The total decay widths of charmed baryons, including all the possible open-flavor decay channels, are calculated by means of the $^3P_0$ model. Our calculations consider in the final states: the charmed baryon-(vector/pseudoscalar) meson pairs and the (octet/decuplet) baryon-(pseudoscalar/vector) charged meson pairs, within a constituent quark model. Furthermore, we calculate the masses of the charmed baryon ground states and their excitations up to the D-wave in a constituent quark model, both in the three-quark and in quark-diquark schemes, utilizing a Hamiltonian model based on a harmonic oscillator potential plus a mass splitting term that encodes the spin, spin-orbit, isospin, and flavor interactions. The parameters of the Hamiltonian model are fitted to experimental data of charmed baryon masses and decay widths. As the experimental uncertainties of the data affect the fitted model parameters, we have thoroughly propagated these uncertainties into our predicted charmed baryon masses and decay widths via a Monte Carlo bootstrap approach, which is often absent in other theoretical studies on this subject. Our quantum number assignments and predictions of mass and strong partial decay widths are in reasonable agreement with the available data. Thus, our results show the ability to guide future measurements in LHCb, Belle and Belle II experiments. Finally, the appendixes provide some details of our calculations, in which we include the flavor coupling coefficients, which are useful for further theoretical investigations into charmed baryon strong decay widths.

I. INTRODUCTION

The discovery of new baryon resonances in high-energy physics experiments always enriches our knowledge of the hadron zoo, and provides essential information to explain the fundamental forces that govern nature. In particular, the hadron mass patterns carry information regarding the way the quarks interact with one another, and provide further insight into the fundamental binding mechanism of matter at an elementary level.

The number of observed charmed baryons has increased owing to the LHCb and Belle experiments. In 2017, the LHCb collaboration announced the observation of five narrow $\Omega_c$ states in the $\Xi^+_c K^-$ decay channel \cite{1}. Later, Belle observed five resonant states in the $\Xi^+_c K^-$ invariant mass distribution and unambiguously confirmed four of the states announced by LHCb, $\Omega_c(3000), \Omega_c(3050), \Omega_c(3066)$ and $\Omega_c(3090)$, although no signal was found for the $\Omega_c(3119)$ \cite{2}. Belle also measured a signal excess at $3188$ MeV, corresponding to the $\Omega_c(3188)$ state reported by LHCb \cite{2}. In 2020, the LHCb collaboration observed three $\Xi^0_c(2923), \Xi^0_c(2939)$ and $\Xi^0_c(2965)$ states \cite{3}; however, the $J^P$ quantum numbers were not reported. These results reported by LHCb implied that the broad state $\Xi^0_c(2930)$ observed by Belle \cite{4} and BaBar \cite{5} resolves into two narrower states $\Xi^0_c(2923)$ and $\Xi^0_c(2939)$. Nevertheless, a puzzle emerges in the experimental data, since Ref. \cite{5} reported a narrow state with a central mass of about $2965$ MeV, which is close to a resonance seen by the Belle collaboration at $2970$ MeV \cite{4, 6}, and confirmed by the BaBar collaboration \cite{5}; hence, further studies are required in order to determine whether these observations correspond to different baryons or to the same one. Moreover, the available charm baryon data are limited, especially for the $\Sigma_c$ resonances; indeed, only three states reported are by the PDG \cite{7}, $\Sigma_c(2455), \Sigma_c(2520)$ and $\Sigma_c(2800)$, while new analyses are being carried out in this sector \cite{8}. More recently in 2021, the Belle collaboration measured the spin and parity of the $\Xi_c(2970)$ state to be $J^P = 1/2^+$ \cite{9}, under an assumption that the lowest partial wave dominates the decay.

With regard to theory, the application of the non-relativistic quark model to the light baryon spectrum
owes its origins to the pioneering investigations by Is-
gur and Karl [12, 13], which were further extended in
14 to the Λc and Σc baryons and to the Λb and Σb
baryons in [15]. Over the last few years, interest
in heavy-light baryon spectroscopy has grown once more.
Examples of the recent ample literature on theoretical
investigations into heavy baryon spectroscopy are: the
report of the QCD-motivated relativistic quark-diquark
model based on the quasi-potential approach [16, 17], the
non-relativistic quark model [14, 18–20], and the QCD
model based on the quasi-potential approach [16, 17], the
QCD sum rules in the framework of the heavy quark effective
theory (HQET) [21, 22]. Alternative discussions employing
other models can be found in Refs. [25, 26], and lattice
QCD studies in Refs. [30, 33]. For extra references see
the review articles [34, 38]. Nevertheless, no model is
capable of describing the complete baryon spectrum.
Indeed, only few data determine the quantum numbers
for the charm-baryon states; some of these kinds of as-
signments, are yet unmeasured, have been extracted from
quark model predictions from the PDG [1]. Furthermore,
it is unclear whether the heavy baryons behave as quark-
diquark or three-quark systems. Thus, a full understand-
ing of the internal structure of the charmed baryons still
requires thorough theoretical and experimental studies.

Numerous studies have been conducted on the heavy
baryon decay widths. Nevertheless, a complete calcula-
tion of all charm-baryon partial strong decay widths
for ground and excited states up to the D-wave shell
within the same model has never been performed. For
example, within the framework of the chiral quark mod-
els in Ref. [31], only the open-flavor strong decay widths
Λc → Σcπ,D0p and Σc → Λcπ,Σcπ,D0p were calcu-
lated. Additionally, in Ref. [41] the Ξc strong decays
were considered up to the D-wave shell, while no predic-
tions of the other charmed baryon decays were made. In
Ref. [41] the authors calculated the S- and P-wave decay
widths heavy baryons; however, their analysis was lim-
ited to baryons decaying only into ground-state charmed
baryons plus pseudoscalar mesons. Moreover, no D-wave
or radial excitations were reported. In the framework of
the heavy hadron chiral perturbation theory in Ref. [12],
certain decays of charmed baryons Λc, Σc and Ξc baryons
were computed although these calculations did not in-
clude the charmed baryon-vector meson channels and
did not give predictions for the Ωc states. In Ref. [13]
the calculations were performed only for the S- and P-
wave Λc, Σc and Ξc states that decay into a ground-state
charmed baryon plus a pion. Adopting a non-relativistic
quark model, Ref. [14] evaluated only the decay widths
of the charmed baryons Λc∗(2595), Λc∗(2625), Λc∗(2765),
Λc∗(2880) and Λc∗(2940) into Σc(2455)π and Σc(2520)π, and
of Σc(2455) and Σc(2520) into Λcπ, were evaluated.
In a more recent work [15], the same decay widths were
calculated by adding relativistic corrections, and the pre-
vious analysis was extended to the decay widths of bot-
tom baryons. In the context of the elementary emission
model [16], the strong and radiative decays of charmed
and bottom baryons were investigated. However, the
study was restricted to the low-lying λ-mode D-wave
excitations and the charmed baryon-vector meson chan-
nels or the charmed meson-octet/decuplet baryon chan-
nels were not included. In the framework of QCD sum
rules in Ref. [17], the author studied only the P-wave
Λc → Σc + π and the P-wave Λc electromagnetic
decays, while in [48] the authors calculated the P-
wave charmed baryon decays into ground-state charmed
baryons accompanied by a pseudoscalar meson. In [49],
the 3P0 model was applied to calculate the strong dec-
ays of Λc, Σc, and Ξc excited states up to the D-
wave shell. Nevertheless the decay widths into charmed
baryon-vector mesons were not calculated, nor was the
Ωc sector considered. The 3P0 model was also applied in
50, 52. In these references, however only the Λc decays
were studied. In [20], the Eichten, Hill and Quigg formu-
a, in combination with the 3P0 model, was applied in
order to calculate the 1P and 2S Λc, Σc and Ξc decays
into charmed baryon and pseudoscalar mesons.

In Ref. [53], prompted by the observation of the five Ωc
by LHCb [1], we calculated the Ωc decay widths in the
Ξc K− and Ξc K− channels within the 3P0 model.
In that study, we also calculated the Ωb decay widths in
the Ξb K− and Ξb K− channels and gave predictions
for the mass spectra of both Ωc and Ωb ground states and
P-wave excitations. Subsequently, in Ref. [53], we
extended our model to the Ξc′ states and calculated
the mass spectra and the strong partial decay widths
of the Ξc′-ground states and -P-wave excitations into
ΣcK, Σc K, Σc K, Λc K, Λc π and Ξc η and of the
Σc ground states and -P-wave excitations into Σc K,
Σc η, Σb K, Λb K, Ξb π and Ξb η, within both the
Elementary Emission Model (EEM) and the 3P0 model.
In the present article we further extend our model to the
whole charm-baryon states (cqg, cqs and css systems) by
employing the same mass formula originally introduced in
Ref. [53]. Additionally, in the present paper, the pa-
rameters of the model are fitted in order to globally repro-
duce all the available charm-baryon experimental states.
The experimental uncertainties are also propagated to
the model parameters by means of the Monte Carlo boot-
strap method [55], which is an advanced method used
to properly estimate the error propagation by taking
into account the correlation between the fitted param-
eters. In this way, we perform a global fit of a single
model, in which the same set of parameters predicts the
charm-baryon masses and strong partial decay widths in
all the possible open decay channels up to the D-wave
shell. Moreover, considering the well-established obser-
vation by Isgur and Karl in Ref. [12] that the harmonic
oscillator wave functions are a good approximation of the
eigenfunctions of low-lying states, and also taking into
account that the calculations of the strong decay widths
are barely sensitive to the specific model used [54], our strong
partial decay width predictions are the most complete
calculations in the charm-baryon sector to date. The
paper is organized as follows: In Sec. I we introduce the
details of the methodology used to construct the charm-baryon states and to calculate the mass spectra and decay widths. The theoretical details for the calculation of the charm-baryon mass spectra include contributions due to spin-orbit-, spin-, isospin- and flavor-dependent interactions. Thus, we develop a formalism for obtaining the $S$-, $P$- and $D$-wave charm-baryon mass spectrum. We also describe the calculation of the total-decay-width of the charm baryons via the $^3P_0$ model by computing the partial-decay-width of all the open-flavor channels. In section III, we carefully study the parameters of the mass formula presented in Ref. [53] and perform a global fit to uncertainties, as propagated by means of the bootstrap method. In Sec. IV, we present the masses and widths of all charm-baryons up to $^3D_2$-wave charm-baryon mass spectrum. We also describe the calculation of the total-decay-width of the charm baryons via the $^3P_0$ Hamiltonian, $H_{\text{h.o.}}$, plus a perturbation operator that describes the spin, spin-orbit, isospin and flavor dependences of the mass splittings:

