $m_i(n+j) \in S$, and hence $|S| \geq p$. This implies that $\gamma_t(M(G + K_p)) \geq p$. On the other hand, if we consider $S = \{m_i(n+i), m_i(2n+i) \mid 1 \leq i \leq n\} \cup \{m_i(3n+i) \mid 1 \leq i \leq p - 2n\}$, then $S$ is a total dominating set of $M(G + K_p)$ with $|S| = p$, and hence $\gamma_t(M(G + K_p)) \leq p$.

**Case $p = 2n - 1$.** If we consider $S = \{m_i(n+i), m_i(2n+i) \mid 1 \leq i \leq n - 1\} \cup \{m_n(2n), m_n(2n-1)\}$, then $S$ is a total dominating set of $M(G + K_{2n-1})$ with $|S| = 2n$, and hence $\gamma_t(M(G + K_{2n-1})) \leq 2n$. On the other hand, by Theorem 2.9, $\gamma_t(M(G + K_{2n-1})) \geq \left\lceil \frac{2(3n-1)}{3} \right\rceil = 2n$, and hence $\gamma_t(M(G + K_{2n-1})) = 2n = \left\lceil \frac{2(n+p)}{3} \right\rceil$.

**Case $n + 3 \leq p \leq 2n - 2$.** Assume that $p = n + k$ with $3 \leq k \leq n - 2$. The graph $G + K_p$ has $k$ subgraphs isomorphic to $P_3$ and one subgraph isomorphic to $P_{2(n-k)}$ that are all disjoint. In fact, the $k$ subgraphs $(G + K_p)[v_1, v_{n+1}, v_{2n+1}], \ldots, (G + K_p)[v_k, v_{n+k}, v_{2n+k}]$ are all isomorphic to $P_3$ and the subgraph $(G + K_p)[v_{k+1}, \ldots, v_n, v_{n+k+1}, \ldots, v_{2n}]$ has a subgraph isomorphic to $P_{2(n-k)}$. By Proposition 2.6, this implies that $\gamma_t(M(G + K_p)) \leq 2k + \left\lceil \frac{2(2(n-k))}{3} \right\rceil = \left\lceil \frac{2(n+p)}{3} \right\rceil$. By Theorem 2.9, we obtain the desired equality.
Case $p = n + 2$. If $n \equiv 0 \mod 3$, consider

$$S = \{m_1(n+1), m_1(n+2), m_2(n+3), m_3(n+3), \ldots, m_{(n-1)/2}(2n), m_n(2n), m_n(2n+1), m_n(2n+2)\}.$$  

Then $S$ is a total dominating set of $M(G + K_p)$ with $|S| = \lfloor \frac{2(n+p)}{3} \rfloor$. If $n \equiv 1 \mod 3$, consider

$$S = \{m_1(n+1), m_1(n+2), m_2(n+3), m_3(n+3), \ldots, m_2(2n), m_n(2n+1), m_n(2n+2)\}.$$  

Then $S$ is a total dominating set of $M(G + K_p)$ with $|S| = \lfloor \frac{2(n+p)}{3} \rfloor$. If $n \equiv 2 \mod 3$, consider

$$S = \{m_1(n+1), m_1(n+2), m_2(n+3), m_3(n+3), \ldots, m_{n(2n+1)}, m_n(2n+2)\}.$$  

Then $S$ is a total dominating set of $M(G + K_p)$ with $|S| = \lfloor \frac{2(n+p)}{3} \rfloor$. This implies that $\gamma_t(M(G + K_p)) \leq \lfloor \frac{2(n+p)}{3} \rfloor$. By Theorem 2.9, we then obtain that $\gamma_t(M(G + K_p)) = \lfloor \frac{2(n+p)}{3} \rfloor$.

Case $n-1 \leq p \leq n + 1$. If $p = n-1$, then the graph $G + K_p$ contains the path $P : v_1v_1v_2v_2v_3 \cdots v_nvp$. If $p = n$, then $G + K_p$ contains the path $P' : v_1v_1v_2v_2v_3 \cdots v_{n-1}vp$. If $p = n+1$, then $G + K_p$ contains the path $P'' : v_1v_1v_2v_2v_3 \cdots v_{n-1}v_nv_{n+p}$.

By Theorem 2.11, and obtain that $\gamma_t(M(G + K_p)) = \lfloor \frac{2(n+p)}{3} \rfloor$.

Case $\frac{n}{2} \leq p \leq n - 2$. Assume that $p = n - k$ with $2 \leq k \leq \frac{n}{2}$.

