Abstract

Let $CT_n$ be the semigroup of full contraction mappings on $[n] = \{1, 2, \ldots, n\}$, and let $OCT_n$ and $ODCT_n$ be the subsemigroups consisting of all order-preserving full contraction and subsemigroup of order-decreasing and order-preserving full contraction mappings, respectively. In this paper, we show that the semigroup $ODCT_n$ is left adequate. We further study the rank properties and as well obtain the rank of the semigroup, $ODCT_n$. Moreover, we obtain a characterization of natural partial order for the semigroup $OCT_n$ and its subsemigroup $ODCT_n$, respectively.

2010 Mathematics Subject Classification. 20M20.

1 Introduction

Denote $[n]$ to be a finite chain $\{1, 2, \ldots, n\}$ and $P_n$ (resp., $T_n$) to be the semigroup of partial transformations on $[n]$ (resp., semigroup of full transformations on $[n]$). A map $\alpha \in T_n$ is said to be order-preserving (resp., order-reversing) if (for all $x, y \in [n]$) $x \leq y$ implies $x\alpha \leq y\alpha$ (resp., $x\alpha \geq y\alpha$); is order-increasing (resp., order-decreasing) if (for all $x \in [n]$) $x \leq x\alpha$ (resp., $x\alpha \leq x$); an isometry (i.e., distance preserving) if (for all $x, y \in [n]$) $|x\alpha - y\alpha| = |x - y|$ and a contraction if (for all $x, y \in [n]$) $|x\alpha - y\alpha| \leq |x - y|$. The collection of all contraction mappings on $[n]$ denoted by $CT_n$ is known to be the semigroup of full contraction mappings. The study of this semigroup and some of its subsemigroups was first proposed in 2013 by Umar and Alkharousi [30]. In this proposal, notations for the semigroup and some of its various subsemigroups were given. We will also maintain the same notations in this paper. Let

\[ OCT_n = \{ \alpha \in CT_n : (\text{for all } x, y \in [n]) \ x \leq y \Rightarrow x\alpha \leq y\alpha \} \]  

be the semigroup of order-preserving full contractions,

\[ ORCT_n = OCT_n \cup \{ \alpha \in CT_n : (\text{for all } x, y \in [n]) \ x \leq y \Rightarrow x\alpha \geq y\alpha \} \]  

*Corresponding Author. Email: mmzubairu.mth@buk.edu.ng
be the semigroup of order-preserving or order-reversing full contractions and
\[ \text{ODCT}_n = \{ \alpha \in \text{OCT}_n : (\text{for all } x \in [n]) \Rightarrow x\alpha \leq x \} \]  
be the semigroup of order-decreasing and order-preserving full contractions on \([n]\). Then it is clear that \(\text{ORCT}_n\) is a subsemigroup of \(\text{CT}_n\), while \(\text{ODCT}_n\) and \(\text{OCT}_n\) are subsemigroups of \(\text{ORCT}_n\). In 2013, Zhao and Yang [34] characterized regular elements and all the Green’s equivalences for the semigroup \(\text{OCP}_n\) (where \(\text{OCP}_n\) denote the semigroup of order-preserving partial contractions on \([n]\)). Ali et al. [31] extend the results of Zhao and Yang [34] to a more general semigroup of partial contractions \(\text{CP}_n\). They obtained a characterization for the regular elements and all the Green’s relations for the larger semigroup \(\text{CP}_n\). The complete characterization of Green’s relations for the semigroup of full contractions \(\text{CT}_n\) were all obtained in [31]. It is worth noting that the combinatorial results for the semigroups \(\text{ORCT}_n\), \(\text{OCT}_n\) and \(\text{ODCT}_n\) were investigated by Adeshola and Umar [1]. Moreover, Lem [31] obtained the rank of the two sided ideal of the semigroups \(\text{OCT}_n\) and \(\text{ORCT}_n\). However, it appears that the rank and algebraic properties of the semigroup \(\text{ODCT}_n\) have not been investigated. In this paper, we intend to study the Green’s relations, their starred analogue and rank properties. We also intend to characterize the semigroup \(\text{ODCT}_n\) when all but not right abundant for \(n \geq 3\). In section 4, we show that \(\text{ODCT}_n\) is left adequate and moreover, we investigate the rank of \(\text{ODCT}_n\). In section 5, we characterize partial order relation on \(\text{OCT}_n\) and \(\text{ODCT}_n\).

In this section, we give a brief introduction, basic definitions and characterize the elements of \(\text{ODCT}_n\). In section 2, we characterize all the Green’s equivalence and the regular elements in \(\text{ODCT}_n\). In section 3, we characterize the starred analogue of the Green’s equivalences and show that \(\text{ODCT}_n\) is left abundant for all \(n\) but not right abundant for \(n \geq 3\). In section 4, we show that \(\text{ODCT}_n\) is left adequate and moreover, we investigate the rank of \(\text{ODCT}_n\). In section 5, we characterize partial order relation on \(\text{OCT}_n\) and \(\text{ODCT}_n\).

For a contraction \(\alpha \in \text{CT}_n\), we shall denote \(\Im \alpha\), \(\text{rank } \alpha\) and \(\text{id}_A\) to be the image of \(\alpha\), \(|\Im \alpha|\) and identity on \(A \subseteq [n]\), respectively. For \(\alpha, \beta \in \text{CT}_n\), the composition of \(\alpha\) and \(\beta\) is defined as \(x(\alpha \circ \beta) = (x\alpha)\beta\) for all \(x \in [n]\). We shall be using the notation \(\alpha \beta\) to denote \(\alpha \circ \beta\) in our subsequent discussions. An element \(\alpha\) in a semigroup \(S\) is said to be an idempotent if and only if \(a^2 = a\). It is well known that \(\alpha \in \mathcal{T}_n\) is an idempotent if and only if \(\Im \alpha = F(\alpha)\) (where \(F(\alpha) = \{x \in [n] : x\alpha = x\}\)). If \(S\) is a commutative semigroup and all its elements are idempotents (i.e., \(S = E(S)\)), then \(S\) is said to be a semilattice. In this case, for all \(\alpha, \beta \in S\), \(\alpha^2 = \alpha\) and \(\alpha \beta = \beta \alpha\). For basic concepts in semigroup theory, we refer the reader to [14, 17].

