Abstract

The goal of information-seeking dialogue is to respond to seeker queries with natural language utterances that are grounded on knowledge sources. However, dialogue systems often produce unsupported utterances, a phenomenon known as hallucination. Dziri et al. (2022)’s investigation of hallucinations has revealed that existing knowledge-grounded benchmarks are contaminated with hallucinated responses at an alarming level (>60% of the responses) and models trained on this data amplify hallucinations even further (>80% of the responses). To mitigate this behavior, we adopt a data-centric solution and create FAITHDIAL, a new benchmark for hallucination-free dialogues, by editing hallucinated responses in the Wizard of Wikipedia (WoW) benchmark. We observe that FAITHDIAL is more faithful than WoW while also maintaining engaging conversations. We show that FAITHDIAL can serve as training signal for: i) a hallucination critic, which discriminates whether an utterance is faithful or not, and boosts the performance by 21.1 F1 score on the BEGIN benchmark compared to existing datasets for dialogue coherence; ii) high-quality dialogue generation. We benchmark a series of state-of-the-art models and propose an auxiliary contrastive objective that achieves the highest level of faithfulness and abstractiveness based on several automated metrics. Further, we find that the benefits of FAITHDIAL generalize to zero-shot transfer on other datasets, such as CMU-DOG and TOPICALCHAT. Finally, human evaluation reveals that responses generated by models trained on FAITHDIAL are perceived as more interpretable, cooperative, and engaging.

1 Introduction

Despite the recent success of knowledge-grounded neural conversational models (Thoppilan et al., 2022; Prabhumoye et al., 2021; Zhao et al., 2020, inter alia) in generating fluent responses, they also generate unverifiable or factually incorrect statements, a phenomenon known as hallucinations (Rashkin et al., 2021b; Dziri et al., 2021a; Shuster et al., 2021). Ensuring that models are trustworthy is key to deploying them safely in real-world applications, especially in high-stake domains. In fact, they can unintentionally inflict harm on members of the society with unfounded statements or can be exploited by malicious groups to spread large-scale disinformation.

Recently, Dziri et al. (2022) investigated the underlying roots of this phenomenon and found that the gold-standard conversational datasets (Dinan et al., 2018; Gopalakrishnan et al., 2019; Zhou et al., 2018)—upon which the models are commonly fine-tuned—are rife with hallucinations, in more than 60% of the turns. For instance, in Wizard of Wikipedia (WoW; Dinan et al. 2018), an information SEEKER aims to learn about a topic and a human WIZARD harnesses knowledge (typically a sentence) from Wikipedia to answer. An example of hallucination in WoW is shown in the
red box of Figure 1. This behavior, where the human WIZARD ignores the knowledge snippet and assumes a fictitious persona, can later reverberate in the dialogue system trained on this kind of data. Instead, the ideal WIZARD response, highlighted in green, should acknowledge the bot’s nature, and whenever the knowledge is not sufficient or relevant, it should acknowledge its ignorance of the topic.

Unfortunately, modeling solutions alone cannot remedy the hallucination problem. By mimicking the distributional properties of the data, models are bound to ‘parrot’ the hallucinated signals at test time (Bender et al., 2021). What is more, Dziri et al. (2022) observe that GPT2 not only replicates, but even amplifies hallucination around 20% when trained on WoW. This finding also extends to models that are designed explicitly to be knowledge-grounded (Prabhumoye et al., 2021; Rashkin et al., 2021b). Filtering noisy or high-error data (Zhang and Hashimoto, 2021) is also prone to failure as it may either break the cohesion of discourse or it may require excluding entire dialogues.

In this work, we adopt instead a data-centric solution to address hallucinations and create FAITHDIAL, a new benchmark for faithful knowledge-grounded dialogue. Specifically, we ask annotators to amend hallucinated utterances in WoW by making them faithful to the corresponding knowledge snippets from Wikipedia and acknowledging ignorance when necessary. This approach is vastly more scalable than creating FAITHDIAL from scratch while retaining the cohesiveness of conversations. Moreover, it allows us to shed light on hallucinations by contrasting corresponding WIZARD’s responses in WoW and FAITHDIAL.

As a result, FAITHDIAL contains around 50K turns across 5.5K conversations. Extensive human validation reveals that 94.4% of the utterances in FAITHDIAL are faithful (i.e., without hallucinations), compared to only 20.9% in WoW. Moreover, we benchmark several state-of-the-art models (Radford et al., 2019; Roller et al., 2021; Raffel et al., 2020; Rashkin et al., 2021b) on dialogue generation. If trained on FAITHDIAL, we find that they are significantly more faithful while also enhancing other dialogue aspects like cooperativeness, creativity or engagement. These benefits also generalize to other knowledge-grounded datasets like CMU-DoG (Zhou et al., 2018) and TopicalChat (Gopalakrishnan et al., 2019) in a zero-shot transfer setting.

FAITHDIAL also provides supervision for hallucination critics, which discriminate whether an utterance is faithful or not. We source positive examples from FAITHDIAL and negative examples from WoW and data augmentation. Compared to other dialogue inference datasets (Welleck et al., 2019; Nie et al., 2021), the classifiers trained on this data (which we call FAITHCritic) generalize better to general NLU tasks like MNLI (Williams et al., 2018) and achieve state-of-the-art on hallucination detection proper in BEGIN (Dziri et al., 2021b) in a zero-shot setting.