If $n$ is even and $p = \frac{n}{2}$ (or equivalently $k = \frac{n}{2}$), then the set $S = \{m_i(n+i), m_i+\frac{n}{2}(n+i) \mid 1 \leq i \leq \frac{n}{2}\}$ is a total dominating set of $M(G + K_p)$ with $|S| = n = \lfloor \frac{2(n+p)}{3} \rfloor$. This implies that $\gamma_t(M(G + K_p)) \leq \lfloor \frac{2(n+p)}{3} \rfloor$, and by Theorem 2.9, we obtain the desired equality.

Assume that $2 \leq k \leq \frac{n}{2} - 1$. The graph $G + K_p$ has $k$ subgraphs isomorphic to $P_3$ and one subgraph isomorphic to $P_{2(n-2k)}$ that are all disjoint. In fact, the $k$ induced subgraphs $(G + K_p)[v_1, v_{n+1}, v_{k+1}], \ldots, (G + K_p)[v_k, v_{n+k}, v_{2k}]$ are all isomorphic to $P_3$ and the induced subgraph $(G + K_p)[v_{2k+1}, \ldots, v_n, v_{n+k+1}, \ldots, v_{2n-k}]$ has a subgraph isomorphic to $P_{2(n-2k)}$. By Proposition 2.6, this implies that $\gamma_t(M(G + K_p)) \leq 2k + \lfloor \frac{2(n-2k)}{3} \rfloor = \lfloor \frac{2(n+p)}{3} \rfloor$. By Theorem 2.9, we obtain the desired equality.

Similarly to [9], when $p$ is small relatively to $n$, $\gamma_t(M(G + K_p))$ is strongly related to $\gamma_t(M(G))$.

**Theorem 4.10.** For any connected graph $G$ of order $n \geq 2$ and any integer $1 \leq p \leq \frac{n}{2} - 1$,

$$\left\lfloor \frac{2(n+p)}{3} \right\rfloor \leq \gamma_t(M(G + K_p)) \leq 2p + \min\{\gamma_t(M(G[A])) \mid A \subseteq V(G), |A| = n - 2p, G[A] has no isolated vertices\}.$$
Proof. To fix the notation, assume \( V(G) = \{v_1, \ldots, v_n\} \) and \( V(K_p) = \{v_{n+1}, \ldots, v_{n+p}\} \). Then \( V(M(G + K_p)) = V(G + K_p) \cup M_1 \cup M_2 \) where \( M_1 = \{m_{ij} \mid v_iv_j \in E(G)\} \) and \( M_2 = \{m_{i(n+j)} \mid 1 \leq i \leq n, 1 \leq j \leq p\} \).

By Theorem 2.9, we obtain the first inequality. Let now \( A \subseteq V(G) \) be such that \( |A| = n - 2p \) and \( G[A] \) has no isolated vertices. Without loss of generality, we can assume that \( A = \{v_{2p+1}, \ldots, v_n\} \). Consider \( S' \) be a minimal total dominating set of \( M(G[A]) \), then \( S = S' \cup \{m_{i(n+i)}, m_{(p+i)(n+i)} | 1 \leq i \leq p\} \) is a total dominating set of \( M(G + K_p) \).

Since this arguments works for every \( A \subseteq V(G) \) such that \( |A| = n - 2p \) and \( G[A] \) has no isolated vertices, we obtain the second inequality.

\[\square\]

If we apply Lemma 2.2 to the graph \( G + K_1 \), we obtain the following result.

**Lemma 4.11.** Let \( G \) be a graph of order \( n \geq 2 \) with no isolated vertices. Then

\[
\gamma_t(M(G)) \leq \gamma_t(M(G + K_1)) \leq \gamma_t(M(G)) + 1.
\]

Notice that both inequalities described in Lemma 4.11 are sharp as the following examples show.

**Example 4.12.** Consider the graph \( G = C_5 \). Then \( G + K_1 \) is isomorphic to \( W_6 \). This implies that by Corollary 2.12, \( \gamma_t(M(G)) = 4 = \gamma_t(M(G + K_1)) \).

![Figure 6. The graph \( P_3 + K_1 \)](image)

**Example 4.13.** Consider the graph \( G = P_3 \). Then \( G + K_1 \) is the graph in Figure 6. By Proposition 2.6 and Theorem 2.11, we have that \( \gamma_t(M(P_3)) = 2 \) and \( \gamma_t(M(P_3 + K_1)) = 3 \).

**Proposition 4.14.** For any star graph \( K_{1,n} \) on \( n + 1 \) vertices, with \( n \geq 4 \), we have

\[
\gamma_t(M(K_{1,n} + K_1)) = n.
\]

**Proof.** To fix the notation, assume \( V(K_{1,n}) = \{v_0, v_1, \ldots, v_n\} \), \( V(K_1) = \{v_{n+1}\} \) and \( E(K_{1,n}) = \{v_0v_1, v_0v_2, \ldots, v_0v_n\} \). Then \( V(M(K_{1,n} + K_1)) = V(K_{1,n}) \cup M \), where \( M = \{m_i \mid 1 \leq i \leq n\} \cup \{m_{i(n+i)} | 0 \leq i \leq n\} \).