Next, given any transformations \(\alpha \in \text{OCT}_n\), the domain of \(\alpha\) is partitioned into blocks by the relation \(\ker \alpha = \{(x, y) \in [n] \times [n] : x\alpha = y\alpha\}\), so that as in [34] \(\alpha\) can be expressed as

\[ \alpha = \left( \begin{array}{cccc} A_1 & A_2 & \cdots & A_p \\ x+1 & x+2 & \cdots & x+p \end{array} \right) (1 \leq p \leq n), \]

where \(A_i (1 \leq i \leq p)\) are equivalence classes under the relation \(\ker \alpha\), i.e., \(A_i = (x+i)\alpha^{-1}(1 \leq i \leq p)\) (with \(A_1 < A_2 < \cdots < A_p\)) and only if \(i < j\), moreover \((x+i) - (x+i-1) \leq \min A_i - \max A_{i-1}, i = 2, \ldots, p-1\) (if \(p > 1\)). We shall denote the partition of \([n]\) (by the relation \(\ker \alpha\)) by \(\text{Ker} \alpha = \{A_1, A_2, \ldots, A_p\}\) so that \([n] = \cup A_1 \cup A_2 \cup \cdots \cup A_p\) where \((1 \leq p \leq n)\).

A subset \(T_\alpha\) of \([n]\) is said to be a transversal of the partition \(\text{Ker} \alpha\) if \(|T_\alpha| = p\) and \(|A_i \cap T_\alpha| = 1\) (1 \(\leq i \leq p\)). A transversal \(T_\alpha\) of \(\text{Ker} \alpha\) is said to be convex if for all \(x, y \in T\alpha\) with \(x \leq y\) and if \(x < z < y\) for \(z \in [n]\) then \(z \in T\alpha\). A transversal \(T_\alpha\) is said to be admissible if and only if the map \(A_i \mapsto t_i\) \((t_i \in T\alpha, i \in \{1, 2, \ldots, p\})\) is a contraction. The partition \(\text{Ker} \alpha\) is said to be a convex partition if it has a convex admissible transversal.

The elements in \(\text{ODCT}_n\) can be uniquely expressed as in the following lemma:

**Lemma 1.** Every element \(\alpha \in \text{ODCT}_n\) can be expressed as

\[ \alpha = \left( \begin{array}{cccc} A_1 & A_2 & \cdots & A_p \\ 1 & 2 & \cdots & p \end{array} \right) (1 \leq p \leq n). \]
Proof. Let $\alpha \in ODCT_n$ be as expressed in equation (4), i.e.,

$$\alpha = \begin{pmatrix} A_1 & A_2 & \cdots & A_p \\ x+1 & x+2 & \cdots & x+p \end{pmatrix}$$

Since $\alpha$ is order-preserving then $A_1 < A_2 < \ldots < A_p$ and $x+1 < x+2 < \ldots < x+p$. Moreover, since $\alpha$ is order-decreasing, then $x+i \leq a$ for all $a \in A_i$ ($1 \leq i \leq n$). In particular, $x+1 \leq \min A_1$. Notice that $1 \in A_1$, which implies that $x+1 = 1$, and so $x = 0$. Thus $A_i \alpha = i$ for $1 \leq i \leq p$, as required. \hfill \square

Let

$$\alpha = \begin{pmatrix} A_1 & A_2 & \cdots & A_p \\ 1 & 2 & \cdots & p \end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix} B_1 & B_2 & \cdots & B_p \\ 1 & 2 & \cdots & p \end{pmatrix} \in ODCT_n,$$

then we have the following remark.

Remark 2. For $\alpha, \beta \in ODCT_n$:

- If $|\operatorname{im} \alpha| = |\operatorname{im} \beta|$ then $\operatorname{im} \alpha = \operatorname{im} \beta$;
- If $\ker \alpha = \ker \beta$ then $\alpha = \beta$.

2 Regularity and Green’s relation

For the definitions of the five Green’s relations: $L, R, D, H$ and $J$, we refer the reader to Howie [17] and Higgins [16]. It is well known that on a finite semigroup the relations $D$ and $J$ are equal. The characterizations of Green’s relations on various transformation semigroups have been investigated by many authors, for example see [2, 22, 23, 24, 34]. It is also well known that the semigroup of order-preserving and order-decreasing full transformation $C_n$ is $J$-trivial, see for example [15, 16, 19]. Thus we have the following result.

Theorem 3. Let $ODCT_n$ be as defined in equation (4). Then $ODCT_n$ is $J$-trivial.

Proof. Since the semigroup $ODCT_n$ is a subsemigroup of $C_n$, then $ODCT_n$ is $J$-trivial. \hfill \square

As a consequence, we have the following corollaries.

Now since $ODCT_n$ is $R$ trivial then we have the following.

Corollary 5. An element $\alpha \in ODCT_n$ is regular if and only if $\alpha$ is an idempotent.

3 Starred Green’s relations

Let $S$ be a semigroup. An element $\alpha \in S$ is said to be regular if and only if there exists $\gamma \in S$ such that $\alpha = \alpha \gamma \alpha$. A semigroup $S$ is said to be regular if all the elements of $S$ are regular. On a semigroup $S$, the relation $L^*$ is defined by the rule that $(\alpha, \beta) \in L^*$ if and only if $\alpha$ and $\beta$ are related by Green’s $L$ relation in some over semigroup of $S$. The relation $R^*$ is defined dually and the relation $D^*$ is defined as the join of the relations $L^*$ and $R^*$, where the intersection of the relations $L^*$ and $R^*$ is defined as $H^*$. A semigroup $S$ is said to be right abundant (resp., left abundant) if each $L^*$ - class (resp., each $R^*$ - class) contains an idempotent, and is abundant if each $L^*$ - class and $R^*$ - class of $S$ contains an idempotent. An abundant semigroup in which the set $E(S)$ is a subsemigroup is said to be quasi adequate and if $E(S)$ is commutative then it is said to be adequate, see [21] for more details on adequate semigroups. Many classes of semigroups of transformations were found to be regular and those that are not regular, their regular elements have...
been characterized, for example see [2, 23, 26, 34]. If a semigroup is not regular, then their is a need to investigate the class to which the semigroup belongs. To carry out such investigation one would naturally characterize its starred Green’s relations. In this section we investigate regularity, characterize the starred Green’s relations and show that $\mathcal{ODCT}_n$ is left adequate. As in [17], the relations $\mathcal{L}^*$ and $\mathcal{R}^*$ have the following characterizations:

$$L^* = \{ (\alpha, \beta) : ( \text{ for all } \mu, \lambda \in S^1) \alpha \mu = \alpha \lambda \text{ iff } \beta \mu = \beta \lambda \}$$

and

$$R^* = \{ (\alpha, \beta) : ( \text{ for all } \mu, \lambda \in S^1) \mu \alpha = \lambda \alpha \text{ iff } \mu \beta = \lambda \beta \}.$$  

