SOME REMARKS ON DECOMPOSITION THEOREM
FOR PROPER KÄHLER MORPHISMS

MORIHIKO SAITO

Abstract. We explain a correct proof of the decomposition theorem for direct images of constant sheaves by proper Kähler morphisms of complex manifolds.

Introduction

Decomposition theorem for direct images of constant Hodge modules under proper Kähler morphisms of complex manifolds was announced in [Sa 90b, Thm. 0.5]. There was, however, some misstatement in the proof. In this paper we explain a correct proof of the following.

Theorem 1. Let \( f : X \to Y \) be a proper Kähler morphism of connected complex manifolds with \( \dim X = n \). Then the Hodge filtration \( F \) on the direct image as a filtered \( \mathcal{D} \)-module \( f^\bullet_*(\mathcal{O}_X, F) \) is strict, the cohomological direct images

\[
\mathcal{H}^j f_*(\mathcal{O}_X, F, \mathbb{R} X[n]) := (\mathcal{H}^j f^\bullet_*(\mathcal{O}_X, F), p^\bullet f_\bullet \mathbb{R} X[n]) \quad (j \in \mathbb{Z})
\]

are Hodge modules of weight \( j - n \), we have the hard Lefschetz property

\[
\ell^k : \mathcal{H}^{-k} f_*(\mathcal{O}_X, F, \mathbb{R} X[n]) \xrightarrow{\sim} \mathcal{H}^k f_*(\mathcal{O}_X, F, \mathbb{R} X[n]) (k) \quad (k > 0),
\]

and the primitive part is polarized with sign given as in [Sa 88, 5.3.1 and 5.4.1]. Here \( \ell \) is the cohomology class of a relative Kähler class in \( H^2(X, \mathbb{R}(1)) \), and \( \text{Gr}_{p}^F \mathcal{O}_X = 0 \ (p \neq 0) \).

This implies the decomposition theorem using [De 68] together with the strict support decomposition. The difficulty in the proof of Theorem 1 is that it is not easy to deduce the hard Lefschetz property (1) from the one for the composition with a desingularization. We may assume that the latter is a composition of blow-ups along smooth centers, see [W/suppress l 09]. In the constant Hodge module case, this situation can be utilized quite effectively, since we can easily apply the key lemma [Sa 88, Lem. 5.2.15] to the restriction and Gysin morphisms between the blow-up and the exceptional divisor at each step. (It does not seem trivial to generalize this to the non-constant case, since extension classes of general Hodge modules can be rather complicated, see also Remark 2.2b below.)

As a corollary we get the following (extending the main theorem in [FFS 14] to the proper Kähler case).

Theorem 2 (see [Fn 22, Thm 2.5]). Let \((X, D)\) be an analytic simple normal crossing pair with \( D \) reduced. Let \( f : X \to Y \) be a proper morphism to a complex manifold \( Y \). Assume \( f \) is Kähler on each irreducible component of \( X \). Then we have the weight spectral sequence

\[
E_1^{-q,i+q} = \bigoplus_{k+l=n+q+1} R^q f_* \omega_{D[k,l]/Y} \Rightarrow R^q f_* \omega_{X/Y}(D),
\]

degenerating at \( E_2 \), and its \( E_1 \)-differential \( d_1 \) splits so that the \( E_2^{-q,i+q} \) are direct factors of \( E_1^{-q,i+q} \).

In Section 1 we prove Theorem 1 with \( X \) replaced by an embedded resolution shrinking \( Y \) if necessary. This implies the theorem in the general case except the hard Lefschetz property and the induced polarization on the \( \ell \)-primitive part. In Section 2 we prove the hard Lefschetz property after reviewing some basics of Gysin and restriction morphisms associated to blow-ups of complex manifolds along smooth centers.
We thank O. Fujino for his interest in this subject. This work is partially supported by JSPS Kakenhi 15K04816.

1. Proof of Theorem 1 for embedded resolutions

In this section we prove Theorem 1 with $X$ replaced by an embedded resolution shrinking $Y$ if necessary. This implies the theorem in the general case except the hard Lefschetz property and the induced polarization on the $\ell$-primitive part.

