

ON EXTENDABILITY OF FUNCTIONALS ON HILBERT  $C^*$ -MODULES

V. MANUILOV

ABSTRACT. Let  $M \subset N$  be Hilbert  $C^*$ -modules over a  $C^*$ -algebra  $A$  with  $M^\perp = 0$ . It was shown recently by J. Kaad and M. Skeide that there exists a non-zero  $A$ -valued functional on  $N$  such that its restriction onto  $M$  is zero. Here we show that this may happen even if  $A$  is monotone complete. On the other hand, we show that for certain type I  $W^*$ -algebras this cannot happen.

## 1. INTRODUCTION

Hilbert  $C^*$ -modules were introduced by W. Paschke in [8] and became a useful tool in various aspects of noncommutative geometry and topology. The idea behind this notion is to generalize the notion of a Hilbert space by replacing the field of the complex numbers, both as scalars and as the range for the inner product, by a  $C^*$ -algebra  $A$ . For details about Hilbert  $C^*$ -modules we refer to [4, 6, 7]. In some aspects, Hilbert  $C^*$ -modules behave like Hilbert spaces, but there are three major differences.

First, while any element  $m \in M$  of a Hilbert  $C^*$ -module  $M$  determines an  $A$ -antilinear map  $x \mapsto \langle x, m \rangle = \widehat{m}(x)$ ,  $\widehat{m} : M \rightarrow A$ , not any bounded  $A$ -antilinear map from  $M$  to  $A$  is of this form, i.e. there is no Riesz theorem. The  $A$ -module of all bounded  $A$ -antilinear maps is called the dual module and is denoted by  $M'$ . The map  $m \mapsto \widehat{m}$  determines an isometric inclusion  $M \subset M'$ , which is often not surjective. As a corollary, bounded  $A$ -linear operators on Hilbert  $C^*$ -modules need not have an adjoint. This explains the interest in special classes of Hilbert  $C^*$ -modules like self-dual or reflexive ones.

The dual module  $M'$  often has no Hilbert  $C^*$ -module structure. Nevertheless, when the underlying  $C^*$ -algebra  $A$  is a  $W^*$ -algebra, or, slightly more generally, a monotone complete  $C^*$ -algebra, the inner product  $\langle \cdot, \cdot \rangle$  extends from  $M$  to  $M'$  in a natural way, [2].

Second, while there is only one (up to an isometric isomorphism) separable Hilbert space  $l_2(\mathbb{C})$ , a countably generated Hilbert  $C^*$ -module over  $A$  need not be isometrically isomorphic to the standard Hilbert  $C^*$ -module  $l_2(A)$ .

Third, a Hilbert  $C^*$ -submodule  $M \subset N$  in a Hilbert  $C^*$ -module  $N$  need not be (orthogonally) complementable. It may easily happen that the orthogonal complement  $M^\perp$  is zero, while  $M$  is strictly smaller than  $N$ . We call such submodules *thick*.

Any element  $n \in N$  determines a functional  $\widehat{n}|_M$  on  $M$  given by  $\widehat{n}|_M(m) = \langle m, n \rangle$ . A long-standing problem was to check whether the norms  $\|n\|$  and  $\|\widehat{n}|_M\|$  coincide. If  $A$  is a  $W^*$ -algebra and if  $N = M'$  (in this case  $M'$  is a Hilbert  $C^*$ -module) then it was shown in [8] that these two norms are the same.

Recently, a surprising counterexample appeared in [3], showing that for  $A = C[0; 1]$  and for  $M = l_2(A)$ , there exists  $N$  such that  $M$  is thick in  $N$ , and the two norms differ. As

a consequence, it was shown in [3] that there exist non-zero functionals on  $N$  with zero restriction onto  $M$ , thus showing that thick submodules may be not so thick.

Hilbert  $C^*$ -modules over  $C[0, 1]$  are reflexive, i.e. the second dual module  $M''$  coincides with  $M$ , but the first dual module is not a Hilbert one, which is a reason behind a lot of counterexamples. In this paper, we focus on the class of Hilbert  $C^*$ -modules, for which  $M' = M''$  is a Hilbert  $C^*$ -module. In particular, this is the case when  $A$  is a monotone complete  $C^*$ -algebra [2].

We show that even when  $A$  is monotone complete, the two norms may be different. On the other hand, we show that if  $A = L^\infty(X)$  is a commutative  $W^*$ -algebra or  $A = \mathbb{B}(H)$  is the algebra of all bounded operators on a Hilbert space then the two norms coincide. We have no idea on what happens when  $A$  is a general  $W^*$ -algebra.

In order to compare the norms, we associate to each element  $f$  of the dual module, a right ideal  $J_f$  in  $A$  and show that the size of this ideal is related to the coincidence of the two norms.