We now give characterizations of the Starred Green’s relations on $\mathcal{ODCT}_n$ in the theorem below. The proof of the theorem is a simplified version of the proof of Theorem 1 in [33].

**Theorem 6.** Let $\alpha, \beta \in \mathcal{ODCT}_n$ be as expressed in equation (5). Then

(i) $(\alpha, \beta) \in L^*$ if and only if $\text{Im} \alpha = \text{Im} \beta$;

(ii) $(\alpha, \beta) \in R^*$ if and only if $\alpha = \beta$;

(iii) $H^* = R^*$;

(iv) $D^* = L^*$.

**Proof.** (i) Let $\alpha, \beta \in \mathcal{ODCT}_n$ be as expressed in equation (5) and suppose $(\alpha, \beta) \in L^*$. Notice that $\text{Im} \alpha = \{1, \ldots, p\}$. Now consider $\mu = \left(\begin{array}{ccc}1 & 2 & \ldots \{i, \ldots, n\} \\ 1 & 2 & \ldots i \end{array}\right) (1 \leq p \leq i \leq n)$. Then clearly $\mu \in \mathcal{ODCT}_n$ and

$$\alpha \left(\begin{array}{ccc}1 & 2 & \ldots \{i, \ldots, n\} \\ 1 & 2 & \ldots i \end{array}\right) = \alpha \cdot \text{id}_{[n]}$$

if and only if

$$\beta \cdot \left(\begin{array}{ccc}1 & 2 & \ldots \{i, \ldots, n\} \\ 1 & 2 & \ldots i \end{array}\right) = \beta \cdot \text{id}_{[n]} \quad \text{(by equation (6))}$$

which implies that $\text{Im} \alpha \subseteq \text{Im} \beta$. We can similar show that $\text{Im} \beta \subseteq \text{Im} \alpha$. Therefore $\text{Im} \alpha = \text{Im} \beta$.

Conversely, suppose $\text{Im} \alpha = \text{Im} \beta$. Then by [17, Exercise 2.6.17] $\alpha \mathcal{L}^* \beta$ and it follows from definition that $\alpha \mathcal{L}^* \beta$, the result follows.

(ii) Let $\alpha, \beta \in \mathcal{ODCT}_n$ be as expressed in equation (5). Suppose $(\alpha, \beta) \in R^*$. Then $(x, y) \in \ker \alpha$ if and only if $x = y \alpha$ which implies that $\text{Im} \alpha \subseteq \text{Im} \beta$. We can similar show that $\text{Im} \beta \subseteq \text{Im} \alpha$. Therefore $\text{Im} \alpha = \text{Im} \beta$.

Conversely, suppose $\text{Im} \alpha = \text{Im} \beta$. Then by equation (7) $\alpha \mathcal{L}^* \beta$ and it follows from definition that $\alpha \mathcal{L}^* \beta$, the result follows.

(iii) The result follows from (i) and (ii).

(iv) Since $S$ is $R^*$ trivial then $L^* = D^*$.
On the semigroup $ODCT_n$, the relations $D^*$ and $J^*$ are equal as we shall see below. However, we first note the following known result.

**Lemma 7** ([3], Lemma 1.7(3)). Let $a, b$ be elements of a semigroup $S$. Then $b \in J^*(a)$ if and only if there are elements $a_0, a_1, \ldots, a_n \in S$, $x_1, x_2, \ldots, x_n, y_1, y_2, \ldots, y_n \in S^1$ such that $a = a_0$, $b = a_n$ and $(d_i, x_i a_{i-1} y_i) \in D^*$ for $i = 1, 2, \ldots, n$.

Now we prove an analogue of [28, Lemma 2.13].

**Lemma 8.** Let $\alpha, \beta \in ODCT_n$. If $\alpha \in J^*(\beta)$ then $Im \alpha \subseteq Im \beta$.

**Proof.** Let $\alpha \in J^*(\beta)$, $(\alpha, \beta \in ODCT_n)$. Then by Lemma 7 there are elements $\beta_0, \beta_1, \ldots, \beta_n \in ODCT_n$, $\lambda_1, \lambda_2, \ldots, \lambda_n, \mu_1, \mu_2, \ldots, \mu_n \in ODCT^1_n$ such that $\beta = \beta_0, \alpha = \beta_n$ and $(\beta_i, \lambda_i \beta_{i-1} \mu_i) \in D^*$ for $i = 1, 2, \ldots, n$. Thus by Theorem 6(iv), $Im \beta_i = Im \lambda_i \beta_{i-1} \mu_i \subseteq Im \beta_{i-1}$ for all $i = 1, 2, \ldots, n$. This implies that $Im \alpha \subseteq Im \beta$.

**Lemma 9.** On the semigroup $ODCT_n$, $D^* = J^*$.

**Proof.** Let $\alpha, \beta \in ODCT_n$. Notice that $D^* \subseteq J^*$. Thus we only need to show that $J^* \subseteq D^*$. Now let $(\alpha, \beta \in J^*)$, i.e., $\alpha \in J^*(\beta)$ and $\beta \in J^*(\alpha)$. Thus by Lemma 7 $Im \alpha \subseteq Im \beta$ and $Im \beta \subseteq Im \alpha$, as such $Im \alpha = Im \beta$. Therefore by Theorem 6(i) we see that $Im \alpha = Im \beta$.