$$H = H_{\text{h.o.}} + P_s S^2 + P_{sl} S \cdot L + P_I I^2 + P_f C_2(\text{SU}(3)_f),$$

$$S, L, I \text{ and } C_2(\text{SU}(3)_f) \text{ are the spin, orbital momentum, isospin and Casimir operators, respectively. This perturbation term contributes to the charm-baryon mass by adding the usual } S, L, I \text{ and } C_2(\text{SU}(3)_f) \text{ eigenvalues weighted with the model parameters } P_s, P_{sl}, P_I \text{ and } P_f, \text{ as indicated in Eq. 1. Notice that our mass formula in Eq. 1 is independent of } I_z, \text{ the isospin projection; therefore, the charge channels are degenerated in this model.}$$

For the case in which the baryon is modeled as a three-quark system, the three-dimensional h.o. Hamiltonian reads as,

$$H_{\text{h.o.}} = \sum_{i=1}^{3} m_i + \frac{P_s^2}{2m_s} + \frac{P_{sl}^2}{2m_{sl}} + \frac{1}{2} \mu \omega^2 \rho^2 + \frac{1}{2} m_\lambda \omega^2 \lambda^2 \tag{2}$$

written in terms of Jacobi coordinates, $\rho$ and $\lambda$, and conjugated momenta, $p_\rho$ and $p_\lambda$. The $H_{\text{h.o.}}$ eigenvalues are

$$\sum_{i=1}^{3} m_i + \omega_\rho n_\rho + \omega_\lambda n_\lambda; \text{ with } \omega_\rho(\lambda) = \sqrt{\frac{3K_c}{m_\rho(\lambda)}}, \tag{3}$$

where $m_i$ are the constituent quark masses, $m_1$ and $m_2$ correspond to the light quarks and $m_3$ to the charm quark; $m_\rho$ is defined as $m_\rho = (m_1 + m_2)/2$, and $m_\lambda = 3m_\rho m_3/(2m_\rho + m_3)$. We use the well-known definitions for $n_\rho(\lambda) = 2k_\rho(\lambda) + l_\rho(\lambda)$, $k_\rho(\lambda) = 0, 1, ...$, and $l_\rho(\lambda) = 0, 1, ...$; here, $l_\rho(\lambda)$ are the orbital angular momenta of the $\rho(\lambda)$ oscillators, and $k_\rho(\lambda)$ is the number of nodes (radial excitations) in the $\rho(\lambda)$ oscillators. $K_c$ is the spring constant.

Additionally, we present a simplification of the three-quark system that utilizes only one relative coordinate $r$ and momentum $p_r$, namely, the quark-diquark system. Here, the two light quarks are regarded as a single diquark object. The quark-diquark Hamiltonian reads as,

$$H_{\text{h.o.}} = m_D + m_c + \frac{p_r^2}{2\mu} + \frac{1}{2} \mu \omega^2 r^2, \tag{4}$$

with $p_r = (m_c p_D - m_D p_c)/(m_c + m_D)$. The $H_{\text{h.o.}}$ eigenvalues are

$$m_D + m_c + \omega_r n_r; \text{ with } \omega_r = \sqrt{\frac{3K_c}{\mu}}, \tag{5}$$

where $m_D$ is the diquark mass, $m_c$ is the charm quark mass; $\mu$ is the reduced mass of the system, and is defined as $\mu = m_c m_D/(m_c + m_D)$; $n_r$ and $K_c$ are defined as in the three-quark system.

**II. METHODOLOGY**

**A. Mass spectra of charmed baryons**

The masses of the charm-baryon states are calculated as the eigenvalues of the Hamiltonian system. The charm-baryon states are described in accordance with the formalism of Ref. [52], i.e., the charm-baryon system is modeled with a three-dimensional harmonic oscillator (h.o.) Hamiltonian, $H_{\text{h.o.}}$, plus a perturbation operator that describes the spin, spin-orbit, isospin and flavor dependences of the mass splittings:

$$H = H_{\text{h.o.}} + P_s S^2 + P_{sl} S \cdot L + P_I I^2 + P_f C_2(\text{SU}(3)_f),$$

In the three-quark model, the baryon states are characterized by means of a $qqQ$ system, where $Q = c$ and $q = u, d, s$. The three-quark Hamiltonian in Eq. 2 is expressed in terms of two coordinates, $\rho$ and $\lambda$ [57], that encode the spatial degrees of freedom of the system with associated effective masses, $m_\rho$ and $m_\lambda$. Note that in heavy-light baryons, for which $m_\rho \ll m_\lambda$, the two excitation modes can be decoupled from each other as long as the heavy-light quark mass difference is significant.

In the quark-diquark system, the baryon states are characterized by means of a $DQ$ system, where $Q = c$ and $D = D_{13}, D_{23}, D_{33}, D_{3D}, D_{3C}, D_{3A}$ are the diquarks that correspond to the $\Omega_c$, $\Xi_c^0(\Xi_c)$, $\Sigma_c$ and $\Lambda_c$ baryons, respectively. The
quark-diquark Hamiltonian in Eq. [4] is expressed in terms of one spatial coordinate \( r \) with an associated reduced mass \( \mu \); i.e., the quark-diquark system resembles a diatomic molecule.

We construct the ground and excited states in order to establish the quantum numbers of the charm-baryon states. We consider that a single quark is described by its spin, flavor, color and spatial degrees of freedom. Moreover, in our models, the light quarks behave as identical particles; hence, we take into account the Pauli principle, which postulates that the wave function of identical fermions must be anti-symmetric in order to achieve particle exchange. Thus, the \( qq \) spin-flavor and orbital wave functions have the same permutation symmetry: symmetric spin-flavor in the \( S \)-wave or \( D \)-wave, or anti-symmetric spin-flavor in the anti-symmetric \( P \)-wave. Two light quarks are necessary in the \( 6_f \) or anti-\( 3_f \) flavor-symmetric state.

Formally, a three-quark (quark-diquark) quantum state, written as \( |l_\lambda(l_r), l_\rho, k_\lambda(k_r), k_\rho, \rangle \), is defined by its total angular momentum \( J_{\text{tot}} = L_{\text{tot}} + S_{\text{tot}} \), where \( L_{\text{tot}} = l_\rho + l_\lambda \) \( \langle L_{\text{tot}} = l_\lambda \rangle \) and \( S_{\text{tot}} = S_l + \frac{1}{2} \). \( S_l \) is the coupled spin of the light quarks and the number of nodes is \( k_\lambda, k_\rho(k_r) \). In addition, in order to unambiguously define these quantum states, we assign to them the flavor \( F \) and spectroscopy \( 2S+1L_J \) representations. In the following paragraphs, we will construct the possible states for the two different flavor representations available for the charmed baryons, in the energy bands \( N = n_\rho + n_\lambda \) \( (N = n_l) \) and \( N = 0,1,2 \) in order to find \( S-, P-, D\)-wave charm-baryon states.