1.1. Level 0 Hodge modules of normal crossing type. Let $X$ be a complex manifold of pure dimension $n$. We say that a polarizable $\mathbb{R}$-Hodge module $\mathcal{M} = ((M, F), K)$ with strict support $X$ (that is, $K$ is an intersection complex on $X$ with local system coefficients, see [BBD 82]) is a level 0 Hodge module of normal crossing type with singular locus $\text{Sing} \mathcal{M}$ contained in $D \subset X$ if $D$ is a divisor with simple normal crossings and the restriction of $\mathcal{M}$ to $U := X \setminus D$ corresponds to a variation of Hodge structure of level 0 and type $(0, 0)$ (in particular, $\mathcal{M}$ has weight $n$). The last condition means that the Hodge filtration $F$ is trivial on $U$, more precisely, $\text{Gr}^F_p M|_U = 0$ for $p \neq 0$. The underlying local system $K[-n]|_U$ is an orthogonal representation (by a polarization) with semisimple local monodromies of finite orders around the irreducible components of $D$. Note that the constant Hodge module $((O_X, F), \mathbb{R}[n])$ is a level 0 Hodge module of normal crossing type with weight $n$, where $D = \emptyset$.

Let $\mathcal{M}$ be a level 0 Hodge module of normal crossing type with $\text{Sing} \mathcal{M} \subset D$. Let $f : X \to Y$ be a proper Kähler morphism of complex manifolds. Let $p \in f(X)$, and $g_i (i \in [1, r])$ be holomorphic functions on $Y$ (replacing $Y$ with a neighborhood of $p$ if necessary) such that

$$\bigcap_{i=1}^r g_i^{-1}(0) \cap f(X) = \{ p \},$$

where we may have $r > \dim f(X)$. Consider the condition

$$D \supset \bigcup_{i=1}^r h_i^{-1}(0),$$

with $h_i := f^* g_i$ (replacing $D$ and taking an embedded resolution). Here the divisors $h_i^{-1}(0)$ have simple normal crossings, since they are contained in a divisor with simple normal crossings. Let $\ell$ be the cohomology class of a relative Kähler form for $f$. We have the following.

\textbf{Theorem 1.1.} In the above notation, the direct image as a filtered $D$-module $f_*^D (M, F)$ is strict, and the cohomological direct images $\mathcal{H}^j f_*^D \mathcal{M} (j \in \mathbb{Z})$ are Hodge modules of weight $j - n$, where (1.1.2) is not assumed. If (1.1.2) is satisfied, then, replacing $Y$ with a neighborhood of $p$ if necessary, we have the hard Lefschetz property for the action of $\ell$ together with the induced polarization on the $\ell$-primitive part.

\textit{Proof.} We argue by induction on $\dim f(X)$. If $f(X) = \{ p \}$, we may assume $Y = \{ p \}$. Hodge theory for unitary local systems with semi-simple local monodromies of finite orders is an easy case of [CKS 87], [KK 86], [KK 87], and is more or less well-known.

Assume $\dim f(X) > 0$. Applying [Sa 90a, Thm. 3.3–4], the hypothesis that $\mathcal{M}$ is a level 0 Hodge module of normal crossing type is preserved by taking the $N$-primitive part of the $W$-graded pieces of nearby and vanishing cycle functors $P_N \text{Gr}^W_k \psi_{h_1}, P_N \text{Gr}^W_k \varphi_{h_1}$ up to Tate twists. Assuming (1.1.2), and applying [Sa 88] Prop.3.3.17, Prop.4.2.2, and Cor.4.2.4 and the inductive hypothesis, we then see that

$$P_N \text{Gr}^W_k \psi_{g_1} \mathcal{H}^j f_* \mathcal{M}, \quad P_N \text{Gr}^W_k \varphi_{g_1} \mathcal{H}^j f_* \mathcal{M} \quad (k \in \mathbb{Z})$$

are Hodge modules of weight $k$ (using the weight spectral sequence), and get the strictness of the Hodge filtration $F$ on the direct image together with the hard Lefschetz property and the induced polarization on the $(\ell, N)$-bi-primitive part, replacing $Y$ with a neighborhood
of \( p \) if necessary. (Note that the vanishing cycle functor is the identity for objects whose supports are contained in the zero-locus of the function.)