Now we show in the lemma below that $ODCT_n$ is left abundant.

**Lemma 10.** The semigroup $ODCT_n$ is left abundant.

**Proof.** Let $\alpha \in ODCT_n$ be as expressed in equation (3) and let $L^*_\alpha$ be an $L^*$-class of $\alpha$ in $ODCT_n$. Denote

$$\epsilon = \left( \begin{array}{cccc} 1 & 2 & \ldots & \{p, p+1, \ldots, n\} \\ 1 & 2 & \ldots & p \end{array} \right) \in ODCT_n, \ (1 \leq p \leq n).$$

It is clear that $\epsilon$ is an idempotent in $ODCT_n$, moreover $Im \alpha = Im \epsilon$ and so by Theorem 6(i) we see that $(\alpha, \epsilon) \in L^*$ which means $\epsilon \in L^*_\alpha$. Since $L^*_\alpha$ is an arbitrary $L^*$-class of $\alpha$ in $ODCT_n$, then $ODCT_n$ is left abundant, as required.

**Remark 11.** In contrast with [3], Lemma 1.20], the semigroup $ODCT_n$ is not right abundant for $n \geq 3$.

For a counterexample, consider $\alpha = \left( \begin{array}{cc} \{1, 2\} & 3 \\ 1 & 2 \end{array} \right) \in ODCT_3$. It is clear that

$$R^*_\alpha = \left\{ \left( \begin{array}{cc} \{1, 2\} & 3 \\ 1 & 2 \end{array} \right) \right\}$$

has no idempotent.

However, the semigroup $ODCT_n$ is right abundant for $1 \leq n \leq 2$ which is also in contrast with [3], Remark 1.21].

### 4 Rank of $ODCT_n$

Let $S$ be a semigroup and $A$ be any nonempty subset of $S$. The subsemigroup generated by $A$ is the smallest subsemigroup of $S$ containing $A$ and is denoted by $\langle A \rangle$. If there exists a finite subset $A$ of a semigroup $S$ with $\langle A \rangle = S$, then $S$ is said to be a **finitely generated semigroup**. The rank of a finitely generated semigroup $S$ is defined by

$$\text{rank}(S) = \min\{|A| : \langle A \rangle = S\}.$$
The ranks of many semigroups of transformations have been investigated over the years by many authors, see for example [3, 9, 13, 4, 29]. In particular, Kemal [27] obtained the ranks of the semigroups $OCT_n$ and $ORCT_n$, respectively. This study was extended to obtain the ranks of the two sided ideals of $OCT_n$ and $ORCT_n$, respectively by Leyla [5]. However, the rank of $ODCT_n$ does not seem to have been investigated and in this section we investigate it.

Now let $ORCT_n$ denote the semigroup of all order preserving or order reversing full contractions, and let $\text{Reg}(ORCT_n)$ be the collection of regular elements of $ORCT_n$. Then, we first note the following result about idempotents in $ORCT_n$ from [33].

\textbf{Lemma 12} ([33], Lemma 13). Let $\epsilon$ be an idempotent element in $(ORCT_n)$. Then $\epsilon$ can be expressed as

$$
\epsilon = (\begin{array}{cccc}
1 & 2 & \cdots & \{p, p+1, \ldots, n\} \\
1 & 2 & \cdots & p
\end{array}) \quad (1 \leq p \leq n).
$$

We now prove the following lemma which is crucial to the main result.

\textbf{Lemma 13.} Every $\epsilon \in E(ODCT_n)$ can be expressed as

$$
\epsilon = (\begin{array}{cccc}
1 & 2 & \cdots & \{k, k+1, \ldots, n\} \\
1 & 2 & \cdots & k
\end{array}) \quad (1 \leq k, p \leq n).
$$

\textit{Proof.} The proof follows from Lemma 12 and Lemma 1. \hfill \square

We show in the next theorem that, the collection of all idempotents in $ODCT_n$ i.e., $E(ODCT_n)$ is a semilattice.

\textbf{Theorem 14.} $E(ODCT_n)$ is a semilattice.

\textit{Proof.} Let $\epsilon, \eta \in E(ODCT_n)$. Then by Lemma 13 we may denote $\epsilon$ and $\eta$ by

$$
\epsilon = (\begin{array}{cccc}
1 & 2 & \cdots & \{k, k+1, \ldots, n\} \\
1 & 2 & \cdots & k
\end{array}) \quad \text{and} \quad \eta = (\begin{array}{cccc}
1 & 2 & \cdots & \{p, p+1, \ldots, n\} \\
1 & 2 & \cdots & p
\end{array}) \quad (1 \leq k, p \leq n).
$$

Thus we have two cases to consider:

If $k \leq p$. Then

$$
\epsilon \eta = (\begin{array}{cccc}
1 & 2 & \cdots & \{k, k+1, \ldots, n\} \\
1 & 2 & \cdots & k
\end{array}) = \eta \epsilon = \epsilon \in E(ODCT_n).
$$

If $p < k$. Then

$$
\epsilon \eta = (\begin{array}{cccc}
1 & 2 & \cdots & \{p, p+1, \ldots, n\} \\
1 & 2 & \cdots & p
\end{array}) = \eta \epsilon = \eta \in E(ODCT_n).
$$

Thus $E(ODCT_n)$ is a semilattice. \hfill \square

Now by Theorem 14 and Lemma 10, we readily have the following result.

\textbf{Theorem 15.} Let $ODCT_n$ be as defined in equation (3). Then $ODCT_n$ is left adequate.

Next, we state the following well known result from [7] as a lemma below.

\textbf{Lemma 16.} In a finite $J$ trivial semigroup $S$, every minimal generating set is (unique) minimum.

Let $G_p = \{\alpha \in ODCT_n : |\text{Im} \alpha| = p\}$ and $K_p = \{\alpha \in ODCT_n : |\text{Im} \alpha| \leq p\}$. It is worth noting that $K_p = G_1 \cup G_2 \cup \ldots \cup G_p$ ($1 \leq p \leq n$). Now we have the following lemma.

\textbf{Lemma 17.} For $1 \leq p \leq n - 2$, $G_p \subseteq (G_{p+1})$. 