1. The symmetric \( 6_f \)-multiplet for the three-quark model

The \( \Omega_c, \Xi'_c \), and \( \Sigma_c \) baryons form a flavor sextet in the charm-baryon sector. These charmed baryons have a symmetric flavor-wave function and, in combination with the anti-symmetric color-wave function, the final product wave function is anti-symmetric. This implies that the product of the spatial and spin-wave functions of the light quarks should be symmetric. In the energy band \( N = 0 \), if \( l_\rho = l_\lambda = 0 \), the spatial wave function of the two light quarks is symmetric. That is, these states have a symmetric-spin wave function, meaning \( S_l = 1 \). Hence, two ground states, \( J_{\text{tot}} = S_{\text{tot}} = 1/2,3/2 \), exist. For the energy band \( N = 1 \), there are two different possibilities. If \( l_\rho = 0 \) and \( l_\lambda = 1 \), we again have spatial-symmetric wave functions under the interchange of light quarks, which must be coupled with two possible spin configurations, \( S_{\text{tot}} = 1/2,3/2 \), with \( L_{\text{tot}} = 1 \), yielding five \( P_\lambda \)-wave excitations. If \( l_\rho = 1 \) and \( l_\lambda = 0 \), the spatial wave function is anti-symmetric under the interchange of light quarks implying that the spin wave function should be anti-symmetric, meaning \( S_l = 0 \), which yields two \( P_\rho \)-wave states obtained from \( J_{\text{tot}} = 1 + 1/2 = 1/2,3/2 \). In the energy band \( N = 2 \), when \( l_\rho = 0 \) and \( l_\lambda = 2 \), the spatial wave function is symmetric. Thus, it must be combined with two possible spin configurations, \( S_{\text{tot}} = 1/2,3/2 \), obtaining six \( D_\rho \)-wave excitations. Additionally, there are radial excitation modes in this band. For the case \( k_\rho = 0 \) and \( k_\lambda = 1 \), the spatial wave function is symmetric. Thus, the spin wave function must also be symmetric, yielding two \( \lambda \)-radial excitations, \( J_{\text{tot}} = S_{\text{tot}} = 1/2,3/2 \), since \( L_{\text{tot}} = 0 \). The same situation appears when \( k_\rho = 1 \) and \( k_\lambda = 0 \); the spatial wave function is symmetric. Thus, there are two \( \rho \)-radial excitations, corresponding to \( J_{\text{tot}} = S_{\text{tot}} = 1/2,3/2 \). In the case \( l_\rho = 1 \) and \( l_\lambda = 1 \), which yields \( L_{\text{tot}} = 2,1,0 \), the product of spatial wave functions is anti-symmetric, implying that we have to couple it with the anti-symmetric spin configurations, \( S_{\text{tot}} = 1/2 \), thus obtaining five possible states: two \( D \)-wave states, two \( P \)-wave states, and one \( S \)-wave state. Finally, if \( l_\rho = 2 \) and \( l_\lambda = 0 \), the spatial wave functions are symmetric. Hence, we have to combine them with \( S_{\text{tot}} = 1/2,3/2 \), obtaining six \( D_\rho \)-wave excitations.

2. The symmetric \( 6_f \)-multiplet for the quark-diquark model

When the \( \Omega_c, \Xi'_c \), and \( \Sigma_c \) baryons are seen as quark-diquark systems, the two constituent light quarks of the diquark are considered to be correlated, with no internal spatial excitations (\( S \)-wave); i.e., it is hypothesized that we are within the limit where the diquark internal spatial excitations are higher in energy than the scale of the resonances studied. Since the hadron must be colorless, the diquark transforms as \( 3 \) under \( SU_c(3) \); thus, the product of the spin and flavor wave functions of the diquark configuration should be symmetric. The flavor wave functions of the \( 6_f \) representation are symmetric. As a result, we can only combine with axial-vector diquarks; that is, with \( S_l = 1 \). For the energy band \( N = 0 \), \( L_{\text{tot}} = 0 \), and thus \( J_{\text{tot}} = S_{\text{tot}} = 1/2,3/2 \), yielding two ground states. In the next band \( N = 1 \), \( L_{\text{tot}} = 1 \) has to be coupled with \( S_{\text{tot}} = 1/2,3/2 \), yielding five \( P \)-wave excitations. For the band \( N = 2 \), \( L_{\text{tot}} = 2 \), and we must combine with \( S_{\text{tot}} = 1/2,3/2 \), to get six \( D \)-wave states. Moreover, there is a radial degree of freedom \( k = 1 \); with \( L_{\text{tot}} = 0 \), we have \( J_{\text{tot}} = S_{\text{tot}} = 1/2,3/2 \), and hence find two radial excitations.

3. The anti-symmetric \( 3_f \)-plet for the three-quark model

The \( \Lambda_c \), \( \Xi'_c \), and \( \Xi_c \) baryons form a flavor-anti-triplet in the charm-baryon sector. These charmed baryons have an anti-symmetric flavor wave function, and which, in combination with the anti-symmetric color wave function, produces a symmetric combination. This implies that the product of the spatial and spin wave functions of the light quarks should be anti-symmetric. For the energy band \( N = 0 \), if \( l_\rho = l_\lambda = 0 \), the spatial wave function of the two light quarks is symmetric, thus the spin wave function should be anti-symmetric. This cor-
responds to \( S_\parallel = 0 \), producing only one ground state. For the energy band \( N = 1 \), if \( l_\rho = 0 \) and \( l_\lambda = 1 \), we have a symmetric spatial wave function; thus, the spin wave function should be anti-symmetric. It implies \( S_{\text{tot}} = 1/2 \) and, in combination with the total \( L_{\text{tot}} = 1 \), yields two \( P_\lambda \) states. If \( l_\rho = 1 \) and \( l_\lambda = 0 \), the spatial wave function of the two light quarks is anti-symmetric. Thus, the spin wave function should be symmetric, giving two possible configurations: \( S_{\text{tot}} = 1/2, 3/2 \). This, in combination with \( L_{\text{tot}} = 1 \), constructs five \( P_\rho \) states. In the energy band \( N = 2 \), in the case of \( l_\rho = 0 \) and \( l_\lambda = 2 \), the spatial wave function is symmetric; it is therefore combined with the anti-symmetric spin configuration, \( S_{\text{tot}} = 1/2 \), giving two \( D_\lambda \)-wave excitations. The two possible radial excitations, \( k_\rho = 0 \) and \( k_\lambda = 1 \), and \( k_\rho = 1 \) and \( k_\lambda = 0 \), are symmetric in the spatial wave function. They should be combined with the anti-symmetric spin configuration, \( S_{\text{tot}} = 1/2 \), producing one \( \lambda \)-radial excitation and one \( \rho \)-radial excitation. The anti-symmetric spatial wave functions of the configuration \( l_\rho = 1 \) and \( l_\lambda = 1 \) are coupled to \( L_{\text{tot}} = 0, 1, 2 \), and the angular momenta should be combined with the symmetric spin configurations \( S_{\text{tot}} = 1/2, 3/2 \), producing thirteen mixed excited states: six \( D \)-wave states, five \( P \)-wave states, and two \( S \)-wave states. Finally, the symmetric configuration \( l_\rho = 2 \) and \( l_\lambda = 0 \), combined with the anti-symmetric spin configuration, \( S_{\text{tot}} = 1/2 \), gives two \( D_\rho \)-wave excitations.

4. The anti-symmetric \( 3_1 \)-plet for the quark-diquark model

Moreover, \( \Lambda_c \) and \( \Xi_c \) baryons are described as quark-diquark systems. In this case, as discussed in subsection II.B.2, the diquark presents an \( S \)-wave configuration, given its lack of internal spatial excitations. Considering that it is \( 3 \) in the color representation \( SU(3) \), we conclude that the product of the spin and flavor wave functions of the diquark configuration should be symmetric. In the anti-symmetric \( 3_1 \)-plet, the flavor wave function is anti-symmetric; thus, the spin wave function of the diquark correspond to a scalar configuration, \( S_{\parallel} = 0 \). For the energy band \( N = 0 \), we have \( L = 0 \); thus, we only have one ground state \( J_{\text{tot}} = S_{\text{tot}} = 1/2 \). In the next band, \( N = 1 \), we must combine \( L_{\text{tot}} = 1 \) with \( S_{\text{tot}} = 1/2 \), which yields two \( P \)-wave states. In the band \( N = 2 \), we have \( L_{\text{tot}} = 1 \), and, on coupling to \( S_{\text{tot}} = 1/2 \), we get two \( D \)-wave states. Finally, with a radial excitation \( k_\tau = 1 \) and \( L_{\text{tot}} = 0 \), there is only one state.

C. Charmed baryon decay widths

The open-flavor strong decays of a charmed baryon \( A \) to another baryon \( B \) plus a meson \( C \), \( A \rightarrow BC \), have been studied by means of the \( ^3P_0 \) model. According to this model, a \( q\bar{q} \) pair is created from the vacuum when a \( q\bar{q}c \) baryon decays and regroups into an outgoing meson and a baryon via the quark rearrangement process as depicted in Fig. 1. In the present study, we consider the decay of a charmed baryon \( A \) to a charmed baryon \( B \) plus a light meson \( C \), see Fig. 1(a), and also the case in which the final state is a light baryon \( B \) plus a charmed meson \( C \), see Fig. 1(b). Within the non-relativistic limit, the transition operator is written as

\[
T^I = -3\gamma_0 \sum_m \langle 1 m; 1 - m | 0 \rangle \int d^3P_4 \, d^3P_5 \delta^3(P_4 + P_5) \times \mathcal{Y}_I^m(P_4 - P_5) \chi_{1-m}^{45}\varphi_0^{45}\omega_0^{45} \delta_{4\pm 1}^3(P_4) \, d_{3j}(P_5),
\tag{6}
\]

where 4 and 5 are the indices of the quark and antiquark created. \( \varphi_0^{45} = (\bar{u}u + \bar{d}d + s\bar{s})/\sqrt{3} \) and \( \omega_0^{45} = (\bar{r}r + \bar{b}b + g\bar{g})/\sqrt{3} \) are the flavor and color singlet-wave functions, respectively. \( \chi_{1-m}^{45} \) is the spin-triplet state. \( \mathcal{Y}_I^m(k) \equiv |k|Y_1^m(\theta_k, \phi_k) \) is a solid harmonic polynomial corresponding to the \( P \)-wave quark pair. \( \gamma_0 \) is a dimensionless constant related to the strength of the \( q\bar{q} \) pair creation vertex from the vacuum. \( \gamma_0 \) is a free parameter of the \( ^3P_0 \) model.