Here we can apply the above argument by replacing \( \psi_{g_1}, \varphi_{g_1,1} \) with \( \psi_{g_1-c}, \varphi_{g_1-c,1} \) for \( 0 < |c| \ll 1 \). (Note that any intersections of irreducible components of \( D \), which are not contained in \( h^{-1}_1(0) \), intersects \( h^{-1}_1(c) \) transversally for \( 0 < |c| \ll 1 \).) This can be used to show that we have the induced polarization on the \( \ell \)-primitive part. Indeed, if a strict support \( Z \) of a direct factor of \( H^{1}\tilde{f}_* M \) is not contained in \( g_1^{-1}(0) \) and \( Z \cap g_1^{-1}(0) \neq \emptyset \), then we take \( c \) such that \( 0 < |c| \ll 1 \) and \( Z^o \cap g_1^{-1}(c) \neq \emptyset \), where \( Z^o \) is a smooth Zariski-open of \( Z \) on which we have a shifted local system.

The above argument is, however, insufficient to prove the assertion that the cohomological direct images \( H^{1}\tilde{f}_* M \) are Hodge modules. (The last argument on the induced polarization is valid only after showing the latter assertion.) To show it, we have to take any point \( p' \in f(X) \) together with holomorphic functions \( g'_i \ (i \in [1, r]) \) satisfying (1.1.1)2 (with \( p \) replaced by \( p' \)) after replacing \( Y \) with a neighborhood of \( p' \) and taking an embedded resolution, which is given by a projective morphism \( \pi : \tilde{X} \to X \). (Here we do not have to assume (1.1.2) for \( p' \).) For the last morphism, we have the compatibility of decompositions for filtered \( D \)-modules and \( \mathbb{R} \)-complexes (see [Sa90b]) using Deligne’s canonical choice of decomposition depending on \( \ell \), see [De94]). So \( H^{1}\tilde{f}_* M \) is a direct factor of \( H^{1}\tilde{f}_* \tilde{M} \) with \( \tilde{f} := f \circ \pi \), where \( \tilde{M} \) is the level 0 Hodge module of normal crossing type on \( \tilde{X} \) whose restriction to \( \tilde{X} \setminus \pi^{-1}(D) \) coincides with the restriction of \( M \). Since the first two assertions are local on \( Y \), Theorem 1.1 then follows.

**Remark 1.1.** We used an argument similar to [Sa85] in [Sa90b].

### 1.2. Proof of Theorem 2

We show that Theorem 2 follows from Theorem 1.1 without relying on Theorem 1. Except the splitting of \( d_1 \), the assertions of Theorem 2 are local on \( Y \), and follow from Theorem 1.1. Here we need the hard Lefschetz property for the action of a relative Kähler class in order to get a global splitting of \( d_1 \) (using the associated global polarization of variation of Hodge structure).

The latter hard Lefschetz property is, however, needed only for the direct factor of the cohomological direct images with strict support \( f(X) \) in the notation of Theorem 1.1. Indeed, the higher direct images \( R^j f_* \omega D[D^{[k,l]}]/Y \) are uniquely determined by their restrictions to a dense Zariski-open subset of \( f(D[D^{[k,l]}]) \) over which \( f|D[D^{[k,l]}] \) is smooth (using the filtration \( V \) of Kashiwara and Malgrange, see [Sa88] (3.2.2.2)). This is proved in [Sa91] as a refinement of Kollár’s torsion-freeness theorem [Ko86].

The hard Lefschetz property for general fibers of \( f|D[D^{[k,l]}] : D[D^{[k,l]}] \to f(D[D^{[k,l]}]) \) follows from the classical Hodge theory on compact smooth Kähler general fibers. The weight spectral sequence (2) can be deduced from the corresponding one for Hodge modules (by restricting to \( F_0 \) and taking the tensor product with \( \omega_X \), see [FFS14]), where the differential \( d_1 \) preserves the strict supports. So Theorem 2 follows.

**Remark 1.2.** We say that a proper morphism of complex manifolds \( f : X \to Y \) is Kähler, if there is a relative Kähler form \( \xi_f \) (which is a closed real 2-form on \( X \)) such that locally on \( Y \) there is a Kähler form \( \xi_Y \) such that \( \xi_f + f^* \xi_Y \) is a Kähler form on \( X \). (Here “locally on \( Y \)” can be replaced with “locally on \( X \)” as in [Ta95, Def. 6.1], [Ya89] using semi-positivity of pullbacks of Kähler forms on \( Y \) since \( f \) is proper.) This definition seems apparently different from the one in [Ek78, Def. 4.1]. (Recall that a \( C^\infty \) function \( \phi \) on a complex manifold is strictly plurisubharmonic if and only if \( i\partial \bar{\partial} \phi \) is Kähler, see for instance [Ek78, Rem.1.1].) There is a problem if one wants to extend the above definition to the \( X \) singular case, since the cohomology class of \( \xi_f \) is not easy to define.
2. Hard Lefschetz property

In this section we prove the hard Lefschetz property after reviewing some basics of Gysin and restriction morphisms associated to blow-ups of complex manifolds along smooth centers.