Thus, FAITHDIAL holds promise to encourage faithfulness in information-seeking dialogue and make virtual assistants both safer and more reliable. We release data and code for future research.\footnote{https://mcgill-nlp.github.io/FaithDial/}

2 FAITHDIAL: Dataset Design

Given the motivations adduced above, the primary goal of this work is to create a resource for faithful knowledge-grounded dialogue that allows for both training high-quality models and measuring the degree of hallucination of their responses.

We define the notion of faithfulness (i.e., lack of hallucination) formally as follows:

**Definition 2.1** (Faithfulness). Given an utterance \( u_n \), a dialogue history \( H = (u_1, \ldots, u_{n-1}) \), and knowledge \( K = (k_1, \ldots, k_j) \) at turn \( n \), we say that \( u_n \) is trustworthy with respect to \( K \) iff the following condition holds:

\[
\exists \Gamma_n \text{ such that } \Gamma_n \vDash u_n, \text{ where } \vDash \text{ denotes semantic consequence and } \Gamma_n \text{ is a non-empty subset of } K_n. \text{ In other words, there is no interpretation } \mathcal{I} \text{ such that all members of } \Gamma_n \text{ are true and } u_n \text{ is false.}
\]

Hence, an utterance can optionally be grounded on multiple facts but not none.

In what follows, we present the design of our task as well as our annotation pipeline to curate FAITHDIAL. In our dialogue setting, we simulate interactions between two speakers: an information SEEKER and a bot WIZARD.

**Definition 2.2** (Information Seeker: A Human). The information SEEKER, a human, aims at learning about a specific topic in a conversational manner. They can express subjective information, bring up a new set of facts independent from the source \( K \), and even open up new sub-topics.
From the perspective of Definition 2.2, utterances pronounced by the SEEKER have a large degree of freedom. For example, the human can chat about personal life and can ask a diverse set of questions. On the other hand, the WIZARD is more restricted on what they can communicate.

**Definition 2.3 (WIZARD: A Bot).** The WIZARD, a bot, aims at conversing in a knowledgeable manner about the SEEKER’s unique interests, resorting exclusively to the available knowledge $K$. They can reply to a direct question or provide information about the general topic of the conversation.

From Definition 2.3, it follows that there are three key rules the bot must abide by: first, it should be truthful by providing information that is attributable to the source $K$. Second, it should provide information conversationally, i.e., use naturalistic phrasing of $K$, support follow-on discussion with questions, and prompt user’s opinions. Third, it should acknowledge its ignorance of the answer in those cases where $K$ does not include it while still moving the conversation forward using $K$.

### 2.1 Data Selection

Rather than creating a novel benchmark from scratch, however, we opt for fixing problematic utterances (which are the majority) in existing ones (Table 1). The reason is three-fold: 1) while mostly hallucinated, existing datasets still contain useful faithful information. 2) as correction is faster than creation from scratch, this enables us to annotate examples on a larger scale; 3) two versions of the same dialogue turn, either hallucinated or faithful, can provide signal for (contrastive) learning and evidence for a linguistic analysis. In particular, we focus on WoW as our benchmark backbone.

Initial pilot study revealed that WoW dialogues are more suitable for editing compared to other prominent knowledge-grounded dialogue benchmarks: TopicalChat (Gopalakrishnan et al., 2019) and CMU-DoG (Zhou et al., 2018). In fact, ac-

Table 1: The breakdown of responses from WoW, CMU-DoG and TopicalChat according to Dziri et al. (2022). “Faith.” refers to faithful responses and “Uncoop.” refers to faithful but uncooperative responses given the conversation history.

Our first step consists in filtering out WoW conversations where ground-truth knowledge $K$ was not given, and annotators relied on personal knowledge instead. Then, we focus on SEEKER-initiated conversations and sample 44% from the train (4094 conversations) and 100% from validation (764 conversations) and 100% from test (791 conversations).

### 2.2 Crowd-sourced Annotations

Following the guidelines for ethical crowdsourcing outlined in Sheehan (2018), we hire Amazon Mechanical Turk (AMT) workers to edit utterances in WoW dialogues that were found to exhibit unfaithful responses. First, workers were shown dialogues from WoW and asked to determine whether the WIZARD utterances are faithful to the source knowledge. To guide them in this decision, they were additionally requested to identify the speech acts (VRM taxonomy; Stiles 1992) such as disclosure, edification, question, acknowledgment, etc; and the response attribution classes (BEGIN taxonomy; Dziri et al. 2021b) such as hallucination and entailment for each of the WIZARD’s utterances according to Dziri et al. (2022)’s schema.

2.2.1 Editing the Wizard’s Utterances

Workers were instructed to edit the WIZARD’s utterances in the following cases, depending on their faithfulness and speech act.

**Hallucination.** They should remove information that is unsupported by the given knowledge snippet \( \mathcal{K} \), and replace it with information that is supported. To ensure that the responses are creative, we disallowed workers from copying segments from \( \mathcal{K} \). They were instead instructed to paraphrase the source knowledge as much as possible without changing its meaning (Ladhak et al., 2021; Lux et al., 2020; Goyal and Durrett, 2021). If the inquiry of the SEEKER cannot be satisfied by the knowledge \( \mathcal{K} \), the WIZARD should acknowledge their ignorance and carry on the conversation by presenting the given knowledge in an engaging manner. In the example shown in Table 4, the new WIZARD confirms that it cannot surf and instead enriches the conversation by talking about surfing as opposed to the original WIZARD who hallucinates personal information.

**Generic** utterances such as “That’s nice” should be avoided solely on their own. Workers are instructed to enrich these responses with content that is grounded on the knowledge.