The total decay width \( \Gamma \) is the sum of the partial widths for the open channels \( BC \), \( \Gamma = \sum_{BC} \Gamma_{A \rightarrow BC} \), where the partial widths \( \Gamma_{A \rightarrow BC} \), are computed as

\[
\Gamma_{A \rightarrow BC} = \frac{2\pi\gamma_0^2}{2J_A + 1} \Phi_{A \rightarrow BC}(\theta_0) \times \sum_{M_{J_A};M_{J_B}} |\mathcal{M}_{M_{J_A},M_{J_B}}|^2. \tag{7}
\]

Here, \( \mathcal{M} = \langle BC|T^I|A \rangle \) is the \( ^3P_0 \) amplitude written in terms of hadron h.o. wave functions and the sum runs.
over the projections $M_{A,B}$ of the total angular momenta $J_{A,B}$ of $A$ and $B$. $q_0$ is the relative momentum between $B$ and $C$, and the coefficient $\Phi_{A\rightarrow BC}(q_0)$ is the relativistic phase space factor

$$\Phi_{A\rightarrow BC}(q_0) = \frac{E_B(q_0)E_C(q_0)}{m_A},$$

with $E_{B,C} = \sqrt{m_{B,C}^2 + q_0^2};$

where $m_A$ is the initial charmed baryon mass in its rest frame. The masses $m_B$ and $m_C$ and energies $E_B$ and $E_C$ correspond to the final baryon and meson, respectively.

The h.o. wave functions depend on the parameters $\alpha_{\rho(\lambda)},$ see [A] which, in Reference [60], are regarded as free parameters. Conversely, in the present study, $\alpha_{\rho(\lambda)}$ are related to the baryon $\rho$- and $\lambda$-mode h.o. frequencies as defined in Eq. 4 this relation is established by $\alpha_{\rho(\lambda)}^2 = \omega_{\rho(\lambda)}m_{\rho(\lambda)}$. Therefore, $\alpha_{\rho(\lambda)}$ will depend on the fit parameter $K_\rho$ and constituent quark masses. The h.o. wave functions and coordinate system conventions used in our decay width calculations are given in [A]. The decay widths are calculated for each charm-baryon type; the available open-flavor channels include all the pseudoscalar and vector mesons. The open-flavor channels share an extra parameter $R$ related to the meson size, which has been discussed extensively in the literature [61, 62]; we adopt $R = 2.1$ (GeV) which is taken from References [49, 63]. The flavor-meson wave functions are given in [A]. All the possible flavor couplings, $F_{A\rightarrow BC} = \langle \phi_B\phi_C|\phi_0\phi_A \rangle$ are given in [B]. The masses of the decay products are listed in Table XIV in [C]. It is important to mention that the application of the $3P_0$ model is restricted to the three-quark system, owing the difficulty of dealing with diquark spatial wave functions within the $3P_0$ model formalism.

III. PARAMETER DETERMINATION AND UNCERTAINTIES

A. Mass spectra of charmed baryons

We fitted a selection of experimentally observed charm-baryon states, $\Omega_c, \Sigma_c, \Lambda_c, \Xi_c$, and $\Xi_c$, to the masses predicted by Eq. 2 and Eq. 4 to obtain the constituent quark and diquark masses ($m_c, m_s, m_{u,d}, m_{D_0}, m_{D_s}$, and $m_{P_{0,\lambda}}$) and the model parameters ($P_s, P_{st}, P_l, \tilde{P}_l$ and $K_\rho$). The fitted model parameters and masses minimize the sum of the squared differences between the experimental baryon masses and those predicted by the model (least-squares method).

The measured baryon masses come with statistical and systematic uncertainties. Furthermore, the models in Eq. 2 and Eq. 4 are approximate descriptions of the charm baryons. Thus, to take into account the possible deviations of these models from the experimental observations, we assigned a model uncertainty to each model.

The model uncertainty, $\sigma_{\text{model}}$, is calculated in accordance with Ref. [9] and is such that $\chi^2/NDF \simeq 1$, where

$$\chi^2 = \sum_i \frac{(M_{\text{mod},i} - M_{\text{exp},i})^2}{\sigma_{\text{mod}}^2 + \sigma_{\text{exp},i}^2}. \quad (8)$$

$M_{\text{mod},i}$ are the predicted charm baryon masses, $M_{\text{exp},i}$ are the experimental charm baryon masses included in the fit with uncertainties $\sigma_{\text{exp},i}$, and $NDF$ is the number of degrees of freedom. We obtained $\sigma_{\text{model}} = 15.42$ MeV for the three-quark model and $\sigma_{\text{model}} = 13.63$ MeV for the quark-diquark model.

To integrate the experimental and model uncertainties into our fit, we carried out a statistical simulation of error propagation. To do so, we randomly sampled the experimental masses from a Gaussian shaped distribution with a mean equal to the central mass value and a width equal to the squared sum of the uncertainties. We fitted the model by using a sampled mass corresponding to each experimental observed state included in the fit, and we repeated the procedure 10$^4$ times. In this manner, we obtained a Gaussian distribution for each constituent quark mass, model parameter, and the baryon mass itself. Next, we assigned the mean of the distribution as the value of the parameter and used its difference from the distribution quantiles at 68% confidence level (C.L.), in order to extract the uncertainty. This method is known as the Monte Carlo bootstrap uncertainty propagation [55, 65].

The experimental masses and their corresponding uncertainties used in the fit and error propagation are marked with (*) in Tables IV-VII. These mass measurements are summarized in the PDG database [9]. However, the charm-baryon masses predicted by Eq. 2 are degenerated in comparison with different $u$ or $d$ quark configurations, since the model will assign identical masses to baryons with the same number of $u$ or $d$ quark contents. This is a consequence of isospin symmetry. That is to say,
the $\Sigma_c$ baryons are measured in the states $\Sigma_c^{++} = uuc$, $\Sigma_c^+ = udc$ and $\Sigma_c^0 = ddc$, which display small mass differences. These three states are degenerated in our model. Additionally, the same situation emerges for the states $\Xi_c^+ = usc$ and $\Xi_c^0 = dsc$, which are taken as the $\Xi_c$ baryons. As these groups of mass states have the same quantum numbers, our quantum number assignments are not affected by the mass degeneracy. In our calculations, to account for this degeneracy, we fitted the arithmetic mean of the measured masses and adopted a conservative approach to the uncertainty by defining it as the standard deviation among the measured masses, plus their highest reported experimental uncertainty. The calculations were carried out by using MINUIT and NumPy. The results of the fit are shown in Table I. The constituent quark masses obtained agree with previous theoretical determinations. Furthermore, the model parameters used in the present study are in the range of our previous work, where phenomenological considerations were considered to determine them. Tables II and III show the correlation of the fitted parameters in the three-quark and quark-diquark model, respectively. In the three-quark model, the constituent quark masses are highly correlated, indicating that the quark masses exhibit similar behavior inside the baryon. Moreover, the spring constant $K_c$ is also highly correlated with the quark masses, as expected from Eq. 3. The theoretical masses and their uncertainties are statistically simulated constituent quark masses, and $K_c$ and $\gamma_0$; each width calculation was then repeated $10^4$ times. Next, we included the experimental uncertainties of the decay products $m_B$ and $m_C$. These experimental uncertainties, the values of which are shown in Table XIV, were propagated to the decay widths by means of the same random sampling technique described for the masses. Furthermore, a model uncertainty, $\sigma_{\text{mod}} = 4.44$, was included. We set the decay width value as the population mean of the Gaussian distribution obtained, with an error equivalent to the difference between this mean and the distribution quantiles at 68% C.L. The value and uncertainty obtained are $\gamma_0 = 19.6 \pm 5.1$. These calculations are only performed when the charmed baryons are modeled as three-quark systems.

### IV. RESULTS AND DISCUSSION

In this section, we present our results regarding the mass spectra and total decay widths of charmed baryons. The mass spectra are computed via the mass formula of Eq. 7. The theoretical masses and their uncertainties are reported in the third column for the three-quark system and in the fourth column for the quark-diquark system in Tables V, VI, VII. The theoretical decay widths for the three-quark system are computed by using the $^3P_0$ model described in Sec. III C. Each open-flavor channel decay width is obtained via Eq. 2, and the total decay width is the sum over all the channels. The theoretical total decay widths and their uncertainties for the three-quark

TABLE II: Correlation between fitted parameters: three-quark system.

### B. Charm-baryon decay widths

Parameter determination and error propagation for the decay widths were carried out in analogy with the above procedure for the charm-baryon masses. The pair-creation constant $\gamma_0$ of Eq. 2 was obtained by fitting data of selected charm-baryon decay widths.

To compute the uncertainty of the decay widths, we considered all possible sources of uncertainty. First, the error coming from the baryon mass $m_A$ and parameter $K_c$ were included by calculating a decay width for all the statistically simulated constituent quark masses, $m_A$ and $K_c$ and $\gamma_0$; each width calculation was then repeated $10^4$ times. Next, we included the experimental uncertainties of the decay products $m_B$ and $m_C$. These experimental uncertainties, the values of which are shown in Table XIV, were propagated to the decay widths by means of the same random sampling technique described for the masses. Furthermore, a model uncertainty, $\sigma_{\text{mod}} = 4.44$, was included. We set the decay width value as the population mean of the Gaussian distribution obtained, with an error equivalent to the difference between this mean and the distribution quantiles at 68% C.L. The value and uncertainty obtained are $\gamma_0 = 19.6 \pm 5.1$. These calculations are only performed when the charmed baryons are modeled as three-quark systems.
system are reported in the fifth column of Tables IV-VIII. The partial-decay widths to all open-flavor channels are found in Tables XXI-XIII of F.