6
Proof. Let $\alpha \in G_p$, then by Lemma 11 we may let $\alpha = \begin{pmatrix} A_1 & A_2 & \cdots & A_p \end{pmatrix}$, where $1 \leq p \leq n - 2$. Next now let $A_p' \cup A_p'' = A_p$ with $A_p' \neq \emptyset, A_p'' \neq \emptyset, A_p' \cap A_p'' = \emptyset$ and $A_p' < A_p''$. Now denote $\delta$ and $\rho$ as:

$$\delta = \begin{pmatrix} A_1 & A_2 & \cdots & A_{p-1} & A_p' & A_p'' \end{pmatrix} \quad \text{and} \quad \rho = \begin{pmatrix} 1 & 2 & \cdots & p-1 & \{p,p+1\} & \{p+2,\ldots,n\} \\ 1 & 2 & \cdots & p-1 & p & p+1 \end{pmatrix}.$$  

Notice that $\delta, \rho \in G_{p+1}$. It is easy to see that $\alpha = \delta \rho \in \langle G_{p+1} \rangle$. Hence $G_p \subseteq \langle G_{p+1} \rangle$.

As a consequence we have the following Corollary.

**Corollary 18.** For $1 \leq r \leq n-1$, $G_r \subseteq \langle G_{n-1} \rangle$.

**Proof.** Suppose $1 \leq r \leq n-1$, then by Lemma 17 we see that $G_r \subseteq \langle G_{r+1} \rangle$ and similarly $G_{r+1} \subseteq \langle G_{r+2} \rangle$ which implies that $\langle G_r \rangle \subseteq \langle G_{r+2} \rangle$. Therefore $G_r \subseteq \langle G_{r+1} \rangle \subseteq \langle G_{r+2} \rangle$. If we continue in this fashion we see that $G_r \subseteq \langle G_{r+1} \rangle \subseteq \langle G_{r+2} \rangle \subseteq \ldots \subseteq \langle G_{n-2} \rangle \subseteq \langle G_{n-1} \rangle$, as required.

**Lemma 19.** In $\text{ODCT}_n$, $|G_{n-1}| = n - 1$.

**Proof.** Notice that if $\alpha \in G_{n-1}$ then $\alpha$ is of the form $\alpha = \begin{pmatrix} A_1 & A_2 & \cdots & A_{n-1} \end{pmatrix}$, where $A_i < A_j$ if and only if $i < j$. It is now clear that order of $G_{n-1}$ is equal to the number of subsets of the set $[n]$ of the form $\{i, i+1\} (1 \leq i \leq n-1)$ which is $n - 1$.

The following lemma gives us the rank of $\text{ODCT}_n \setminus \{id_n\}$.

**Lemma 20.** In $\text{ODCT}_n$, rank $(K_{n-1}) = n - 1$.

**Proof.** To prove that the rank $(K_{n-1}) = n - 1$, it is enough to show that $G_{n-1}$ is a minimal generating set of $K_{n-1}$, i.e., $K_{n-1} = \langle G_{n-1} \rangle$ and $\langle G_{n-1} \setminus \{\tau\} \rangle \neq K_{n-1}$ for any $\tau \in G_{n-1}$. Notice that by Corollary 18 $G_1 \subseteq \langle G_{n-1} \rangle, G_2 \subseteq \langle G_{n-1} \rangle, \ldots, G_{n-1} \subseteq \langle G_{n-1} \rangle$. Thus it easily follows that $G_1 \cup G_2 \cup \ldots \cup G_{n-1} \subseteq \langle G_{n-1} \rangle$, i.e., $K_{n-1} \subseteq G_{n-1}$.

Notice that

$$G_{n-1} = \left\{ \begin{pmatrix} 1,2 & 3 & \cdots & n \end{pmatrix} \begin{pmatrix} 1,2,3 & 4 & \cdots & n \end{pmatrix} \cdots \begin{pmatrix} 1,2,3 & \cdots & n-2 & \{n-1,n\} \end{pmatrix} \right\}. $$

Take $\tau_i = \begin{pmatrix} 1 & 2 & \cdots & \{i,i+1\} & \cdots & n-2 & n-1 & n \\ 1 & 2 & \cdots & i & \cdots & n-3 & n-2 & n-1 \end{pmatrix} \in G_{n-1}$ for $i = 1, \ldots, n-1$. Then one can easily verify that for any $\alpha, \beta \in G_{n-1} \setminus \{\tau_i\}$, $h(\alpha \beta) < n-1$, $h(\tau_i \alpha) < n-1$, $h(\alpha \tau_i) < n-1$ and moreover, $\alpha \tau_i = \alpha$ for all $\alpha \in G_{n-1}$. Thus $G_{n-1}$ is a minimal generating set for $K_{n-1}$. Thus since $S$ is a finite $J$ trivial semigroup then by Lemma 14 $G_{n-1}$ is the (unique) minimum generating set for $K_{n-1}$.

Finally the rank of $\text{ODCT}_n$ is given in the theorem below.

**Theorem 21.** Let $\text{ODCT}_n$ be as defined in equation 8. Then rank $(\text{ODCT}_n) = n$.

**Proof.** Notice that $K_{n-1} = \text{ODCT}_n \setminus \{id_n\}$. Therefore the rank $(\text{ODCT}_n) = \text{rank} (K_{n-1}) + 1 = n$, as required.
5 Natural Partial Order on the semigroup $OCT_n$

Let $S$ be a semigroup and $\alpha, \beta \in S$. Define a relation $\leq$ on a semigroup $S$ by: $\alpha \leq \beta$ ($\alpha, \beta \in S$) if and only if there exist $\lambda, \mu \in S^1$ such that $\alpha = \lambda \beta = \beta \mu$ and $\alpha = \alpha \mu$. This relation is known to be the natural partial order on a semigroup $S$. If $S$ is regular then $\alpha \leq \beta$ if and only if $\alpha = \epsilon \beta = \beta \eta$ for some $\epsilon, \eta \in E(S)$, and if $S$ is a semilattice of idempotents then $\epsilon \leq \eta$ if and only if $\epsilon = \epsilon \eta = \eta \epsilon$ for some $\epsilon, \eta \in E(S)$. Partial order relations on various semigroups of the partial transformations have been investigated by many authors, see for example [6] [18] [21] [20]. It is worth noting that the semigroup $OCT_n$ is not regular (see [22]). In this section, we characterize the partial order relation defined above on the semigroups $OCT_n$ and $ODCT_n$, respectively.