**Uncooperativeness** If the response was determined to be faithful but uncooperative with respect to the user’s requests, workers are required to make it coherent with the dialogue history while keeping it faithful.

2.2.2 Editing the Seeker’s Utterances

Although the SEEKER has no restrictions on their utterances, it is inevitable that the conversation may drift away—because of the edits on the WIZARD’s response—making the existing SEEKER’s next utterance in WoW incoherent with the new context. In these cases, workers re-revise the WIZARD’s response until it fits between the SEEKER’s previous and next utterance. When this is infeasible, they perform minimal edits on the SEEKER’s next utterance to make it coherent (see Table 3 for editing statistics). Consider Table 4 where workers had to edit the original SEEKER’s utterance as it was not coherent anymore with the freshly edited WIZARD’s response.

### Table 4: A FAITHDIAL dialogue example.

**SEEKER:** I would love to learn to surf but I’m terrified of sharks! Do you surf?

**Knowledge:** Surfing is a surface water sport in which the wave rider, referred to as a surfer, rides on the forward or deep face of a moving wave, which is usually carrying the surfer towards the shore.

**WOW WIZARD:** I absolutely love to surf, just riding on the forward face of a moving wave is so exhilarating. Are there a lot of sharks near you?

**FAITHDIAL WIZARD:** Unfortunately, it’s impossible for me to surf. Remember, I’m just your virtual bot! Sorry to hear you’re terrified from sharks. However, did you know that a surfer is someone who can ride on either the forward or deep face of a wave which typically sends her/him close to the shore? 😊

**WOW SEEKER:** I have no idea how many sharks are in the Gulf of Mexico but there out there! lol Where do you like to surf?

**FAITHDIAL SEEKER:** Yeah, what scares me is the sharks, is there any non-ocean waves out there? 😊

3 Dataset Analysis

3.1 Human validation

To evaluate the quality of the FAITHDIAL data, we run two final rounds of annotations. Firstly, we ask 3 workers to edit the same 500 responses. Since there is no straightforward way to measure inter-annotator agreement on edits, following Dziri et al. (2022), we measure the inter-annotator agreement on the response attribution classes (BEGIN) and the speech acts (VRM). We report an inter-annotator agreement of 0.75 and 0.61 Fleiss’ \( \kappa \), respectively, which shows substantial agreement according to Landis and Koch (1977). This is an indicator of overall annotation quality: if the worker can reliably identify speech acts, they generally also produce reasonable edits. Secondly, we assign three new workers to annotate the same 500 edited responses and ask them to judge their faith-
fulness (we use majority vote): 94.4% of the edited responses were found to be grounded on $\mathcal{K}$ while 5.6% are partially hallucinated. Assuming the pre-existing labels to be correct, the F1 score of the majority-vote annotations for both taxonomies are similarly high: 90% for BEGIN and 81% for fine-grained VRM.

### 3.2 Dataset Statistics

Overall, FAITHDIAL contains a total of 5,649 dialogues consisting of 50,761 utterances. Table 2 reports statistics for each dataset split. To curate FAITHDIAL, workers edited 84.7% of the WIZARD responses (21,447 utterances) and 28.1% of the SEEKER responses (7,172 utterances). In particular, 3.8 WIZARD turns per conversation were modified on average, as opposed to only 1.2 SEEKER turns. The low percentage of the SEEKER edits shows that our method does not disrupt the cohesiveness of the conversations.

### 3.3 Linguistic Phenomena

#### 3.3.1 Faithfulness

Based on our human validation round of 500 examples, FAITHDIAL contains 94.4% faithful responses and 5.6% hallucinated responses, as shown in Figure 2 (inner circle). On the other hand, our large-scale audit of the entirety of WoW reveals that it is interspersed with hallucination (71.4%), with only a few faithful turns (20.9%). This finding is consistent with the analysis of Dziri et al. (2022) on a smaller sample. In our work, FAITHDIAL cleanses dialogues from hallucination almost entirely.

We also report the speech acts employed to ensure faithfulness in FAITHDIAL in the outer circle in Figure 2. We observe that WIZARD resorts to a diverse set of speech acts to convey faithful information in a conversational style (see the Entailment pie): 78.26% of the responses contain objective content (Edification) that is interleaved with dialogue acts such as acknowledging receipt of previous utterance (18.3%), asking follow-up questions (35.5%), and sparking follow-up discussions by expressing opinions still attributable to the knowledge source (36.2%). Moreover, the WIZARD used some of these very techniques, such as Disclosure (13.04%) and Questions (8.6%), in isolation. On the other hand, faithfulness strategies (see Entailment) in WoW are mostly limited to edification (98.9%), curbing the naturalness of responses.

#### 3.3.2 Abstractiveness

After establishing the faithfulness of FAITHDIAL, we investigate whether it stems from an increased level of extractiveness or abstractiveness with respect to the knowledge source. Extractive responses reuse the same phrases as the knowledge source, while abstractive responses express the same meaning with different means. Although extractive responses are an easy shortcut to achieving more faithfulness, it comes at the cost of creativity. Ideally, we want responses that are faithful as well as creative. To measure creativity, we borrow two metrics from Grusky et al. (2018) designed to quantify the extractive and abstractive nature of summaries: Density and Coverage. Density represents the average length of the text spans copied from the knowledge that are contained in the response. Coverage instead measures the percentage of words existing in a response that are also found in the source knowledge. Figure 3 illustrates the density and coverage distributions in FAITHDIAL (right) vs. WoW (left). We observe that while the coverage (x-axis) is similar in both FAITHDIAL and WoW, the density (y-axis) is always low in FAITHDIAL but often high in WoW. This indicates that responses in FAITHDIAL tend to be abstractive to a large degree.