By Proposition 2.3 and Lemma 4.11, \( \gamma_t(M(K_{1,n} + K_1)) \geq n \). On the other hand, consider \( S = \{m_i \mid 1 \leq i \leq n - 2\} \cup \{m_{(n-1)(n+1)}, m_{n(n+1)}\} \) is a total dominating set of \( M(K_{1,n} + K_1) \) with \( |S| = n \), and hence \( \gamma_t(M(K_{1,n} + K_1)) \leq n \).

\[\square\]
Remark 4.15. Proposition 4.14 shows that the upper bound of Theorem 4.10 is sharp. In fact, if $A \subseteq V(K_{1,n})$ with $|A| = n - 2$ and $G[A]$ has no isolated vertices, then $G[A]$ is isomorphic to $K_{1,n-2}$, and hence by Proposition 2.3, $\gamma_t(M(G[A])) = n - 2$.

Proposition 4.16. Let $G$ be a graph of order $n \geq 2$ and $1 \leq p \leq \frac{n}{2} - 1$. If $G$ has a subgraph isomorphic to a path graph $P_n$, then

$$\gamma_t(M(G + \overline{K_p})) = \left\lceil \frac{2(n + p)}{3} \right\rceil.$$

Proof. Under our assumption, the graph $G + \overline{K_p}$ contains a subgraph isomorphic to $P_{n+p}$. By Theorem 2.11, this implies that $\gamma_t(M(G + \overline{K_p})) = \left\lceil \frac{2(n+p)}{3} \right\rceil$. □

As a direct consequence of Proposition 4.16, we obtain the following result.

Corollary 4.17. Let $G$ be a graph of order $n \geq 2$ and $1 \leq p \leq \frac{n}{2} - 1$. If $G$ is isomorphic to a path graph $P_n$, or a cycle graph $C_n$, or a wheel graph $W_n$, or a complete graph $K_n$, then

$$\gamma_t(M(G + \overline{K_p})) = \left\lceil \frac{2(n + p)}{3} \right\rceil.$$

5. Nordhaus-Gaddum relations

In [11], Nordhaus and Gaddum gave a lower bound and an upper bound, in terms of the order of the graph, on the sum and the product of the chromatic number of a graph and its complement. Since then, lower and upper bounds on the sum and the product of many other graph invariants, like domination and total domination numbers, have been proposed by several authors. See [1] for a survey on the subject.

Theorem 5.1. Let $G$ be a graph on $n \geq 2$ vertices. Assume that the graphs $G$ and $\overline{G}$ have no isolated vertices and no components isomorphic to $K_2$. Then

$$2(n - 1) \geq \gamma_t(M(G)) + \gamma_t(M(\overline{G})) \geq 2\left\lceil \frac{2n}{3} \right\rceil$$

and

$$(n - 1)^2 \geq \gamma_t(M(G)) \cdot \gamma_t(M(\overline{G})) \geq \left(\left\lceil \frac{2n}{3} \right\rceil \right)^2.$$

Proof. By applying Theorem 2.9 to each component of $G$ and $\overline{G}$, we obtain that $n - 1 \geq \gamma_t(M(G)) \geq \left\lceil \frac{2n}{3} \right\rceil$ and $n - 1 \geq \gamma_t(M(\overline{G})) \geq \left\lceil \frac{2n}{3} \right\rceil$. □

Remark 5.2. If in Theorem 5.1 we allow $G$ or $\overline{G}$ to have components isomorphic to $K_2$, then the described upper bounds might not work. To see this it is enough to consider the graph $C_4$. In fact, $C_4$ consists of two copies of $K_2$, and then $\gamma_t(M(C_4)) = 3$ and $\gamma_t(M(\overline{C_4})) = 4$. 

Notice that all the inequalities of Theorem 5.1 are sharp, in fact we have the following example.

**Example 5.3.** Consider the graph $P_4$, then by Proposition 2.6, we have $\gamma_t(M(P_4)) = 3$. On the other hand, $\overrightarrow{P_4}$ is isomorphic to $P_4$, and hence $\gamma_t(M(\overrightarrow{P_4})) = 3$. Since $n = 4$, then $6 = \gamma_t(M(P_4)) + \gamma_t(M(\overrightarrow{P_4})) = 2(n - 1) = 2\left\lceil \frac{2n}{3} \right\rceil$, and $9 = \gamma_t(M(P_4)) \cdot \gamma_t(M(\overrightarrow{P_4})) = (n - 1)^2 = \left(\left\lceil \frac{2n}{3} \right\rceil \right)^2$.