2.1. Gysin and restriction morphisms. Let $\pi : \tilde{X} \to X$ be the blow-up of a complex manifold $X$ along a closed submanifold $Z \subset X$ with codimension $d$. Set $\tilde{Z} := \pi^{-1}(Z)$ with $i_{\tilde{Z}} : \tilde{Z} \to \tilde{X}$ the inclusion. This is a $\mathbb{P}^{d-1}$-bundle over $Z$. We have the restriction and Gysin morphisms

$$\rho : \mathbb{Q}_{\tilde{X}} \to \mathbb{Q}_{\tilde{Z}}, \quad \gamma : \mathbb{Q}_{\tilde{Z}} \to \mathbb{Q}_{\tilde{X}}(1)[2] \quad \text{in} \ D_c^b(\tilde{X}, \mathbb{Q}),$$

where the direct image by the closed immersion $i_{\tilde{Z}}$ is omitted to simplify the notation. Set $n := \dim X$, $m := \dim Z$.

These morphisms can be embedded into the distinguished triangles

$$\begin{align*}
(j_{\tilde{U}})_! \mathbb{Q}_{\tilde{U}} & \to \mathbb{Q}_{\tilde{X}} \xrightarrow{\rho} \mathbb{Q}_{\tilde{Z}}(1), \\
n-1[-2] & \to \mathbb{Q}_{\tilde{X}} \xrightarrow{\gamma} \mathbb{Q}_{\tilde{Z}} \to R(j_{\tilde{U}})_! \mathbb{Q}_{\tilde{U}},
\end{align*}$$

which are dual of each other, where $\tilde{U} := \tilde{X} \setminus \tilde{Z} (= X \setminus Z)$ with $j_{\tilde{U}} : \tilde{U} \to \tilde{X}$ the inclusion.

It is easy to verify that the compositions $\gamma \circ \rho$ and $\rho \circ \gamma$ are respectively identified with the actions of the cohomology class of $\tilde{Z} \subset \tilde{X}$ and its restriction to $\tilde{Z}$, using the canonical isomorphisms

$$H^2(\tilde{X}, \mathbb{Q})(1) = \text{Hom}(\mathbb{Q}_{\tilde{X}}, \mathbb{Q}_{\tilde{X}}(1)[2]) \quad \text{(and similarly for $\tilde{Z}$).}$$

By the decomposition theorem for projective morphisms [Sa88], we have the isomorphisms

$$\begin{align*}
R\pi_* \mathbb{Q}_{\tilde{X}}[n] & \cong \mathbb{Q}_X[n] \oplus \bigoplus_{i=0}^{d-2} (\mathbb{Q}_Z[m])(-i-1)[d-2-2i], \\
R\pi_* \mathbb{Q}_{\tilde{Z}}[n-1] & \cong \bigoplus_{i=0}^{d-1} (\mathbb{Q}_Z[m])(-i)[d-1-2i].
\end{align*}$$

Here we can take Deligne’s canonical choice of decomposition using the relative ample divisor $-\tilde{Z}$, see [De94]. (It is not clear whether these direct sum decompositions are compatible with the Gysin and restriction morphisms.) Fixing the decomposition, we can define the decreasing filtration $G^*$ on $R\pi_* \mathbb{Q}_{\tilde{Z}}[n-1]$ so that

$$G^k R\pi_* \mathbb{Q}_{\tilde{Z}}[n-1] \cong \bigoplus_{i=k}^{d-1} (\mathbb{Q}_Z[m])(-i)[d-1-2i].$$