Based on this, we also study which specific abstractive strategies WIZARD adopts to present knowledge from $\mathcal{K}$ without repeating long fragments. The strategies we discovered, illustrated in Table 10, fall into five broad categories: inference of new knowledge from $\mathcal{K}$, rewording, reshaping the syntactic structure, abridging long expressions, and introducing connectives. We discuss these categories in more detail in §D.

#### 3.3.3 Fallback Responses in FAITHDIAL

We further probe the WIZARD responses with respect to their ability to handle unanswerable questions. We randomly sample 45 dialogues containing 200 WIZARD responses and ask a linguist to annotate them. Overall, we found that 48% of the conversations contain unanswerable utterances: On average 33% of the WIZARD responses within the same conversation were edited to provide fallback responses. Out of those fallback responses, 30% were triggered by personal questions, 50% by objective questions about the topic, and 20% by opinions. In these cases, to avoid interrupting the flow of the conversation, the WIZARD informs the SEEKER about facts from the source knowledge.
Figure 2: Coarse-grained (BEGIN) and fine-grained speech act (VRM) distributions used by wizards in **FAITHDIAL** and WoW. The inner most circle shows the breakdown of coarse-grained types: Hallucination (red), Entailment (green), Partial Hallucination (yellow), Generic (purple), and Uncooperative (pink). The outer circles show the fine-grained types of each coarse-grained type.

besides acknowledging its ignorance of the right answer.

4 Experiments

The purpose of **FAITHDIAL** is two-fold. The first goal is providing high-quality data to generate faithful responses in information-seeking dialogue. Given knowledge $K_n$ and the conversation history $H = (u_1, \ldots, u_{n-1})$, the task is to generate a response $u_n$ faithful to $K_n$. The second goal is to use the collected labels as training data for a critic to determine whether a given response is faithful or hallucinated. We benchmark a series of state-of-the-art dialogue models (Radford et al., 2019; Roller et al., 2021; Raffel et al., 2020; Rashkin et al., 2021b) on **FAITHDIAL**. We also evaluate them on WoW and in a zero-shot transfer setup on CMU-DoG, and TopicalChat). Further, we evaluate the critic model on MNLI (Williams et al., 2018), a generic language understanding task, as well as on BEGIN, a knowledge-grounded evaluation benchmark for hallucinations, both in zero-shot setting.

4.1 Task I: Hallucination Critic

We frame the problem of identifying hallucination as a binary classification task where the goal is to predict whether an utterance is faithful or not, given the source knowledge. This characterization of the problem is reminiscent of previous work (Dziri et al., 2019; Welleck et al., 2019b; Nie et al., 2021) on detecting contradiction within a conversation.

For this purpose, we curate a dataset, **FAITHCRITIC**, derived from human annotations in **FAITHDIAL**. Specifically, we take 14k Wizard utterances from WoW labelled as hallucination (Section 2) as negative examples. The Wizard responses from WoW labelled as entailment along with newly edited WIZARD utterances (20k in total) count as positive examples. Overall, **FAITHCRITIC** consists of 34k examples for training. We compare the performance of models trained on **FAITHCRITIC** against models trained on two dialogue inference datasets —DNLI (Welleck et al., 2019b) and DECODE (Nie et al., 2021)—and on a well-known natural language inference (NLI) dataset, MNLI (Williams et al., 2018). For all datasets, we choose RoBERTa$\text{Large}$ (Liu et al., 2019) as a pre-trained model. We measure the transfer performance of dif-

4.2.2 Automatic Evaluation

We rely on several metrics that provide a multi-
faceted measure of performance. A first group measures the degree of hallucination of generated
responses. The Critic model trained on FAITH-
CRITIC (Section 4.1) returns the percentage of ut-
erances identified as unfaithful. $Q^2$ (Honovich et al., 2021) measures faithfulness via question answering. It takes a candidate response as input and then generates a corresponding question. Then, it identifies possible spans in the knowledge source to justify the question–answer pair (Durmus et al., 2020; Wang et al., 2020). Finally, it compares the candidate response with the knowledge span, in terms of either token-level $F_1$ score or a NLI-inspired similarity score based on a RoBERTa model. BERTScore (Zhang et al., 2019) rates the semantic similarity between the generated response $r$ and the knowledge $K$ based on the cosine of their sentence embeddings. $F_1$ measures instead the token-level lexical overlap between $r$ and $K$. Finally, as a second set of metrics, we report BLEU (Papineni et al., 2002) and ROUGE (Lin, 2004), which reflect instead the n-gram overlap between $r$ and the gold (faithful) response $g$. WOW vs FAITHDIAL. In order to evaluate the ability of FAITHDIAL to reduce hallucination in generated responses, Table 6 illustrates three experimental setups with different training data. WOW
corresponds to the first block and FAITHDIAL to the second block. The third block reflects a hybrid setup where a model is fine-tuned sequentially on WoW as an intermediate task and then on FAITHDIAL. All models are tested on the FAITHDIAL test set.