The author is grateful to M. Frank and E. Troitsky for fruitful discussions.

## 2. HILBERT $C^*$ -MODULES WITH HILBERT DUAL

Recall that the map  $m \mapsto \widehat{m}$ ,  $M \rightarrow M'$ , defines an isometric inclusion, so we may identify  $M$  with a subset in  $M'$  via this map.

**Definition 1.** *A Hilbert  $C^*$ -module  $M$  over a  $C^*$ -algebra  $A$  is called a module with a Hilbert dual if the inner product  $\langle \cdot, \cdot \rangle$  on  $M$  extends to an inner product  $\langle \cdot, \cdot \rangle'$  on  $M'$  such that  $\langle \widehat{m}, \widehat{n} \rangle' = \langle m, n \rangle$  and  $f(m) = \langle \widehat{m}, f \rangle'$  for any  $m, n \in M$  and any  $f \in M'$ .*

**Lemma 2.** *Let  $M$  be a Hilbert  $C^*$ -module with a Hilbert dual. Then  $M'$  is self-dual.*

*Proof.* The identity map extends to the inclusion  $M'' \subset M'$  for any Hilbert  $C^*$ -module. If  $M'$  is a Hilbert  $C^*$ -module then the identity map extends to the inclusion  $M' \subset M''$ . Hence  $M'' = M'$ . □

**Proposition 3.** *Let  $\langle \cdot, \cdot \rangle'$  and  $\langle \cdot, \cdot \rangle''$  be two such extensions of the inner product on  $M$  to inner products on  $M'$ . Then they coincide.*

*Proof.* Set  $\langle f, g \rangle^+ = \frac{1}{2}(\langle f, g \rangle' + \langle f, g \rangle'')$ ,  $f, g \in M'$ . Then  $\langle \cdot, \cdot \rangle^+$  is also an extension of the inner product on  $M$ . Then  $\langle f, f \rangle' \leq 2\langle f, f \rangle^+$  for any  $f \in M'$ , hence  $\text{id} : M' \rightarrow M'$  is a bounded map from  $(M', \langle \cdot, \cdot, \cdot \rangle^+)$  to  $(M', \langle \cdot, \cdot, \cdot \rangle')$ . It is also obviously  $A$ -linear.

As  $M'$  with any inner product is self-dual, there exists the adjoint operator  $\text{id}^* : (M', \langle \cdot, \cdot, \cdot \rangle') \rightarrow (M', \langle \cdot, \cdot, \cdot \rangle^+)$ . By definition,  $\langle \text{id} f, g \rangle' = \langle f, \text{id}^* g \rangle^+$  for any  $f, g \in M'$ . In particular, this holds for  $f = \widehat{m}$ ,  $m \in M$ . Then

$$\langle \text{id} \widehat{m}, g \rangle^+ = \langle \widehat{m}, g \rangle = \langle \widehat{m}, \text{id}^* g \rangle = \langle \widehat{m}, \text{id}^* g \rangle'$$

for any  $g \in M'$  and any  $m \in M$ , hence  $\text{id}^* g = \text{id} g$ , i.e.  $\text{id}^* = \text{id}$ , therefore  $\langle f, g \rangle' = \langle \text{id} f, \text{id} g \rangle^+$  for any  $f, g \in M'$ . Thus,  $\langle f, g \rangle' = \langle f, g \rangle''$  for any  $f, g \in M'$ . □

Any self-dual Hilbert  $C^*$ -module and any Hilbert  $C^*$ -module over a monotone complete  $C^*$ -algebra is obviously a module with a Hilbert dual [2].

## 3. RIGHT IDEALS FROM FUNCTIONALS

Let  $f \in M'$ . Define the subset  $J_f \subset A$  by  $J_f = \{a \in A : fa \in M\}$ .

**Lemma 4.**  $J_f$  is a closed right ideal in  $A$ .

*Proof.* Obvious. □

Apart from the trivial case when  $f \in M$  (then  $M_f = A$ ), there are two extreme cases for the right ideal  $J_f$  when  $f \notin M$ :

- $J_f$  is zero;
- $J_f$  is essential, i.e.  $aJ_f = 0$ ,  $a \in A$ , implies  $a = 0$ .

Let  $M$  be a Hilbert  $C^*$ -module over a  $C^*$ -algebra  $A$ ,  $f \in M'$ . Define  $M_f^0$  as the  $A$ -linear span of  $M$  and  $f$ , i.e.

$$M_f^0 = \{m + fa : m \in M, a \in A\} \subset M',$$

and let  $M_f$  be the norm closure of  $M_f^0$ . Usually,  $M_f$  need not be a pre-Hilbert  $C^*$ -module, i.e. the inner product on  $M$  need not be extendable to  $M_f$ , but sometimes this happens, e.g. when  $A$  is a monotone complete  $C^*$ -algebra [2]. We are interested in the uniqueness of the inner product extension from  $M$  to  $M_f$ , or to larger modules, e.g. to  $M'$ .