Our proposed quantum number assignments for the charm-baryon states are summarized in Figures 2-6 within the three-quark model. There is a good agreement between the predicted mass pattern spectrum and the experimental data. Furthermore, we present our charm-baryon spectrum on using the quark-diquark framework in Figures 7-11. In the following subsections, we discuss our assignments to the available data reported in the PDG [9].

A. Assignments of charmed baryons

First, we discuss our assignments based on our theoretical analyses of the charmed baryons $\Omega_c$, $\Xi'_c$, $\Sigma_c$, $\Xi_c$, and $\Lambda_c$. As a first criterion, we use our mass spectrum to identify the charm-baryon resonances, and the decay width as a secondary criterion. The classification for the quark-diquark model is equivalent to that of the three-quark model when we describe ground states and $\lambda$-type excitations. When states are identified as $\rho$-type excitations in the three-quark model, there are no equivalent states in the quark-diquark model (see Tables IV-VIII).

1. $\Omega_c$

Our results for the $\Omega_c$ resonances are reported in Table IV; they are in good agreement with the experimental masses reported in the PDG [9]. Our results are also consistent with our previous calculations [53]. Here we have extended our calculations up to $D$-wave states. The $\Omega_c$ and $\Omega_c'(2770)$ states are well reproduced in our model. They are identified as the ground states with quantum numbers (QN) $J^P = 1/2^+$ and $J^P = 3/2^+$; note that these QN have not been yet measured. The observed $\Omega_c(3000)$ resonance could be identified as a $P_\lambda$-wave state with $J^P = 1/2^-$, where the total-internal-spin is $S = 1/2$; our theoretical width is compatible with the experimental value. The $\Omega_c(3050)$ has an excellent match in our model; the mass is well reproduced, but the width is slightly overestimated; the $\Omega_c(3050)$ is iden-

</table>

**TABLE IV**: $\Omega_c(946)$ resonances. The flavor content is specified with an $\mathcal{F}$. The first column shows the quantum states $|l_\lambda(l_\tau),l_\rho,k_\lambda(k_\tau),k_\rho\rangle$ for the three-quark (quark-diquark) model, where $l_\lambda,\rho(k_\lambda)$ are the orbital angular momenta and $k_\lambda,\rho(k_\tau)$ the number of nodes of the $\lambda(r)$ and $\rho$ oscillators. Furthermore, $N = n_\rho + n_\lambda$ ($N = n_\tau$) separate the energy bands $N = 0, 1, 2$. The second column contains the spectroscopic notation $2S+1L_J$ for each state and is defined by the total angular momentum $J_{tot} = L_{tot} + S_{tot}$, where $S_{tot} = S_\tau + \frac{1}{2}$, and $L_{tot} = L_\lambda + I_\rho$ ($I_{tot} = I_\tau$ for the quark-diquark model). The predicted masses, computed within the three-quark model, are shown in the third column, whereas their corresponding total strong decay widths are shown in the sixth column. The predicted masses, computed within the quark-diquark framework, are presented in the fourth column. Our theoretical results are compared with the experimental masses of the fifth column and the total decay widths of the seventh column [89, 90]. The (*) indicate the experimental mass and decay width values included in the fits. The † indicates that there is no reported experimental mass or decay for that state. The †† indicates that there is no quark-diquark prediction for that state.

tified as the $J^P = 1/2^-$ state, with total-internal-spin $S = 3/2$. In our calculations, the central value deviates 20 MeV for $\Omega_c(3065)$; however, the width is overestimated. Hence, we identify the observed $\Omega_c(3065)$ as the state $J^P = 3/2^-$ with internal-total-spin $S = 1/2$. It should be noted that our state $J^P = 3/2^-$ is lighter in mass that the state $J^P = 1/2^-$; this may be a numerical consequence of the fit. However, this opens the possi-
bility of interchanging the assignments of the $\Omega_c(3050)$ and $\Omega_c(3065)$ states, with $J^P = 3/2^-$ and $J^P = 1/2^-$, respectively. Only future experiments will confirm the right order and unique assignments. The $\Omega_c(3090)$ is identified as the state $J^P = 3/2^-$ with spin $S = 3/2$; however, its theoretical mass is slightly underestimated, but the theoretical width is in good agreement with the experimental value. Finally, the mass and width of the $\Omega_c(3120)$ resonance is well reproduced in our model; it is identified as the state $J^P = 5/2^-$ with spin $S = 3/2$. This state was not confirmed by Belle [20], other interpretations are therefore possible. Since this state is very narrow, it can be described as a molecular state [20].

Our results for $\Sigma_c$ states are reported in Table IV. There are only three experimentally observed $\Sigma_c$ states, all of which have masses that are in excellent agreement with our predictions. $\Sigma_c(2455)$ is identified as the ground state $J^P = 1/2^+$. The quantum numbers have not yet been measured, and our theoretical mass is in good agreement with the experimental mass and our theoretical width is in good agreement with the experimental width. We find a similar situation in the case of $\Sigma_c(2520)$, which is identified as a ground state with a spin excitation $J^P = 3/2^+$. The quantum numbers have not yet been measured, but

TABLE VI: As Table [IV] but for \( \Xi'c(snc) \) resonances.

Our theoretical mass is in good agreement with the experimental data, and the decay width is well reproduced. \( \Sigma_c(2800) \) is identified as the first \( P_3 \) wave excitation, with the assignment \( J^P = 1/2^- \); the theoretical mass and width are compatible with the experimental data.

3. \( \Xi'_c \) and \( \Xi_c \)

Our results for \( \Xi'_c \) resonances are reported in Table [VI] and those for \( \Xi_c \) are reported in Table [VII]. The \( \Xi'_c \) states belong to the sextet configuration and the \( \Xi_c \) states belong to the anti-3-plet. Identifying the available data for these states is more complex, since there are several theoretical excited states for \( \Xi'_c \) and \( \Xi_c \) in the same energy region. Additionally, for these states some experimental data are puzzling, as Ref. [8] reports a state with a central mass close to 2965 MeV. Hence, further studies are required in order to establish whether this narrow resonance is a different baryon from the narrow resonance at 2970 MeV found by Belle [8]. Moreover, the Belle collaboration recently measured the quantum numbers of \( \Xi'_c(2970) \) to be \( J^P = 1/2^+ \) [11], which could indicate a radial excitation. The observed masses of the ground states \( \Xi'_c \) and \( \Xi_c \) are well reproduced in our model, and are identified as \( J^P = 1/2^+ \) of the sextet and anti-3-plet,

**Notes:**
- All predicted masses are in MeV.
- The experimental errors are not provided in the table.
- The $\Gamma_{tot}$ and $\Gamma$ values are also in MeV.
- (*) indicates a predicted state that is in agreement with experiment.

**Discussion:**
- The $\Xi_c(2645)$ is identified as the $J^P = 3/2^+$ member of the sextet. In our model, its mass is well reproduced, and the width is underestimated. The states $\Xi_c(2790)$ and $\Xi_c(2815)$ are identified as $J^P = 1/2^-$ and $J^P = 3/2^-$, respectively, see Table VIII, these quantum numbers, which have not yet been measured, refer to the first orbital excitation of the anti-3-plet states. $\Xi_c(2923)$ is identified as the $P_3$-wave excitation $J^P = 1/2^-$ with spin $S = 3/2$ that belongs to the sextet; the theoretical width is compatible with the experimental value. Our assignment of $\Xi_c(2930)$ is to the $P_3$-wave $J^P = 3/2^-$ state with $S = 1/2$ that belongs to the sextet; our theoretical mass deviates by 5 MeV, but our theoretical width is in good agreement with the experimental value. Moreover, there is another possible assignment, as the $J^P = 1/2^-$ state with $S = 1/2$ is close in mass, and belongs to the anti-3-plet; only future experiments will determine the correct assignment.

Furthermore, there is a puzzle regarding the state observed by LHCb: it has not been established whether the $\Xi_c^0(2965)$ state is the isospin partner of $\Xi_c^+ (2970)$, or a different state. The complexity of identifying $\Xi_c(2965)$ is revealed by the fact that our model predicts two states, which adapt equally well for this state. The first $\Xi_c(2965)$ assignment is $J^P = 3/2^-$ with $S = 3/2$; this belongs to the sextet, and refers to a $P_3$-wave excitation. The experimental mass and the width are well reproduced. A second identification of $\Xi_c(2965)$ is a $P_0$-wave $J^P = 1/2^-$ state with $S = 3/2$; thus, $\Xi_c(2965)$ would belong to the anti-3-plet, since we obtain a similar mass of 2978 ± 6 MeV and width that is compatible with the experimental value. It is noteworthy that, if the experiments confirm that there is a $\Xi_c$ state at 2965 MeV which it is not a Roper state, it would mean that we could iden-

**TABLE VIII:** As Table [LV] but for \( \Lambda_c \) (nnc) resonances.

The authors identify this state as a member of the sextet or anti-\( 3\)-plet: either as a \( P_\lambda \)-wave excitation or as a \( P_\rho \)-wave excitation. The latter would imply that the charmed baryons behave as three-quark systems, instead of quark-diquark systems. Future experiments will help disentangle this puzzle. There is a similar situation for \( \Xi_c(3055) \), where we also have two possible assignments. The first one is its identification as the first \( P_\rho \)-wave state in the sextet, with \( J^P = 1/2^- \) and \( S = 1/2 \). Our theoretical mass exhibits a deviation of only 6 MeV, but the width is overestimated. The other possible \( \Xi_c(3055) \) assignment is to the \( P_\rho \)-wave state in the anti-\( 3\)-plet, with \( J^P = 5/2^- \) and \( S = 3/2 \). Here, the mass is well reproduced and the width is overestimated. \( \Xi_c(3080) \) is identified as the \( P_\rho \)-wave of the sextet, with \( J^P = 1/2^- \) and \( S = 3/2 \). While our theoretical mass is well reproduced, our width is overestimated. Finally, \( \Xi_c(3123) \) is identified as the first \( D_\lambda \)-wave excitation with \( J^P = 3/2^+ \) and is well reproduced.