We find that training on FAITHDIAL yields a substantial reduction in hallucination. For example, T5 trained on FAITHDIAL decreases hallucination by 42.2% according to the Critic and increases the faithfulness score (Q²-NLI) by 4.3% compared to T5 trained on WoW.5 This corroborates the prominence of data quality compared to the data quantity (FAITHDIAL is one third of WoW). When initializing the models trained on FAITHDIAL with the noisy checkpoint from WoW (third block), we observe a performance boost in all models across all metrics, except a marginal drop in Critic for GPT2 and DIALOGPT. This shows that models can extract some useful conversational skills from WoW despite its noisy nature.

5The relatively high score of T5-WoW on Q²-NLI can be explained by the fact that this metric may not be robust to partial hallucinations.

### Models

First, we observe that T5 consistently performs favourably in reducing hallucination in all setups and across all metrics, compared to the rest of the vanilla baselines: GPT2, DIALOGPT, and DoHA. Additionally, we compare models that are designed specifically to alleviate hallucination. Results are reported in the grey blocks of Table 6. We choose the best vanilla model T5 as the backbone for CTRL, INFOANCE and LOSSTRUNCATION. We observe that by virtue of these methods faithfulness increases even further, which demonstrates their effectiveness.

### Abstractiveness

We find that while FAITHDIAL, especially in the hybrid setup, increases the semantic similarity between generated responses and knowledge (BERTScore) by 16%, the word overlap (F1) between them is almost unaffected. This indicates that WoW induces extractiveness over abstractiveness in models, which is not desirable. This is especially true for T5-CTRL variants, as their training objective encourages word overlap. Instead, we observe that T5-INFOANCE achieves both faithfulness and abstractiveness as it yields the lowest scores for hallucination (1.4 Critic) and extractiveness (55.8 F1).

| Knowledge: Game Design is the art of applying design and aesthetics to create a game for entertainment or for educational, exercise, or experimental purposes. History: I design video games for a living. Do you play any video games? | T5-CTRL-WoW: I have always wanted to be an artist. I think it’s a fun hobby to learn about the art of applying design and aesthetics to create a game for entertainment or for educational purposes. (Partial Hallucination) T5-CTRL-FAITHDIAL: Given the fact that I’m a bot, I don’t play video games. However, I do know that applying design to make games is the art of making games for entertainment or educational purposes. (Faithful) |

### 4.2.3 Human Evaluation

In addition to the automated metrics, we conduct human evaluation to assess the presence of hallucination in models trained on FAITHDIAL, as well as other aspects in generated dialogues such as cooperativeness, engagingness, and abstractiveness. Following Rashkin et al. (2021a), our evaluation consists of a two-stage annotation process. First, the annotators are asked to determine whether responses are stand-alone (i.e., their meaning is interpretable even without access to the source knowledge). If not, they are deemed to be too vague or ill-formed to judge their faithfulness. Second, if the response is interpretable, the annotators are requested to evaluate whether the response is grounded on the source knowledge. If the response was deemed not faithful, we further ask the annotators to mark it as hallucination or generic.

On the other hand, if the response was deemed faithful, workers are asked to score three qualities: Cooperativeness means that the response is coherent with the previous turn and does not try to mislead the interlocutor or act unhelpfully. Engagingness involves engaging the interlocutor by prompting further replies and moving the conversation forward. Abstractiveness measures the ability to reuse information from the source knowledge in a novel way. To enable flexibility in rating, we asked annotators to rate each quality on a Likert scale from 1 (low quality) to 4 (high quality).

---

<sup>6</sup>A low score in cooperativeness is correlated with a low score in engagingness but the opposite is not necessarily true.
Results  We evaluate responses generated by T5 as it is the best performing model in terms of automated metrics (Table 6). We provide human annotators with 200 responses, where each is scored by 3 humans raters. Results are depicted in Table 7. We measure the agreement for each of the 7 qualities separately using Krippendorff’s α and find that the agreement (0.92, 0.91, 0.88, 0.90, 0.89, 0.75, 0.85 respectively) is reliably high.

Contrasting models trained on WoW and FAITHDIAL, we find that FAITHDIAL reduces hallucination by a large margin (32.6%) while increasing interpretability. Also, we observe that training models on FAITHDIAL enhances the cooperativeness, engagingness, and abstractiveness of responses, as they tend to prompt further conversations, acknowledge previous utterances, and abstract information from the source knowledge. We see that CTRL benefits faithfulness but at the expense of cooperativeness and abstractiveness of the responses. The best performing model corresponds to T5-INFORMATION, which achieves the highest faithfulness percentage (77.4%) and the highest dialogue quality scores.

Evaluation of unanswerable questions  To evaluate the ability of models trained on FAITHDIAL to handle unanswerable questions, we analyze the responses for 200 unanswerable questions sampled from the test data. Each response is manually evaluated by 3 annotators whether the answer is appropriate. Inter-annotator agreement based on Krippendorff’s alpha is 0.9 which is substantially high. Results indicate that T5-INFORMATION trained on FAITHDIAL substantially outperform T5-LOSSTRUNCATION trained on WoW in answering properly unanswerable questions (83.2% vs. 33.3%). Table 8 shows examples of unanswerable questions with responses.

4.2.4 Transfer from FAITHDIAL to other datasets

To further examine the usefulness of FAITHDIAL in out-of-domain (OOD) setting, we test the performance of T5-FAITHDIAL on TopicalChat (Gopalakrishnan et al., 2019) and CMU-DoG (Zhou et al., 2018), and WoW (Dinan et al., 2018). Contrary to WoW, speakers in CMU-DoG and TopicalChat can similarly take asymmetric roles but also symmetric roles (i.e., both act as the wizard). Knowledge is provided from Wikipedia movie articles in CMU and from diverse sources—such as Wikipedia, Reddit and news articles—in TopicalChat. The former two evaluations are in a zero-shot setting as the corresponding training sets are not part of FAITHDIAL. Results are depicted in Table 9. Since these testing benchmarks are fraught with hallucinations (see Table 1), we do not compare the quality of the response r with respect to the gold response g and report only hallucination metrics.