**Lemma 5.** *Suppose that the inner product on  $M$  extends to an inner product on  $M_f$ . If the right ideal  $J_f$  is essential then the extended inner product on  $M_f$  is unique.*

*Proof.* Let  $\langle \cdot, \cdot \rangle_1$  and  $\langle \cdot, \cdot \rangle_2$  be two extensions of the inner product  $\langle \cdot, \cdot \rangle$  on  $M$  making  $M_f$  a pre-Hilbert  $C^*$ -module. Set  $a_i = \langle f, f \rangle_i$ ,  $i = 1, 2$ . If  $j \in J_f$  then  $fj \in M$ , hence  $f(fj) = \langle fj, f \rangle_i$ ,  $i = 1, 2$ , hence  $j^*a_1 = j^*a_2$ , or, equivalently, passing to the adjoints,  $(a_2 - a_1)j = 0$ . As this holds for any  $j \in J_f$  and as  $J_f$  is essential then  $a_2 - a_1 = 0$ , hence the two inner products coincide. □

**Theorem 6.** *Suppose that  $M$  is a Hilbert  $C^*$ -module with a Hilbert dual, and let  $\langle \cdot, \cdot \rangle_{M'}$  be the extension of the inner product  $\langle \cdot, \cdot \rangle$  from  $M$  to  $M'$ . Suppose also that  $M$  is a thick submodule in a Hilbert  $C^*$ -module  $N$  with the inner product  $\langle \cdot, \cdot \rangle_N$ , which determines an injection  $i : N \rightarrow M'$  (the inner product on  $M$  is supposed to be the restriction of the inner product on  $N$ ). If the right ideal  $J_f$  is essential for any  $f \in M'$  then the inner product on  $N$  coincides with the extended inner product on  $M'$ , i.e.  $\langle n, n' \rangle_N = \langle i(n), i(n') \rangle_{M'}$  for any  $n, n' \in N$ .*

*Proof.* Recall that the injection  $i$  is defined as follows: for  $n \in N$ , set  $i(n)(m) = \langle m, n \rangle_N$ ,  $m \in M$ , i.e.  $i(n) = \widehat{n}|_M$ . Thickness of  $M$  in  $N$  implies that  $i$  is injective.

Suppose that there exists  $n \in N$  such that  $\langle n, n \rangle_N \neq \langle i(n), i(n) \rangle_{M'}$ . Set  $f = i(n) \in M'$ , and let  $j \in J_f$ . Then, by definition,  $m = i(n)j \in M$ , and

$$\langle m', nj \rangle_N = \langle m', nj \rangle_N = i(nj)(m') = \langle m', i(n)j \rangle_{M'}, \quad m' \in M$$

hence  $\langle m', nj - m \rangle_N = 0$  for any  $m' \in M$ . As  $M$  is thick in  $N$ , the latter implies that  $nj = m \in M$ .

Set  $a = \langle n, n \rangle_N$ ,  $b = \langle i(n), i(n) \rangle_{M'}$ . Then

$$j^*aj = \langle nj, nj \rangle_N = \langle m, m \rangle_M = \langle i(n)j, i(n)j \rangle_{M'} = j^*bj,$$

hence  $j^*(a - b)j = 0$  for any  $j \in J_f$ . As  $J_f$  is essential, this implies that  $a = b$ . Thus,  $\langle n, n \rangle_N = \langle i(n), i(n) \rangle_{M'}$  for any  $n \in N$ . Polarization identity then implies that  $\langle n', n \rangle_N = \langle i(n'), i(n) \rangle_{M'}$  for any  $n, n' \in N$ .  $\square$

**Theorem 7.** *Suppose that  $m$  is a Hilbert  $C^*$ -module with a Hilbert dual, and let  $\langle \cdot, \cdot \rangle'$  be the extension of the inner product  $\langle \cdot, \cdot \rangle$  from  $M$  to  $M'$ , hence to  $M_f \subset M'$ . Suppose also that  $\langle f, f \rangle' \geq 1$ . If  $J_f = 0$  then there exists a Hilbert  $C^*$ -module  $N$  such that  $M \subset N$  is thick,  $f \in N$ , and the norm of  $f$  as a functional (i.e. the standard norm on  $M'$ ) is strictly smaller than the norm of  $f$  as an element of  $N$ .*

*Proof.* The condition  $J_f = 0$  means that the subspaces  $M$  and  $fA = \{fa : a \in A\}$  form a direct sum (note that it need not be a topological direct sum) equal to  $M_f^0$ . Let  $c = \langle f, f \rangle' \in A$ , and, for  $m + fa, m' + fa' \in M_f^0$ , set

$$\langle m + fa, m' + fa' \rangle_+ = \langle m + fa, m' + fa' \rangle' + a^*ca'.$$