4. \( \Lambda_c \)

Our results for \( \Lambda_c \) baryons are reported in Table [VIII]. The \( \Lambda_c^+ \) is identified as the ground state \( J^P = 1/2^+ \), with \( S = 1/2 \); its mass is well reproduced, with a small deviation of 15 MeV. For the excited states, we can observe a systematic deviation that exhibits the failure of the h.o. potential for these states. Nevertheless, the patterns in the theoretical mass spectrum can describe the experimental one. \( \Lambda_c(2595)^+ \) and \( \Lambda_c(2625)^+ \) are identified as our two \( P_\lambda \)-wave excitations \( J^P = 1/2^- \) and \( J^P = 3/2^- \), respectively, both with \( S = 1/2 \); their
masses are reproduced with a deviation of 15 MeV. The theoretical width is compatible with the experimental for \( \Lambda_c(2595)^+ \) states value but overestimated for \( \Lambda_c(2625)^+ \). If the \( \Lambda_c(2765)^* \) or \( \Sigma_c(2765) \) state is identified as the \( \Lambda_c \) state in our model, there is no resonance within this energy region. Although it is close in energy to our predicted state \( \Lambda_c(2800)^+ \), \( \Lambda_c(2765)^+ \) is expected to be a Roper-like resonance. Consequently, we fail to reproduce the \( \Lambda_c(2765)^+ \) mass in our model, since our first theoretical radial excitation is the \( \Lambda_c(3007)^+ \) state. The observed \( \Lambda_c(2860)^+ \) is identified with our state 3/2+, having a significant predicted mass deviation of 100 MeV, but the theoretical decay width is well reproduced. Finally, the observed \( \Lambda_c(2880)^+ \) is identified with our state 5/2+. In this case, we also have a predicted mass with a deviation of 100 MeV, and a large deviation of the decay width.

V. COMPARISON BETWEEN THE THREE-QUARK AND QUARK-DIQUARK STRUCTURES

In the light baryon sector, the successful constituent quark model reproduces the baryon mass spectra by assuming that the constituent quarks have roughly the same mass. This implies that the two oscillators, \( \rho \)- and \( \lambda \)-, have the same frequency, \( \omega_\rho \approx \omega_\lambda \), meaning that the \( \lambda \) and \( \rho \) excitation states are degenerate in the mass spectrum. In the charm sector, we have a mass splitting between the \( \lambda \) and \( \rho \), which comes from \( \omega_\lambda - \omega_\rho \approx 122 \) MeV for \( \Omega_c \) baryons, \( \omega_\lambda - \omega_\rho \approx 147 \) MeV for \( \Xi'_c \) and \( \Xi_c \) baryons.
baryons, and $\omega_\lambda - \omega_\rho \simeq 183$ MeV for $\Sigma_c$ and $\Lambda_c$ baryons. Consequently, we may expect to find these states in future experiments. However, given that the $\rho$ states have not been observed, it seems that the charmed baryons can have a special internal structure which corresponds to a quark-diquark configuration. The reduction of the effective degrees of freedom in the quark-diquark picture means fewer predicted states. We notice that, in the case of $\Lambda_c$ and $\Xi_c$ baryons, the number of states decreases drastically in the quark-diquark model, see Tables VIII and VII respectively. The lack of experimental data prevents us from reaching a decisive conclusion as to which description is better.

For instance, for the $\Omega_c$ baryons, we have identified all five $P_\lambda$-wave excited states, all with negative parity. We also expect two additional theoretical $\Omega_c(3129)$, $J = 1/2^-$ and $\Omega_c(3156)$, $J = 3/2^-$ states with negative parity. The existence of these states may indicate that the charmed baryons are not quark-diquark systems.

VI. CONCLUSIONS

We have calculated the mass spectra, strong partial decay widths and total decay widths of charmed baryons up to the $D$-wave shell for all the possible decay channels which respect quantum number conservation. All charmed baryons are simultaneously described by a global fit in which the same set of model parameters predicts the charm-baryon masses and strong partial decay widths in all the possible decay channels up to the $D$-wave shell. Moreover, the charm-baryon mass spectra are given in both the three-quark and the quark-diquark schemes. Propagation of the parameter uncertainties via a Monte Carlo bootstrap method is also included. This is often missing in theoretical papers on this subject. Nevertheless, it is necessary in order to guarantee a rigorous treatment of the uncertainties in the predicted mass spectra and decay widths. Our mass and strong partial decay width predictions are in good agreement with the available experimental data, and show the ability to guide future experimental searches by LHCb, Belle and Belle II. Moreover, for all the possible decay channels, we provide the flavor coupling coefficients, which are relevant to further theoretical investigations on charm-baryon strong decay widths. To the best of our knowledge, considering that the calculations of the strong decay widths are barely sensitive to the specific model used, our strong partial decay width predictions constitute the most complete calculation in the charm-baryon sector to date.

Appendix A: Baryon wave functions

1. The harmonic oscillator wave functions

In the heavy-light sector, the the pseudo- and lambda-modes decouple; therefore, they can be distinguished through an analysis of the heavy-light baryon mass spectra. This is because there is a difference in frequency between the pseudo- and lambda-modes,

\[ \omega_p = \sqrt{\frac{3K_Q}{m_p}} \quad \text{and} \quad \omega_\lambda = \sqrt{\frac{3K_Q}{m_\lambda}}, \tag{A1} \]

where \( m_p \) and \( m_\lambda \) are defined in Section 11B. We write the baryon wave functions in terms of \( \omega_p \) and \( \omega_\lambda \) by using the relation \( \alpha_{p,\lambda}^2 = \omega_p \omega_\lambda m_p m_\lambda \).

Also, we use the standard Jacobi coordinates:

\[
\begin{align*}
\mathbf{p}_p &= \frac{1}{2}(\mathbf{p}_1 - \mathbf{p}_2), \\
\mathbf{p}_\lambda &= \frac{1}{3}(\mathbf{p}_1 + \mathbf{p}_2 - 2\mathbf{p}_3), \\
\mathbf{p}_{cm} &= \mathbf{p}_1 + \mathbf{p}_2 + \mathbf{p}_3, \tag{A2}
\end{align*}
\]

for the baryon, and

\[
\mathbf{q}_c = \frac{1}{2}(\mathbf{p}_3 - \mathbf{p}_5), \tag{A3}
\]

for the meson. In this coordinate system, \( \mathbf{p}_3 \) refers to the charm quark and \( \mathbf{p}_{1,2} \) to the light quarks. Finally, \( \mathbf{p}_5 \) is the anti-quark momentum.

For the S-wave charmed baryon, we have,

\[
\psi(0, 0, 0) = 3^{3/4} \left( \frac{1}{\pi \omega_p m_p} \right)^{1/2} \left( \frac{1}{\pi \omega_\lambda m_\lambda} \right)^{1/2} \times \exp \left[ -\frac{\mathbf{p}_p^2}{2\omega_p m_p} - \frac{\mathbf{p}_\lambda^2}{2\omega_\lambda m_\lambda} \right]. \tag{A4}
\]

For the P-wave charmed baryon, we have,

\[
\begin{align*}
\psi(1, m, 0, 0) &= -i 3^{3/4} \left( \frac{8}{3\sqrt{\pi}} \right)^{1/2} \left( \frac{1}{\omega_p m_p} \right)^{5/4} Y_1^m(p) \\
&\times \left( \frac{1}{\pi \omega_\lambda m_\lambda} \right)^{3/4} \exp \left[ -\frac{\mathbf{p}_p^2}{2\omega_p m_p} - \frac{\mathbf{p}_\lambda^2}{2\omega_\lambda m_\lambda} \right]. \tag{A5}
\end{align*}
\]

For the D-wave charmed baryon, we have,

\[
\begin{align*}
\psi(2, m, 0, 0) &= 3^{3/4} \left( \frac{16}{15\sqrt{\pi}} \right)^{1/2} \left( \frac{1}{\omega_p m_p} \right)^{7/4} Y_2^m(p) \\
&\times \left( \frac{1}{\pi \omega_\lambda m_\lambda} \right)^{3/4} \exp \left[ -\frac{\mathbf{p}_p^2}{2\omega_p m_p} - \frac{\mathbf{p}_\lambda^2}{2\omega_\lambda m_\lambda} \right]. \tag{A7}
\end{align*}
\]

For the D-wave charmed baryon, we have,

\[
\begin{align*}
\psi(1, m, 1, m') &= -3^{3/4} \left( \frac{8}{3\sqrt{\pi}} \right)^{1/2} \left( \frac{1}{\omega_p m_p} \right)^{5/4} Y_1^m(p) \\
&\times \left( \frac{8}{3\sqrt{\pi}} \right)^{1/2} \left( \frac{1}{\omega_p m_p} \right)^{5/4} Y_1^{m'}(p) \\
&\times \exp \left[ -\frac{\mathbf{p}_p^2}{2\omega_p m_p} - \frac{\mathbf{p}_\lambda^2}{2\omega_\lambda m_\lambda} \right]. \tag{A9}
\end{align*}
\]