Let $\alpha, \beta$ be as expressed in equation (4). Consider

$$ \alpha \beta^{-1} = \{(x, y) \in [n] \times [n] : x \beta = y \alpha\}, \quad \text{(8)} $$

$$ \alpha \alpha^{-1} = \{(x, y) \in [n] \times [n] : x \alpha = y \alpha\}. \quad \text{(9)} $$

Before we begin our investigation we first acknowledge the following known result from [21].

**Lemma 22** ([21], Theorem 2). Let $\alpha, \beta \in P_n$. Then $\alpha \leq \beta$ if and only if $\text{dom } \alpha \subseteq \text{dom } \beta$, $\alpha \beta^{-1} \subseteq \alpha \alpha^{-1}$ and $\beta \beta^{-1} \cap (\text{dom } \beta \times \text{dom } \alpha) \subseteq \alpha \alpha^{-1}$.

Now we have the following lemma.

**Lemma 23.** Let $\alpha, \beta \in OCT_n$. If $\alpha \beta^{-1} \subseteq \alpha \alpha^{-1}$. Then $y \beta^{-1} \subseteq y \alpha^{-1}$ for all $y \in \alpha$.

**Proof.** Suppose $\alpha \beta^{-1} \subseteq \alpha \alpha^{-1}$, $y \in \alpha$ and let $x \in y \beta^{-1}$. Then there exists $b \in [n]$ such that $b \alpha = y$ and $y = x \beta$, i.e., $b \alpha = x \beta$, which imply $(x, b) \in \alpha \beta^{-1}$. Thus, by our assumption, we have $(x, b) \in \alpha \alpha^{-1}$, so that $x \alpha = b \alpha = y$ which implies that $\alpha \beta^{-1} \subseteq \alpha \alpha^{-1}$. Hence $x \in y \alpha^{-1}$, as required.

Let $\alpha$ in $OCT_n$ be of rank 1. Then we have the following.

**Lemma 24.** Let $\alpha, \beta \in OCT_n$ be such that $\alpha = \left( \begin{array}{c} [n] \\ x \end{array} \right)$. Then $\alpha \leq \beta$ if and only if $x \in \text{im } \beta$.

**Proof.** Let $\alpha, \beta \in OCT_n$, where $\alpha = \left( \begin{array}{c} [n] \\ x \end{array} \right)$. Suppose $\alpha \leq \beta$, i.e., there exist $\lambda, \mu \in OCT_n$ such that $\alpha = \lambda \beta = \beta \mu$ and $\alpha \mu = \alpha$. Notice that $\alpha = \lambda \beta$. It is easy to see that $\text{im } \alpha \subseteq \text{im } \beta$. Therefore $x \in \text{im } \beta$.

Conversely, suppose $x \in \text{im } \beta$. Define $\lambda = \left( \begin{array}{c} [n] \\ y \end{array} \right)$ where $y \in x \beta^{-1}$ and $\mu = \alpha$. Thus, it follows that $\alpha = \lambda \beta = \beta \mu$ and $\alpha \mu = \alpha$, and therefore $\alpha \leq \beta$.

Now if $\alpha$ is of rank 2, we have the following.

**Lemma 25.** Let $\alpha, \beta \in OCT_n$ be such that $\alpha = \left( \begin{array}{cc} A_1 & A_2 \\ x + 1 & x + 2 \end{array} \right)$. Then $\alpha \leq \beta$ if and only if $\text{im } \alpha \subseteq \text{im } \beta$ and $(\max A_1) \beta = x + 1$ and $(\min A_2) \beta = x + 2$.

**Proof.** Let $\alpha, \beta \in OCT_n$, where $\alpha = \left( \begin{array}{cc} A_1 & A_2 \\ x + 1 & x + 2 \end{array} \right)$. Suppose $\alpha \leq \beta$ i.e., there exist $\lambda, \mu \in OCT_n$ such that $\alpha = \lambda \beta = \beta \mu$ and $\alpha \mu = \alpha$. Since $\alpha = \lambda \beta$ then obviously $\text{im } \alpha \subseteq \text{im } \beta$. So $\text{im } \alpha \subseteq \text{im } \beta$. Suppose by way of contradiction that $(\max A_1) \beta = k \neq x + 1$ for some $k \in \beta$. Since $\beta$ is order-preserving then we have that $x + 1 < k < x + 2$. (10)

Notice that $\alpha = \lambda \beta = \beta \mu$ and $\alpha \mu = \alpha$, for some $\lambda, \mu \in OCT_n$. Now $\alpha = \beta \mu$ ensure that $k \mu = x + 1$ and $(x+i)\mu = x + i$ for all $i \in \{1, 2\}$. Thus $|x + 2| - (x + 1) = |x + 2| - (x + 1) \leq (x + 2) - (x + 1)$ which contradicts equation (10). Hence $(\max A_1) \beta = x + 1$. In a similar way, one can easily show that $(\min A_2) \beta = x + 2$. 

8
Conversely, suppose that condition (i) and (ii) holds. Define $\lambda$ as:

$$ y\lambda = \begin{cases} \max A_1, & \text{if } y \in A_1; \\ \min A_2, & \text{if } y \in A_2. \end{cases} $$

and

$$ \mu = \left( \begin{array}{cc} \{1, \ldots, x+1\} & \{x+2, \ldots, n\} \\ x+1 & x+2 \end{array} \right) \in \mathcal{OCT}_n. $$

We now show that $\lambda \in \mathcal{OCT}_n$. Notice that if $y_1, y_2 \in A_1$ then

$$ |y_1\lambda - y_2\lambda| = |\max A_1 - \max A_1| = |y_1 - y_1| \leq |y_1 - y_2|. $$

Now if $y_1, y_2 \in A_2$. Then

$$ |y_1\lambda - y_2\lambda| = |\min A_2 - \min A_2| = |y_2 - y_2| \leq |y_1 - y_2|. $$

Finally, if $y_1 \in A_1$ and $y_2 \in A_2$, then

$$ |y_1\lambda - y_2\lambda| = |\max A_1 - \min A_2| = |a - b| \text{ for all } a \in A_1, b \in A_2. $$

In particular, $|y_1\lambda - y_2\lambda| \leq |y_1 - y_2|$. Hence $\lambda$ is a contraction and since $A_1 < A_2$ then $\lambda \in \mathcal{OCT}_n$. It is now easy to see that $\alpha = \lambda \beta = \beta \mu$ and $\alpha \mu = \alpha$. Thus $\alpha \leq \beta$, as required. □

Next let $\alpha \in \mathcal{OCT}_n$ be of rank $p$. Then we have the following.