This is opposite to a well-defined filtration $G'_k$ ($k \in \mathbb{Z}$) defined by the truncations $\tau_{\leq n+2k}$ (or $p_{\leq n+2k}$, see [BBD82]). The first decomposition of $\mathbb{Q}_{\tilde{X}}[n]$ can be induced by the restriction morphism for $\tilde{X} \to X$ and the Gysin morphism for $\tilde{Z} \hookrightarrow \tilde{X}$:

$$\begin{align*}
\mathbb{Q}_X[n] & \to R\pi_* \mathbb{Q}_{\tilde{X}}[n], \\
\mathbb{Q}_{\tilde{Z}}[-2] & \to R\pi_* R\Gamma_{\tilde{Z}} \mathbb{Q}_{\tilde{X}}[n] \to R\pi_* \mathbb{Q}_{\tilde{X}}[n].
\end{align*}$$

2.2. Proof of the hard Lefschetz property. Let $f : X \to Y$ be a proper Kähler morphism. Set $\mathcal{M}_X := ((\mathcal{O}_X, \mathcal{F}), \mathbb{R}_X[n])$, and similarly for $\mathcal{M}_{\tilde{X}}$, etc. Put $f_Z := f|_Z$, $\tilde{f}_Z := \tilde{f}|_{\tilde{Z}}$ with the notation of 2.1. By Theorem 1.1 the cohomological direct images

$$\mathcal{H}^j f_* \mathcal{M}_X, \quad \mathcal{H}^j \tilde{f}_* \mathcal{M}_{\tilde{X}}, \quad \mathcal{H}^i(f_Z)_* \mathcal{M}_Z, \quad \mathcal{H}^i(\tilde{f}_Z)_* \mathcal{M}_{\tilde{Z}}$$

are locally polarizable Hodge modules on $Y$ of weight $n+j$, $n+j$, $m+j$, $n-2+j$ respectively. Using [De94] as is explained in [Sa90b], we can get the isomorphisms

$$\begin{align*}
\mathcal{H}^j f_* \mathcal{M}_X & \cong \mathcal{H}^j f_* \mathcal{M}_X \oplus \bigoplus_{i=0}^{d-2} \mathcal{H}^{j+d-2-2i}(f_Z)_* \mathcal{M}_Z(-i-1), \\
\mathcal{H}^j(\tilde{f}_Z)_* \mathcal{M}_{\tilde{Z}} & \cong \bigoplus_{i=0}^{d-1} \mathcal{H}^{j+d-1-2i}(f_Z)_* \mathcal{M}_Z(-i).
\end{align*}$$

These are compatible with the direct image of the decompositions (2.1.3) (using [De94]).
Let \( \ell \) be the pull-back to \( \tilde{X} \) of a relative Kähler class \( \ell_X \) for \( f \). Let \( \ell' \) be the cohomology class of the relatively ample divisor \(-\tilde{Z}\) for \( \pi \). It is known that \( \ell_c := \ell + c \ell' \) \((0 < c \ll 1)\) is a relative Kähler class for \( \tilde{f} \).

For the proof of the hard Lefschetz property (1) and the induced polarization on the primitive part, it is enough to show the following.

**Theorem 2.2.** Assume the hard Lefschetz property (1) and the induced polarization on the primitive part hold for \( \tilde{f}, \ell_c \) \((0 < c \ll 1)\) and also for \( f_Z, \ell_Z \), where \( f_Z := f|_Z, \ell_Z := \ell_X|_Z \).

Then they hold for \( f \) and \( \ell_X \).

**Proof.** Set \( \mathcal{M}^{(j)}_= = \mathcal{H}^{-j}\ell_*\mathcal{M}_X = (-j) \), and similarly for \( \mathcal{M}^{(j)}_Z \), etc. Then (2.2.3) gives the isomorphisms

\[
\mathcal{M}^{(j)}_X \cong \mathcal{M}^{(j)}_X + \bigoplus_{i=0}^{d-2} M^Z\left(j-d+2+2i\right)(i-d+1),
\]

\[
\mathcal{M}^{(j)}_Z \cong \bigoplus_{i=0}^{d-1} M^Z\left(j-d+1+2i\right)(i-d+1).
\]

Put \( \mathcal{M}^{(\ast)}_X := \bigoplus_{j \in \mathbb{Z}} \mathcal{M}^{(j)}_X \), etc. We have the actions

\[
\ell, \ell' : \mathcal{M}^{(\ast)}_X \to \mathcal{M}^{(\ast)}_X(-1)[-2],
\]

and similarly for \( \mathcal{M}^{(\ast)}_Z \). Let \( L \) be the monodromy filtration for the action of \( \ell \) on \( \mathcal{M}^{(\ast)}_X, \mathcal{M}^{(\ast)}_Z \).