Here \( Y_1^m(p) \) is the solid harmonic polynomial. The wave function of the first radially excited charmed baryon \( \psi(k_\lambda, k_p) \) reads as

\[
\begin{align*}
\psi(1, 0) &= 3^{3/4} \left( \frac{2}{3} \right)^{1/2} \left( \frac{1}{\pi \omega_p m_p \omega_\lambda m_\lambda} \right)^{3/4} \left[ \frac{3}{2} \frac{\mathbf{p}_5^2}{\omega_\lambda m_\lambda} \right] \\
&\times \exp \left[ -\frac{\mathbf{p}_p^2}{2\omega_p m_p} - \frac{\mathbf{p}_\lambda^2}{2\omega_\lambda m_\lambda} \right]. \tag{A10}
\end{align*}
\]

The ground state wave function of the meson is

\[
\psi(0, 0) = \left( \frac{R^2}{\pi} \right)^{3/4} \exp \left[ -\frac{R^2 (\mathbf{p}_3 - \mathbf{p}_5)^2}{8} \right]. \tag{A12}
\]
Appendix B: Flavor wave functions of charmed baryons

In the charm sector, we consider the 6-plet and the 3-plet representation of the flavor wave functions. In the following subsections, we give the flavor wave functions of a charmed baryon $A_c$ and its isospin quantum numbers $|I_c, M_I, M_f\rangle$.

a. 6-plet

\[
|\Omega_{c, 0, 0} \rangle : = |ssc\rangle \hspace{1cm} (B1)
\]
\[
|\Xi_{c, 0}^{0}, 1/2, -1/2 \rangle : = \frac{1}{\sqrt{2}}(|dsc\rangle + |sdc\rangle) \hspace{1cm} (B2)
\]
\[
|\Xi_{c, 0}^{+}, 1/2, 1/2 \rangle : = \frac{1}{\sqrt{2}}(|usc\rangle + |suc\rangle) \hspace{1cm} (B3)
\]
\[
|\Sigma_{c, 0}^{+}, 1, 1 \rangle : = |wuc\rangle \hspace{1cm} (B4)
\]
\[
|\Sigma_{c, 1}^{+}, 1, 0 \rangle : = \frac{1}{\sqrt{2}}(|udc\rangle + |duc\rangle) \hspace{1cm} (B5)
\]
\[
|\Sigma_{c, 2}^{+}, 1, 0 \rangle : = \frac{1}{\sqrt{2}}(|udc\rangle - |duc\rangle) \hspace{1cm} (B6)
\]

b. 3-plet

\[
|\Xi_{c, 0}^{0}, 1/2, -1/2 \rangle : = \frac{1}{\sqrt{2}}(|dsc\rangle - |sdc\rangle) \hspace{1cm} (B7)
\]
\[
|\Xi_{c, 0}^{+}, 1/2, 1/2 \rangle : = \frac{1}{\sqrt{2}}(|usc\rangle - |suc\rangle) \hspace{1cm} (B8)
\]
\[
|\Lambda_{c, 0}^{+}, 0, 0 \rangle : = \frac{1}{\sqrt{2}}(|udc\rangle - |duc\rangle) \hspace{1cm} (B9)
\]

Appendix C: Light-baryon wave functions

Whenever our final states contained a light baryon, we have used the following conventions, considering the $S_3$ invariant space-spin-flavor ($\Psi = \psi \chi \phi$). Thus, the light-baryon wave functions are given by

\[2^8[56, L^p] : \psi_S(\chi_p \phi_p + \chi \phi_s)/\sqrt{2}, \]
\[2^8[70, L^p] : [\psi_p(\chi_p \phi_s + \chi \phi_p) + \psi_s(\chi_p \phi_p - \chi \phi_s)]/2, \]
\[4^8[70, L^p] : (\psi_p \phi_p + \psi_s \phi_s) \chi_s/\sqrt{2}, \]
\[2^8[20, L^p] : \psi_A(\chi_p \phi_s - \chi \phi_p)/\sqrt{2}, \]
\[4^10[56, L^p] : \psi_S \chi S \phi_S, \]
\[2^10[70, L^p] : (\psi_p \chi_p + \psi_s \chi_s) \phi_S/\sqrt{2}, \]
\[2^10[70, L^p] : (\psi_p \chi - \psi_s \chi_p) \phi_A/\sqrt{2}, \]
\[4^10[20, L^p] : \psi_A \chi S \phi_A. \hspace{1cm} (C1)\]

The quark orbital angular momentum $L$ is coupled with the spin $S$ to yield the total angular momentum $J$ of the baryon.

1. Flavor wave functions of light baryons

For the flavor wave functions $|I, M_I, M_f, Y\rangle$ we adopt the convention of Ref. 69 with $(p, q) = (g_1 - g_2, g_2)$.

- The octet baryons

\[|(1, 1), \frac{1}{2}, \frac{1}{2} \rangle : \phi_\rho(\Lambda) = \frac{1}{\sqrt{3}}[|udu\rangle - |duu\rangle] \hspace{1cm} (C2)\]
\[\phi_\lambda(\Lambda) = \frac{1}{\sqrt{6}}[2|udu\rangle - |udu\rangle] \]
\[|(1, 1), 1, 1 \rangle : \phi_\rho(\Sigma^+) = \frac{1}{\sqrt{2}}[|usu\rangle - |sus\rangle] \hspace{1cm} (C3)\]
\[\phi_\lambda(\Sigma^+) = \frac{1}{\sqrt{6}}[2|usu\rangle + |sus\rangle] \]
\[|(1, 1), 0, 0 \rangle : \phi_\rho(\Xi^0) = \frac{1}{\sqrt{2}}[|usu\rangle - |sus\rangle] \hspace{1cm} (C4)\]
\[\phi_\lambda(\Xi^0) = \frac{1}{\sqrt{6}}[2|usu\rangle - |sus\rangle] \]

- The decuplet baryons

\[|(3, 0), \frac{3}{2}, \frac{3}{2}, 1 \rangle : \phi_S(\Delta^{++}) = |uuu\rangle \hspace{1cm} (C6)\]
\[|(3, 0), 1, 1 \rangle : \phi_S(\Sigma^+) = \frac{1}{\sqrt{3}}[|usu\rangle + |sus\rangle + |uss\rangle] \hspace{1cm} (C7)\]
\[|(3, 0), \frac{1}{2}, \frac{1}{2}, -1 \rangle : \phi_S(\Xi^0) = \frac{1}{\sqrt{2}}[|usu\rangle + |sus\rangle + |uss\rangle] \hspace{1cm} (C8)\]
\[|(3, 0), 0, 0, -2 \rangle : \phi_S(\Omega^-) = |ss\rangle \hspace{1cm} (C9)\]

- The singlet baryons

\[|(0, 0), 0, 0 \rangle : \phi_A(\Lambda) = \frac{1}{\sqrt{6}}[|uds\rangle - |dus\rangle + |dsu\rangle - |sdu\rangle + |sud\rangle - |uds\rangle] \hspace{1cm} (C10)\]
Appendix D: Flavor wave functions of mesons

In the following subsections, we give the flavor wave functions of a meson $C$ and its isospin quantum numbers $(I, M_I)$.

1. Pseudoscalar mesons

Since the mixing angle $\theta_{\eta\eta'}$ between $\eta$ and $\eta'$ is small, we set $\theta_{\eta\eta'} = 0$. Thus, we identify $\eta = \eta_8$ and $\eta' = \eta_1$.

- The octet mesons
  \[
  |\pi^+, 1, 1\rangle = -|ud\rangle \\
  |\pi^0, 1, 0\rangle = \frac{1}{\sqrt{2}}(|u\bar{u}| - |d\bar{d}|) \\
  |\pi^-, 1, -1\rangle = |d\bar{u}\rangle \\
  |\pi^+, 1/2, 1/2\rangle = -|u\bar{s}\rangle \\
  |\pi^-, 1/2, -1/2\rangle = |s\bar{u}\rangle \\
  |\eta, 0, 0\rangle = \frac{1}{\sqrt{6}}(|u\bar{u}| + |d\bar{d}| - 2|s\bar{s}|) 
  \]

- The singlet mesons
  \[
  |\eta', 0, 0\rangle = \frac{1}{\sqrt{3}}(|u\bar{u}| + |d\bar{d}| + |s\bar{s}|) 
  \]

2. Vector Mesons

We consider that the $\phi$ meson is a pure $s\bar{s}$ state; thus, we have the following wave functions:

- The octet mesons
  \[
  |\rho^+, 1, 1\rangle = -|ud\rangle \\
  |\rho^0, 1, 0\rangle = \frac{1}{\sqrt{2}}(|u\bar{u}| - |d\bar{d}|) \\
  |\rho^-, 1, -1\rangle = |d\bar{u}\rangle \\
  |\rho^+, 1/2, 1/2\rangle = -|u\bar{s}\rangle \\
  |\rho^-, 1/2, -1/2\rangle = |s\bar{u}\rangle \\
  |\omega, 0, 0\rangle = \frac{1}{\sqrt{2}}(|u\bar{u}| + |d\bar{d}|) 
  \]

- The singlet mesons
  \[
  |\phi, 0, 0\rangle = |s\bar{s}\rangle 
  \]

3. Charmed Mesons

In the case of charmed-$D$ mesons, the flavor wave functions are the same for the pseudoscalar and vector states. We use the following flavor wave functions:

\[
|D_1^{+, 0, 0}\rangle = |D_8^+ 0, 0\rangle = |c\bar{s}\rangle \\
|D_1^{+, 1/2, 1/2}\rangle = |D_8^0 1/2, 1/2\rangle = |c\bar{d}\rangle \\
|D_1^{0, 1/2, -1/2}\rangle = |D_8^0 1/2, -1/2\rangle = |c\bar{u}\rangle 
\]

Appendix E: Flavor coupling

In the following subsections, we give the flavor coefficients $F_{ABC}$ used to calculate the transition amplitudes. We compute $F_{ABC} = \langle \phi_B \phi_C | \phi_A \rangle$ where $\phi_{A,B,C}$ refers to the initial flavor wave function of a charmed baryon $\phi_A$, final baryon $\phi_B$, and final meson $\phi_C$, respectively; $\phi_0^5 = (u\bar{u} + d\bar{d} + s\bar{s})/\sqrt{3}$ is the flavor singlet-wave function of SU(3). In addition, we compute the flavor decay coefficients of the isospin channels, since we assume that the isospin symmetry holds even though it is slightly broken. The corresponding charge channels are obtained by multiplying our $F_{A\to BC}$ by the corresponding Clebsch-Gordan coefficient in the isospin space.