In this regard, the models trained on FAITHDIAL are far more faithful than the models trained on in-domain data despite the distribution shift. For example, T5-FAITHDIAL tested on CMU-DoG test data decreases hallucination by 73.7 points on Critic, by 9.8 points on $Q^2$-NLI and by 5.9 points on F1. Similar trend can be observed for TOPICALCHAT and WoW (except for F1 on WoW but human evaluation in Table 7 already shows humans prefer FAITHDIAL models by a large margin). The F1 scores for in-domain models on TOPICALCHAT and CMU-DoG are extremely low (6.6 and 1.9) indicating a high degree of hallucination. However, these are enhanced when training on FAITHDIAL.

attention from the NLP community (Ji et al., 2022). Tasks include data-to-text generation (Wiseman et al., 2017; Parikh et al., 2020), machine translation (Raunak et al., 2021; Wang and Sennrich, 2020), summarization (Durmus et al., 2020; Kang and Hashimoto, 2020), generative question answering (Li et al., 2021) and dialogue generation (Dziri et al., 2021a; Rashkin et al., 2021b).

These works focus on either devising automatic metrics to identify when hallucination occurs (Wiseman et al., 2017) or finding possible causes for this degenerate behaviour, including out-of-domain generalization and noisy training data points (Kang and Hashimoto, 2020; Raunak et al., 2021) and exposure bias caused by MLE training (Wang and Sennrich, 2020).

Hallucination in Dialogue Systems. Hallucinations in knowledge-grounded neural dialogue generation is instead a nascent research problem (Roller et al., 2021; Mielke et al., 2020; Shuster et al., 2021; Dziri et al., 2021a; Rashkin et al., 2021b). Existing work aims predominantly to address hallucinations via engineering loss functions or enforcing consistency constraints, for instance by conditioning generation on control tokens (Rashkin et al., 2021b), by learning a token-level hallucination critic to flag problematic entities and replace them (Dziri et al., 2021a), or by augmenting the dialogue system with a module retrieving relevant knowledge (Shuster et al., 2021).

Although promising, these approaches are prone to replicate—or even amplify—the noise found in training data. Dziri et al. (2022) demonstrated that more than 60% of three popular knowledge-grounded dialogue benchmarks are rife with hallucination, which is picked up even by models designed to increase faithfulness. To the best of our knowledge, FAITHDIAL is the first dataset for information-seeking dialogue that provides highly faithful curated data.

Hallucination Evaluation. Recently introduced benchmarks can serve as testbeds for knowledge grounding in dialogue systems, such as BEGIN (Dziri et al., 2021b), DialFact (Gupta et al., 2021), and Attributable to Identified Sources (AIS) framework (Rashkin et al., 2021a). Meanwhile, a recent study has reopened the question of the most reliable metric for automatic evaluation of hallucination-free models, with the Q2 metric (Honovich et al., 2021) showing performance comparable to human annotation. In this work, we further contribute to this problem by proposing a critic model—trained on our collected FAITHCRITIC data—that achieves high performance on the above-mentioned BEGIN benchmark.

6 Conclusions

We release FAITHDIAL, a new benchmark for faithful information-seeking dialogue, where a domain-expert bot answers queries based on gold-standard knowledge in a conversational manner. Examples are created by manually editing hallucinated and uncooperative responses in Wizard of Wikipedia (WoW), which constitute 79.1% of the original dataset. Leveraging the resulting high-quality data, we train both a hallucination critic, which discriminates whether utterances are faithful to the knowledge and achieves a new state of the art on BEGIN, and several dialogue generation models. In particular, we propose strategies to take advantage of both noisy and cleaned data, such as intermediate fine-tuning on WoW and an auxiliary contrastive objective. With both automated metrics and human evaluation, we verify that models trained on FAITHDIAL drastically enhance faithfulness and abstractiveness, both in-domain and during zero-shot transfer to other datasets for information-seeking dialogue, such as TopicalChat and CMU-DoG.

A AMT Instructions

Here, we detail the instructions given to workers in the annotation task. We follow instructions from (Dziri et al., 2022) in determining BEGIN and VRM categories. And, according to the identified category, we ask workers to perform a particular edit. Here are the questions we ask in every HIT:

1. Does the Bot’s response contain other information that is NOT supported by $K$? (E.g., facts, opinions, feelings) (Yes/No)
   (a) If the response is hallucinated, what is the type of the unsupported information? (options: expressing a personal experience, expressing an opinion, expressing feelings, expressing unsupported facts, giving advice, acknowledging information from the human) (Yes/No)
   (b) Was the unsupported information triggered by a question/opinion from the Human? (Yes/No)
   (c) Besides unsupported information, does the Bot’s response contain thoughts/opinions/feelings/facts that are supported by $K$? (Yes/No)
   (d) Modify the Bot’s sentence such that the response:
      i. uses ONLY the facts from $K$ to make the response informative.
      ii. is not a copy paste from $K$ but a paraphrase of it.
      iii. is relevant to the previous utterance and cooperative with the Human.