**Theorem 26.** Let $\alpha, \beta \in \mathcal{OCT}_n$ be such that $\alpha = \left( \begin{array}{cccc} A_1 & A_2 & \ldots & A_{p-1} \\ x+1 & x+2 & \ldots & x+p-1 \end{array} \right)$. Then $\alpha \leq \beta$ if and only if

(i) $\text{im } \alpha \subseteq \text{im } \beta$;

(ii) $(x+i)\beta^{-1} = A_i$ for all $i \in \{2, 3, \ldots, p-1\}$ and

(iii) $(\max A_1)\beta = x+1$ and $(\min A_p)\beta = x+p$.

**Proof.** (i) Let $\alpha, \beta \in \mathcal{OCT}_n$, where $\alpha = \left( \begin{array}{cccc} A_1 & A_2 & \ldots & A_{p-1} \\ x+1 & x+2 & \ldots & x+p-1 \end{array} \right)$, Suppose $\alpha \leq \beta$. Then (i) follows obviously from the proof of Theorem 25(i).

(ii) Since $\mathcal{OCT}_n \subseteq \mathcal{P}_n$ then by Lemma 22 we have that $\alpha \beta^{-1} \subseteq \alpha \alpha^{-1}$. Moreover, by Lemma 23 we have that $(x+i)\beta^{-1} \subseteq A_i$ for all $i \in \{1, 2, \ldots, p\}$. Suppose by way of contradiction that $(x+i)\beta^{-1} \neq A_i$, i.e., $(x+i)\beta^{-1} \not\subseteq A_i$ for some $i \in \{2, 3, \ldots, p-1\}$. Let $a \in A_i \setminus (x+i)\beta^{-1}$. Then there exists $b \in \mu \beta \setminus \{x+i\}$ such that $a \in b\beta^{-1}$. Since $\alpha = \beta \mu$ then $b \in \text{dom } \mu$ and $b\mu = x+i$ for some $i \in \{2, 3, \ldots, p-1\}$. Since $\alpha = \alpha \mu$ then $x+i = (x+i)\mu$ for all $i \in \{2, 3, \ldots, p-1\}$. There are two cases to consider about $b$.

Case 1: If $x+i < b \leq x+i+1$. Then

$$ |(x+i+1) - b| < |(x+i+1) - (x+i)|. $$

Now $|(x+i+1) - (x+i)| = |(x+i+1)\mu - b\mu| \leq |(x+i+1) - b|$ which contradicts equation 11.

Case 2: If $x+i-1 \leq b < x+i$. Then

$$ |b - (x+i-1)| < |(x+i) - (x+i-1)|. $$

Now $|(x+i) - (x+i-1)| = |b\mu - (x+i-1)\mu| \leq |b - (x+i-1)|$ which contradicts equation 12. So we have $(x+i)\beta^{-1} = A_i$ for some $i \in \{2, 3, \ldots, p-1\}$. 

9
(iii) Suppose by way of contradiction that \((\max A_1)\beta = k \neq x + 1\) for some \(k \in \im\beta\). Since \(\beta\) is order-preserving, we have that
\[
x + 1 < k < x + 2.
\]
\[
\tag{13}
\]
Notice that \(\alpha = \lambda\beta = \beta\mu\) and \(\alpha\mu = \alpha\), for some \(\lambda, \mu \in \OCT_n\). Now \(\alpha = \beta\mu\) ensure that \(k\mu = x + 1\) and \((x + i)\mu = x + i\) for all \(i \in \{1, 2, \ldots, p\}\). Thus \(|(x + 2) - (x + 1)| = |(x + 2)\mu - k\mu| \leq |(x + 2) - k|\) which contradicts equation (13). Hence \((\max A_1)\beta = x + 1\). Similarly, one can show that \((\min A_1)\beta = x + p\).

Conversely, suppose that conditions (i) - (iii) holds. Define \(\lambda\) as:
\[
y\lambda = \begin{cases} 
\max A_1, & \text{if } y \in A_1; \\
y, & \text{if } y \in A_2 \cup \ldots \cup A_{p-1}; \\
\min A_p, & \text{if } y \in A_p. 
\end{cases}
\]
and \(\mu = \left(\begin{array}{c} \{1, \ldots, x + 1\} \\ \{x + 2 \ldots x + p - 1\} \\ \{x + p, \ldots, n\} \end{array}\right) \in \OCT_n\). Then \(\lambda \in \OCT_n\). To see this, notice that if \(y_1, y_2 \in A_1\) then
\[
|y_1\lambda - y_2\lambda| = |\max A_1 - \max A_1| = |y_1 - y_1| \leq |y_1 - y_2|.
\]
Now if \(y_1, y_2 \in A_p\). Then
\[
|y_1\lambda - y_2\lambda| = |\min A_p - \min A_p| = |y_p - y_p| \leq |y_1 - y_2|.
\]
Also, if \(y_1, y_2 \in A_i\) for all \(i \in \{2, \ldots, p - 1\}\). Then \(|y_1\lambda - y_2\lambda| = |y_1 - y_2| \leq |y_1 - y_2|\).