C1 and C2 Thus, the flavor charge channel for a specific projection $(I, M_I)$ in the isospin channel is obtained as follows:

\[
F_A(I_A, M_{I_A})\to B(I_B, M_{I_B})C(I_C, M_{I_C}) = \langle \phi_B, I_B, M_{I_B}, \phi_C, I_C, M_{I_C} | \phi_0, 0, 0, \phi_A, I_A, M_{I_A} \rangle_F \\
= \langle I_B, M_{I_B}, I_C, M_{I_C} | I_A, M_{I_A} F_{A\to BC} \rangle 
\]

where $\langle I_B, M_{I_B}, I_C, M_{I_C} | I_A, M_{I_A} \rangle$ is a Clebsch-Gordan coefficient and the flavor functions $\phi_i$ of each baryon and meson have a specific isospin projection $M_I$.

1. charmed baryons and pseudoscalar mesons

We give the squared flavor-coupling coefficients, $F_{A\to BC}^2$, when the final states have a pseudoscalar light meson. Here, $A$ and $B$ are charmed baryons, and the subindexes 6f and 3f refer to the sextet and the anti-triplet baryon multiplets. The $C$ is a pseudoscalar meson and the subindexes 8 and 1 refer to the octet and singlet meson multiplets, respectively.

\[
A_{6_f} \to B_{6_f} + C_8 
\]
\[
\begin{pmatrix}
\Omega_c \\
\Sigma_c \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Xi_c' K \\
\Sigma_c \pi \\
\Sigma_c \pi
\end{pmatrix}
\]
\[
= \begin{pmatrix}
\frac{1}{3} \\
\frac{1}{6} \\
\frac{1}{12} \frac{1}{8} \frac{1}{72}
\end{pmatrix}
\]  

\[A_{8_i} \rightarrow B_{6_i} + C_1 \]

\[
\begin{pmatrix}
\Omega_c' \\
\Sigma_c' \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Xi_c' K \\
\Sigma_c' \pi \\
\Sigma_c' \pi
\end{pmatrix}
\]
\[
= \begin{pmatrix}
\frac{1}{3} \\
\frac{1}{6} \\
\frac{1}{12} \frac{1}{8} \frac{1}{72}
\end{pmatrix}
\]

\[A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[
\begin{pmatrix}
\Lambda_c \\
\Xi_c \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Xi_c' K^* \\
\Sigma_c' K^* \\
\Sigma_c' K^*
\end{pmatrix}
\]
\[
= \begin{pmatrix}
\frac{1}{6} \frac{1}{9} \frac{1}{27}
\end{pmatrix}
\]

\[A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[
\begin{pmatrix}
\Omega_c \\
\Sigma_c \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Xi_c' K^* \\
\Sigma_c' K^* \\
\Sigma_c' K^*
\end{pmatrix}
\]
\[
= \begin{pmatrix}
\frac{1}{6} \frac{1}{9} \frac{1}{27}
\end{pmatrix}
\]

\[A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[
\begin{pmatrix}
\Omega_c \\
\Sigma_c \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Omega_c' \phi \\
\Sigma_c' \phi \\
\Xi'_c \phi
\end{pmatrix}
\]
\[
= \begin{pmatrix}
\frac{1}{5} \frac{1}{9} \frac{1}{27}
\end{pmatrix}
\]

\[A_{8_i} \rightarrow B_{6_i} + C_1 \]

\[\Xi_c' \rightarrow \Xi_c' \eta' = \frac{1}{9} \]  

\[A_{8_i} \rightarrow B_{6_i} + C_1 \]

\[\Xi_c' \rightarrow \Xi_c' \eta' = \frac{1}{9} \]  

\[E_2 \]

\[E_3 \]

\[E_4 \]

\[E_5 \]

\[E_6 \]

\[E_7 \]

\[E_8 \]

\[E_9 \]

\[E_{10} \]

\[E_{11} \]

2. Charmed baryons and vector mesons

We give the squared flavor-coupling coefficients, \( F_{8\rightarrow BC}^2 \), when the final states have a vector-light meson. Here \( A \) and \( B \) are charmed baryons, and the subindexes \( 6_i \) and \( 3_i \) refer to the sextet and the anti-triplet baryon multiplets. The \( C \) is a vector meson and the subindexes \( 8 \) and \( 1 \) refer to the octet and singlet meson multiplets respectively.

\[ A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[ A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[ A_{8_i} \rightarrow B_{6_i} + C_8 \]

\[ A_{8_i} \rightarrow B_{6_i} + C_1 \]
• $A_{6t} \rightarrow B_{3i} + C_8$

\[
\begin{pmatrix}
\Omega_c \\
\Sigma_c \\
\Xi'_c
\end{pmatrix}
\rightarrow
\begin{pmatrix}
\Xi_c K^* \\
\Lambda_c \rho \\
\Xi_c \rho \\
\Xi_c \omega
\end{pmatrix}
= 
\begin{pmatrix}
1/6 \\
1/3 \\
1/12 \\
1/8 \\
1/24
\end{pmatrix}
\tag{E12}
\]

• $A_{6t} \rightarrow B_{3i} + C_1$

\[ (\Xi'_c) \rightarrow (\Xi_c \phi) = \left( \frac{1}{12} \right) \]  (E13)

3. Light baryons and charm-(pseudoscalar/vector) mesons

We give the $F^2_{A\rightarrow BC}$ when the final states have a light baryon and a charm-(pseudoscalar/vector) meson. Since the mesons $D^0$ and $D^+$ form an isospin doublet, both are treated as $D$ in the tables; whereas $D_s$ is separated by the strangeness content. The subindexes $6_t$ and $3_t$ refer to the sextet and the anti-triplet baryon multiplets for the initial charmed baryon $A$, whereas the final $B$ baryons can have subindexes $8$ or $10$, according to whether the final light baryon belongs to the octet or decuplet baryon multiplets. Additionally, owing to the symmetry of the wave functions of the octet-light baryons, see \[\text{[X]}\] we can have only $\rho$ or $\lambda$ contributions in the final states, as indicated by a superindex.

• $A_{6t} \rightarrow B_{10} + C$

\[ (\Omega_C) \rightarrow \left( \begin{array}{c}
\Xi_{10} D \\
\Omega_{10} D_s
\end{array} \right) = \left( \begin{array}{c}
3/4 \\
1/4
\end{array} \right) \]  (E18)

\[ (\Sigma_c) \rightarrow \left( \begin{array}{c}
\Delta D \\
\Sigma_{10} D_s
\end{array} \right) = \left( \begin{array}{c}
4/9 \\
1/9
\end{array} \right) \]  (E19)

• $A_{6t} \rightarrow B_8 + C$

\[ (\Omega_C) \rightarrow \left( \begin{array}{c}
\Xi_8 D \\
\Sigma_{10} D_s
\end{array} \right) = \left( \begin{array}{c}
4/9 \\
1/9
\end{array} \right) \]  (E20)

Appendix F: Partial decay widths

The partial-decay widths, $\Gamma_{A\rightarrow BC}$, of an initial baryon $A$ decaying to a final baryon $B$ plus a meson $C$, in all the open-flavor channels, are shown in Tables \[\text{[XX]}\] \[\text{[XIII]}\] Here, we give the contribution of the isospin channels. The charge channel width for baryon $A$ with isospin projection $I_A$ and $M_{I_A}$ can be obtained as follows

\[ \Gamma_{A(I_A, M_{I_A}) \rightarrow B | I_B, M_{I_B} > C | I_C, M_{I_C})} = \langle I_B, M_{I_B}, I_C, M_{I_C} | I_A, M_{I_A} \rangle^2 \Gamma_{A \rightarrow BC} \]  (F1)
where $\langle I_R, M_{I_R}, I_C, M_{I_C}, I_A, M_{I_A} \rangle$ is a Clebsch-Gordan coefficient, and the partial decay width $\Gamma_{A \rightarrow BC}$ can be extracted from Tables IX-XIII.

TABLE IX: Partial decay widths for $\Omega_c^{(sc)}$; the values are given in MeV. The partial decay widths are computed by means of Eq. 7. The states are labeled with the spectroscopic notation $^2S_{+1/2}L_{J}$, which is characterized by total angular momentum $J = L + S_{tot}$, where $S_{tot} = S_\rho + \frac{1}{2}$, and $L = l_\rho + l_\lambda$. The order of the states is the same as is presented in Table IV.