2. If not hallucinated, does the Bot’s response express personal thoughts/opinions/feelings that are supported by $K$? (Yes/No)

3. If not hallucinated, does the Bot’s response contain factual/objective information that is supported by $K$? (Yes/No)

4. If the answer is “No” to (e) and (f), the response is flagged as generic. Modify the Bot’s sentence such that the response is supported by $K$.

5. If not generic, is the Bot’s response cooperative with the Human’s response? i.e., the Bot does not ignore answering a question, or does not act in an unhelpful way.

B AMT Data Quality

To be eligible for the task, workers have to be located in the United States and Canada and have to answer successfully 20 questions as part of a qualification test. Before launching the main annotation task, we perform a small pilot round (~60 HITS) to check the performance of the workers. We email workers who commit errors, providing them with examples on how to fix their mistakes in future HITS. We also encourage the workers to reach out to us in case there is a confusion about a particular example. At the end of the pilot round, we revoke access for workers who provide poor quality annotations. Next, we launch the main annotation stage (batch size ~ 400 HITs). We continue evaluating the performance of the workers daily and reject poor quality work. Repeated mistakes result in the worker being blocked from the task entirely. In total, we ended up with 4 workers annotating the 50k utterances. We also perform an automatic quality control enforcing workers to avoid copying segments from the source knowledge. Edited utterances have to pass a n-gram overlap checker; the maximum number of copied grams has to be less than 4.

C Pay Structure

We pay crowdworkers a base pay of $1.68/HIT. To retain excellent workers for all rounds, we give a bonus of $35 – $40 per 100 HITs that are submitted successfully. The average amount of time spent per HIT is 6 min, i.e., in one hour, workers are able to complete 10 HITS. This is equivalent to $17 – $18 per hour.

D Abstractiveness strategies

We annotate manually 150 responses to explore the techniques used by the WIZARD to derive and represent information from the knowledge source $K$. Table 10 shows the different abstractiveness types with their frequencies:
**Inference** corresponds to information which can be derived from the evidence with an intermediate step in reasoning; in other words, it involves inferring obvious but implicit information from $K$, from the Apprentice utterance, or from commonsense knowledge. It encompasses *implicatures* (e.g. replace “She finished some of her work” with “She did not finish all of her work”), *presuppositions* (e.g. replace “She stopped smoking” with “She used to smoke”), and *deductions* (e.g. replace “She drove her car to work every day for 3 years” with “She can drive”). Also, it includes *commonsense knowledge* (e.g. replace “Elvis, the artist, . . . ” with “Elvis, a person, . . . ”).

**Rewording** involves the replacement of words/phrases in $K$ with similar wording. One instance of Rewording is *synonymization*, where words/phrases are replaced with their synonyms (e.g. replace “can lead to” with “can result in”). Also, it is sometimes possible to preserve truth while replacing words/phrases denoting subset members with their supersets, as in *generalization* (e.g. replace “Some dogs” with “Some animals”), or superset members with their subsets, as in *specification* (e.g. replace “all animals” with “all dogs”). Lastly, *pronominalization* replaces pronouns with noun phrases, or vice versa (e.g. replace “Andy visited Mary” with “Andy visited her”).

**Restructuring** corresponds to restructuring the syntactic formulations (syntax) of $K$ in a meaning-preserving manner. It can be done through passivization (e.g. replace “Andy visited Mary” with “Mary was visited by Andy”). Another type of Restructuring is *reordering*, the rearranging of list elements. *Ellipsis* refers to the ellipsis of sentences or the expanding of ellipted sentences (e.g. replace “I have not heard of Elvis” with “I have not”). *Questioning* refers to the restructuring of declarative statements into questions.

**Abridging** refers to the removal of modifiers and/or optional complements while preserving the entailment relationship between $K$ and the response. This includes removing *adjectives*, *adverbs*, and *independent clauses* (e.g. replace “I’m taking the red bus early today, in 10 minutes” with “I’m taking the bus today”).

**Bridging** involves adding words/phrases to connect or introduce parts of the utterance (e.g. “So . . . ”, “In other words, . . . ”, “In addition, . . . ”, etc).

### E Implementation Details

**Critic** We implement all our critics using the Huggingface Transformers library (Wolf et al., 2020). We train all models for 10 epochs, using a batch size of 32 and the Adam optimizer (Kingma and Ba, 2015) with a learning rate of $1 \times 10^{-5}$. We warm up the learning rate for 6% of the training steps followed by a linear decay.

**Generation Models** We implement all the baselines using the Huggingface Transformers library (Wolf et al., 2020) and the Pytorch-lightning library. We train our models for 10 epochs on a batch size of 32 via accumulating gradients for 4 steps, and use Adam with a learning rate of $6.25 \times 10^{-5}$ that warms up for 4% of training steps, followed by a linear decay. The models are evaluated twice per epoch on the validation set, and the best performing model is saved for testing. We early stop the training with a patience of 5. The maximum dialogue history length is set to 3 utterances. For DoHA (Prabhumoye et al., 2021), we follow the same hyperparameters, used in the paper. More specifically, DoHA is trained for 25 epochs using an Adam optimizer with a learning rate of $2 \times 10^{-5}$, a warm-up ratio of 0.1, and accumulating gradients for 8 steps. For CTRL, the code is not publicly available. We were able to reproduce the results ourselves by following training implementations in the paper and exchanging discussions with the authors. Training for all models is done on an Nvidia V100 GPU 32GB and for inference, we use nucleus sampling with $p=0.6$.