(This commutes with \( \gamma, \rho \), since this is the action of a cohomology class of \( \tilde{X} \).) By [CKS 82, CKS 86], we can apply [Sa 88, Lem. 5.2.15] to fibers of generic variations of Hodge structure for each strict support of \( \mathcal{M}^{(\ast)}_X, \mathcal{M}^{(\ast)}_Z \) (using the \( \ell \)-primitive decomposition). This implies the decomposition

\[
\text{Gr}^L\mathcal{M}^{(\ast)}_X = \text{Ker} \text{Gr}^L\rho \oplus \text{Im} \text{Gr}^L\gamma,
\]

where

\[
\text{Im} \text{Gr}^L\rho = \text{Gr}^L G^1 \mathcal{M}^{(\ast)}_X, \quad \text{Ker} \text{Gr}^L\gamma = \text{Gr}^L G^{d-1} \mathcal{M}^{(\ast)}_X,
\]

with \( G \) as in (2.1.4). Note that these never hold without taking \( \text{Gr}^L \). Here it is not easy to verify the sign. If the sign is wrong, the lemma would imply a decomposition of \( \text{Gr}^L \mathcal{M}^{(\ast)}_X \) instead of \( \text{Gr}^\ell \mathcal{M}^{(\ast)}_X \). However, one can easily see that this is not possible in this simple case using the decompositions (2.2.3) together with (2.2.7) below, see also Remark 2.2 below.

By hypothesis, the hard Lefschetz property holds for \( f_Z, \ell_Z \). So the filtration \( L \) on \( \mathcal{M}^{(\ast)}_Z \) is induced via the isomorphism (2.2.4) by the filtration \( L \) on \( \mathcal{M}^{(\ast)}_X \) such that

\[
L_k \mathcal{M}^{(\ast)}_Z = \bigoplus_{j \leq m+k} \mathcal{M}^{(j)}_Z,
\]

since \( \ell \) comes from \( \ell_X \). It is then easy to verify that the action of \( \ell' \) on \( \text{Gr}^L_k \mathcal{M}^{(\ast)}_Z \) is essentially given by the identity (or zero) via the isomorphism (2.2.4) as is expected.

Since \( \ell \) is the pullback of \( \ell_X \), its action is compatible with the decomposition in (2.2.4), and we can apply a similar argument to the second direct factor. We then see that \( \text{Im} \text{Gr}^L\gamma \) coincides with the second direct factor using the decomposition (2.2.5). Indeed, \( \text{Im} \text{Gr}^L\gamma \) contains the second direct factor by an argument around (2.1.5), and \( \text{Im} \text{Gr}^L\gamma \) is injectively sent to \( \mathcal{M}^{(\ast)}_Z \) by \( \text{Gr}^L \rho \) as a consequence of (2.2.5) (and \( \rho \circ \gamma \) coincides with the action of \( \ell' \) up to a sign). We then get the isomorphism as bi-graded Hodge modules

\[
\text{Gr}^L_\ast \mathcal{M}^{(\ast)}_X \cong \text{Ker} \text{Gr}^L_\ast \rho \subset \text{Gr}^L_\ast \mathcal{M}^{(\ast)}_X.
\]

For the proof of the hard Lefschetz property for \( f, \ell_X \), it is enough to show

\[
\text{Gr}^L_k \mathcal{M}^{(j)}_X = 0 \quad (k \neq j+n).
\]
By [CK82], [CKS86] together with the hypothesis, the relative monodromy filtration for \( \ell', L \) coincides with the monodromy filtration for \( \ell_c := \ell + c\ell' \) \((0 < c \ll 1)\), and the hard Lefschetz property holds for this so that the monodromy filtration for \( \ell_c \) coincides with the filtration by degree up to shift. By definition, the relative monodromy filtration induces the monodromy filtration for \( \text{Gr}_k^L\ell' \) shifted by \( k \) on each \( \text{Gr}_k^L\mathcal{M}_X^{(q)} \). It is easy to see that the action of \( \text{Gr}_k^L\ell' \) on \( \text{Gr}_k^L\mathcal{M}_X^{(q)} \) is compatible with the direct sum decomposition (2.2.5), since \( \gamma \circ \rho = \pm \ell' \). The action of \( \text{Gr}_k^L\ell' \) vanishes on the direct factor \( \text{Ker} \text{Gr}_k^L\rho \), hence the relative monodromy filtration (or the monodromy filtration for \( \ell_c \)) induces a trivial filtration on each \( \text{Ker} \text{Gr}_k^L\rho \). So the condition (2.2.9) is satisfied for \( \text{Ker} \text{Gr}^L_k\rho \), and it holds for \( \text{Gr}_k^L\mathcal{M}_X^{(q)} \) using the bi-graded isomorphism (2.2.8).