Finally, if \(y_1 \in A_1\) and \(y_2 \in A_p\), then \(|y_1\lambda - y_2\lambda| = |\max A_1 - \min A_p| = |a - b|\) for all \(a \in A_1, b \in A_p\). In particular
\[
|y_1\lambda - y_2\lambda| \leq |y_1 - y_2|.
\]
Hence \(\lambda\) is a contraction and since \(A_i < A_j\) if and only if \(i < j\) then \(\lambda \in \OCT_n\). It is now easy to see that \(\alpha = \lambda\beta = \beta\mu\) and \(\alpha\mu = \alpha\). Thus \(\alpha \leq \beta\).

\[
\square
\]

Now we illustrate the constructions behind the proof of Theorem 26 with an example.

**Example 27.** For \(n = 10\).
\[
\alpha = \left(\begin{array}{cccccc}
\{1, 2, 3\} & \{4, 5\} & 6 & \{7, 8\} & \{9, 10\} \\
4 & 5 & 6 & 7 & 8
\end{array}\right)
\]
and
\[
\beta_1 = \left(\begin{array}{cccccc}
\{1, 2\} & \{3, 4, 5\} & 6 & \{7, 8\} & 9 & 10 \\
3 & 4 & 5 & 6 & 7 & 8 & 9
\end{array}\right)
\].

Then it is easy to check that \(\alpha\) and \(\beta\) satisfies the conditions (i) - (iii) of Theorem 26. Now denote
\[
\lambda = \left(\begin{array}{cccccc}
\{1, 2, 3\} & 4 & 5 & 6 & 7 & 8 & \{9, 10\} \\
3 & 4 & 5 & 6 & 7 & 8 & 9
\end{array}\right)
\]
and
\[
\mu = \left(\begin{array}{cccccc}
\{1, 2, 3, 4\} & 5 & 6 & 7 & 8 & \{8, 9, 10\} \\
4 & 5 & 6 & 7 & 8 & 8
\end{array}\right)
\].

One can easily check that \(\alpha = \lambda\beta = \beta\mu\) and \(\alpha\mu = \alpha\). Thus \(\alpha \leq \beta_1\).

It worth noting that if
\[ \beta_2 = \begin{pmatrix} \{1, 2\} & 3 & 4 & 5 & \{6, 7, 8\} & 9 & 10 \\ 3 & 4 & 5 & 6 & 7 & 8 & 9 \end{pmatrix}. \]

Then clearly \( \alpha \notin \beta_2 \). To see this, suppose that there exists \( \mu \in OCT_n \) such that \( \alpha = \beta_2 \mu \). Then notice that
\[ 6 = (6)\alpha = (6)\beta_2 \mu \text{ and } 8 = (9)\alpha = (9)\beta_2 \mu = (8)\mu. \]

Thus \( |8 - 6| = |(8)\mu - (7)\mu| \notin |8 - 7| \), which is a contradiction. Therefore \( \alpha \notin \beta_2 \) because \( \beta_2 \) does not satisfy condition (ii) in Theorem 26.

We now deduce a characterization of partial order relation on the subsemigroup \( ODCT_n \) from the results obtained for the semigroup \( OCT_n \). But before then, it is worth noting that the element \( \left( \begin{array}{c} n \\ x \end{array} \right) \) is the only element of rank 1 in \( \in ODCT_n \). Thus we have the following result.

**Corollary 28.** Let \( \alpha = \left( \begin{array}{c} n \\ 1 \end{array} \right) \in ODCT_n \). Then \( \alpha \leq \beta \) for all \( \beta \in ODCT_n \).

**Proof.** Let \( \alpha = \left( \begin{array}{c} n \\ 1 \end{array} \right) \) and \( \beta = \left( \begin{array}{ccc} B_1 & \ldots & B_p \\ 1 & \ldots & p \end{array} \right) \). Denote \( \lambda = \mu = \left( \begin{array}{c} n \\ 1 \end{array} \right) \). Therefore \( \alpha = \lambda \beta = \beta \mu \) and \( \alpha \mu = \alpha \). Thus \( \alpha \leq \beta \). \(\square\)

We next deduce a characterization of partial order relation on \( ODCT_n \) (if \( \alpha \) is of rank 2) from Theorem 25.

**Corollary 29.** Let \( \alpha, \beta \in ODCT_n \) be such that \( \alpha = \left( \begin{array}{cc} A_1 & A_2 \\ 1 & 2 \end{array} \right) \). Then \( \alpha \leq \beta \) if and only if \( (\max A_1) \beta = 1 \) and \( (\min A_2) \beta = 2 \).

**Proof.** Let \( \alpha, \beta \in ODCT_n \), where \( \alpha = \left( \begin{array}{cc} A_1 & A_2 \\ 1 & 2 \end{array} \right) \). Suppose \( \alpha \leq \beta \). Since \( ODCT_n \subset OCT_n \) then \( \alpha, \beta \in OCT_n \). Thus by Theorem 25 we have \( \text{im} \alpha \subseteq \text{im} \beta \) and \( (\max A_1) \beta = 1 \) and \( (\min A_2) \beta = 2 \). Notice that \( \text{im} \alpha = \{1, 2\} \subseteq \text{im} \beta \) (\( p \geq 2 \)) always holds by Lemma 1.

Conversely, \( (\max A_1) \beta = 1 \) and \( (\min A_2) \beta = 2 \). Then clearly, \( \text{im} \alpha = \{1, 2\} \subset \text{im} \beta = \{1, 2, \ldots, p\} \) (\( p \geq 2 \)) and \( (\max A_1) \beta = 1 + 0 \) and \( (\min A_2) \beta = 2 + 0 \), and therefore by Theorem 25 we have \( \alpha \leq \beta \), as required. \(\square\)

Now we have the following corollary and its proof follows from Theorem 5 which is similar to the proof of Corollary 29 thus we omit it.

**Corollary 30.** Let \( \alpha, \beta \in ODCT_n \) be such that \( \alpha = \left( \begin{array}{cc} A_1 & \ldots & A_p \\ 1 & \ldots & p \end{array} \right) \), (1 \( \leq p \leq n \)). Then \( \alpha \leq \beta \) if and only if
\begin{itemize}
  \item [(i)] \( (\max A_1) \beta = 1 \) and \( (\min A_p) \beta = p \); and
  \item [(ii)] \( (i)\beta^{-1} = A_i \) for some \( i \in \{2, 3, \ldots, p - 1\} \).
\end{itemize}