The name ‘Track and Field’ is derived from the sport’s typical venue: a stadium with an oval running track enclosing a grass field where the throwing and jumping events take place.

Did you know that the name Track and Field comes from its typical venue? That’s a stadium with a grass field inside of it and a running track.

The earliest precursor to the modern rap is the West African griot tradition, in which “oral historians”, or “praise-singers”, would disseminate oral traditions and genealogies, or use their formidable rhetorical techniques for gossip or to “praise or critique individuals.”

I don’t have any specific recommendations for rap artists. I do have some history. Rap’s precursor is called griot. Rap’s precursor is called griot, from West Africa.

Among other licensing requirements, different countries require pharmacists to hold either a Bachelor of Pharmacy, Master of Pharmacy, or Doctor of Pharmacy degree.

I can also tell you that degrees like Bachelor of Pharmacy and Doctor or Master of Pharmacy can be required by different countries.

Use by a wider audience only came in 1995 when restrictions on the use of the Internet to carry commercial traffic were lifted.

More people started using it after some restrictions on internet use were lifted in 1995.

Homebrewing is the brewing of beer on a small scale for personal, non-commercial purposes.

Interesting that you’ve done homebrewing before. So you just brew enough for yourself?

---

**Table 11:** A dialogue example showing the process of editing WOW utterances to convert them to FAITHDIAL utterances. The green utterances forms the final FAITHDIAL dialogue. Text highlighted in red indicates hallucinated content.

**Knowledge:** Boredom is also understood by scholars as a modern phenomenon which has a cultural dimension.

**Wizard:** Yes most definitely. Boredom is a modern phenomenon throughout various cultures and it takes a lot of effort to conquer it. (Partial hallucination)

**Apprentice:** With everything in the world at our fingertips, I suppose it is silly to even say that I am bored. I guess I should feel grateful. (incoherent with previous turn)

**Seeker:** That’s pretty interesting, I didn’t know that. You know, with everything in the world at our fingertips, I suppose it is silly to even say that I am bored. I guess I should feel grateful. How did it get examined by researchers anyway?

**Knowledge:** In “Experience Without Qualities: Boredom and Modernity”, Elizabeth Goodstein traces the modern discourse on boredom through literary, philosophical, and sociological texts to find that as “a discursively articulated phenomenon...boredom is at once objective and subjective, emotion and intellectualization — not just a response to the modern world but also a historically constituted strategy for coping with its discontents.”

**Wizard:** I agree. It’s a state of mind we at times may feel, but in reality it is just a way for us to cope with things we face in life (i.e, emotion, objective, subjective, etc..) (incoherent with previous turn, hallucination)

**Expert:** I cannot say how they all did it but one such person, Elizabeth Goodstein, looked at it through various forms of texts like philosophical ones.

---
Football is a family of team sports that involve, to varying degrees, kicking a ball to score a goal. Unqualified, the word football is understood to refer to whichever form of football is the most popular in the regional context in which the word appears. Sports commonly called football in certain places include association football (known as soccer in some countries); gridiron football (specifically American football or Canadian football); Australian rules football; rugby football (either rugby league or rugby union); and Gaelic football. These different variations of football are known as football codes.

The University of Iowa’s locker room for visiting football teams is completely painted pink. In the 1960’s top bowlers made twice as much as top football stars. The highest score ever in a football game occurred in 1916 when Georgia Tech defeated Cumber and 222-0 ESPN won an emmy for the creation of the superimposed yellow line representing the first down line for American football games. Former Patriots RB BenJarvus Green-Ellis has never fumbled the football in his NFL career.

History
Did you know that the University of Iowa’s locker room is painted pink? I wonder why?

T5-FaithDIAL
I don’t know honestly. A room is painted pink? that’s interesting. Speaking of football, did you know that the highest score in football appeared in 1916? (Faithful)

T5-TopicalChat
That is pretty funny, I guess the visiting team gets a lot of attention from them, I think they are scared of the pink locker room. (Hallucination)

CMU-DoG
Knowledge:
Cast: Lindsay Lohan as Cady Heron, Rachel McAdams as Regina George, Lacey Chabert as Gretchen Wieners, Amanda Seyfried as Karen Smith, Lizzy Caplan as Janis Ian. critical response: Boasts a one-two-three punch in star Lindsay Lohan, screenwriter Tina Fey and director Mark Waters, and, indeed, it delivers a knockout. The screenplay was highly praised by critics with Peter Travers of Rolling Stone calling it ‘comic gold’. In November 2012, Rotten Tomatoes named it in its ‘Top 50 Greatest Teen Comedies’. Director: Mark Waters. Genre: Comedy, teen introduction: Mean Girls is a 2004 American teen comedy film directed by Mark Waters and written by Tina Fey. The film is partially based on Rosalind Wiseman’s 2002 non-fiction self-help book Queen Bees and Wannabes, which describes female high school social cliques and the damaging effects they can have on girls. MovieName: Mean Girls rating: Rotten Tomatoes: 84% and average: 6.9/10. Metacritic Score: 66/100. CinemaScore: A year: 2004.

History:
I think Rachel McAdams had an even better role as Regina George however!

T5-FaithDIAL:
That’s great. Did you know it was written by Tina Fey? That’s being said, the movie is based on a 2002 book called Queen Bees and Wannabes about social cliques in high school? It’s also a comedy film. It’s a 2004 film, directed by Mark Waters. (Faithful)

T5-CMU-DoG:
I think it was really good. I bet it will win the Oscars. (Hallucination)