It remains to show the assertion on the induced polarization on the \( \ell' \)-primitive part. For this we can apply a well-known assertion saying that a continuous family of non-degenerate hermitian matrices parametrized by a connected interval in \( \mathbb{R} \) is everywhere positive-definite if so is at one point. This finishes the proof of Theorem 2.2.

**Remark 2.2a.** Originally it was not thought that [Sa 88, Lem. 5.2.15] was very useful, since the decomposition (2.2.5) never holds without taking \( \text{Gr}_k^L \). It turns out, however, that the decomposition of \( \text{Gr}_k^L \) is enough for the proof, studying carefully the property of relative monodromy filtration.

**Remark 2.2b.** A similar argument in a more general situation seems to be employed in twistor theory. There is, however, a sign problem in order to apply [Sa 88, Lem. 5.2.15] to the higher level case. For instance, assume there is a variation of Hodge structure of level 1, weight 1, and rank 2 defined outside a divisor \( D \) with simple normal crossings on a surface \( X \) and having non-semisimple unipotent local monodromies along the irreducible components of \( D \). Let \( \mathcal{M} \) be the Hodge module of weight 3 with strict support \( X \) extending the variation of Hodge structure. Set \( U := X \setminus D \) with \( j_U : U \hookrightarrow X \) the inclusion. Then \( \mathcal{M}' := \text{Gr}_k^W(j_U)_*j_U^!\mathcal{M} \) is supported at the singular points of \( D \), and is 1-dimensional at each point (using a combinatorial description of regular holonomic \( \mathcal{D} \)-module of normal crossing type, see for instance [Sa 90a, Sa 22]). In this case, we see that [Sa 88, Lem. 5.2.15] cannot give a decomposition of the direct image of \( \mathcal{M} \), since the action of \( \ell' (= \pm \rho \circ \gamma) \) on \( \mathcal{M}' \) vanishes so that \( \text{Im Gr}_k^L\gamma \subset \text{Ker Gr}_k^L\rho \). It must give instead a (trivial) decomposition of (the direct image of) \( \mathcal{M}' \), see also [Sa 17, Rem. (iii) in 2.6].

**Example 2.2.** Let \( \rho : X \to C \) be an elliptic surface over a smooth compact curve \( C \). Let \( \mathcal{M}_C \) be the pure Hodge module of weight 2 with strict support \( C \) whose restriction to a Zariski-open \( C^o \subset C \) is the variation of Hodge structure of level 1 and weight 1 associated to \( \rho \) (up to shift of complex). Assume \( \mathcal{M}_C \) has a non-semisimple unipotent monodromy at \( q \in C \), and \( D := \rho^{-1}(p) \) is a divisor with simple normal crossings. Let \( \mathcal{M} \) be the pure Hodge module of weight 3 with strict support \( X \) whose restriction to \( \rho^{-1}(C^o) \) is the pullback of \( \mathcal{M}_C|_{C^o} \) (shrinking \( C^o \)).

Let \( \ell'' \) be the cohomology class of \( D \) (with multiplicity). The construction of the action of \( \ell'' \) via the Gysin and restriction morphisms as in Remark 2.21 seems to be compatible with the direct image (using duality), and the direct image of the action seems to coincide with the action of the cohomology class \( \ell_q \) of \( q \) on the direct image. Here we have essentially the self-product of \( X \) over \( C \), and the middle direct image \( H^0\rho_*\mathcal{M} \) has a trivial direct factor \( \mathbb{Q}_h.c.(-1)[1] \) (corresponding to the polarization). In case the restriction to it of the direct image of the action of \( \ell'' \) coincides with the action of \( \ell_q \), it does not vanish (since it can be used as a definition of cycle map, see for instance [Sa 89, 1.15]). In this case it would further imply the non-vanishing of the action of the cohomology class of some irreducible component \( D_i \) (which is usually contractible at least analytically).