Let us check linearity with respect to the first argument:

$$\begin{aligned} \langle m_1 + m_2 + f(a_1 + a_2), m' + fa' \rangle_+ &= \langle m_1 + m_2 + f(a_1 + a_2), m' + fa' \rangle' + (a_1 + a_2)ca' \\ &= \langle m_1 + fa_1, m' + fa' \rangle' + \langle m_2 + fa_2, m' + fa' \rangle' + (a_1 + a_2)ca' \\ &= \langle m_1 + fa_1, m' + fa' \rangle_+ + \langle m_2 + fa_2, m' + fa' \rangle_+. \end{aligned}$$

Other properties of an inner product obviously hold, making thus  $M_f^0$  a pre-Hilbert  $C^*$ -module with respect to  $\langle \cdot, \cdot \rangle_+$ .

Let us show that  $M_f^0$  is complete with respect to the norm  $\|\cdot\|_+$  determined by the inner product  $\langle \cdot, \cdot \rangle_+$  (it may be not complete with respect to the norm on  $M'$ ).

Suppose that  $\{m_k + fa_k\}_{k \in \mathbb{N}}$  is a Cauchy sequence with respect to  $\|\cdot\|_+$ , where  $m_k \in M$ ,  $a_k \in A$ ,  $k \in \mathbb{N}$ . Note that  $\|fa\|_+ \leq \|m + fa\|_+$  for any  $m \in M$ ,  $a \in A$ , therefore,  $\{fa_k\}_{k \in \mathbb{N}}$  is a Cauchy sequence as well. Then  $\{m_k\}_{k \in \mathbb{N}}$  is Cauchy too.

As  $\langle f, f \rangle' \geq 1$ , we have

$$a^*a \leq a^*\langle f, f \rangle'a = \langle fa, fa \rangle'$$

for any  $a \in A$ , hence

$$\|a_k - a_n\|^2 \leq \langle fa_k - fa_n, fa_k - fa_n \rangle',$$

so  $\{ak\}_{k \in \mathbb{N}}$  is a Cauchy sequence too. As both  $A$  and  $M$  are complete, the limit of the sequence  $\{m_k + fa_k\}_{k \in \mathbb{N}}$  is of the form  $m + fa$  for some  $m \in M$  and  $a \in A$ , thus  $M_f^0$  is complete.

Note that

$$\langle m, m' + fa \rangle_+ = \langle m, m' + fa \rangle' = \langle m, m' \rangle + f(m)a, \quad m, m' \in M, a \in A,$$

hence  $\langle \cdot, \cdot \rangle_+$  is an extension of the inner product  $\langle \cdot, \cdot \rangle$  on  $M$  to  $N$ . As  $M$  is thick in  $M'$ , it is thick in  $N$  as well. Indeed, if  $\langle m, m' + fa \rangle_+ = 0$  for any  $m \in M$  then  $\langle m, m' + fa \rangle' = 0$ , hence  $m' + fa \in M'$  is orthogonal to the whole  $M$ , hence  $m' + fa = 0$ .

Finally,

$$\|f\|' = (\langle f, f \rangle')^{1/2} = \|c\|^{1/2},$$

while

$$\|f\|_+ = (\langle f, f \rangle_+)^{1/2} = (\langle f, f \rangle' + c)^{1/2} = \sqrt{2}\|c\|^{1/2}.$$

$\square$

**Remark 8.** Considering  $\widetilde{M} = A \oplus M$  instead of  $M$ , and  $\widetilde{f} = (\widehat{1}_A, f) \in \widetilde{M}'$  instead of  $f \in M'$ , we get  $\langle \widetilde{f}, \widetilde{f} \rangle' \geq 1$ , and  $J_{\widetilde{f}} = J_f$ , so the condition  $\langle f, f \rangle' \geq 1$  is not restrictive.

#### 4. POSITIVE RESULTS

For a Hilbert  $C^*$ -module  $N$  we write  $\widehat{n}$  for the functional  $x \mapsto \langle n, x \rangle$ .

**Theorem 9.** Let  $M \subset N$  be Hilbert  $C^*$ -modules over a commutative  $W^*$ -algebra  $A = C(X)$  such that  $M$  is countably generated and  $M^\perp = 0$ . Then  $\|n\| = \|\widehat{n}|_M\|$  for any  $n \in N$ , i.e. the map  $n \mapsto \widehat{n}|_M, N \rightarrow M'$ , is an isometry.

*Proof.* If  $M$  is countably generated then it can be considered as a direct summand in the standard Hilbert  $C^*$ -module  $l_2(A)$ , i.e.  $l_2(A) = M \oplus K$  for some Hilbert  $C^*$ -module  $K$ . The functional  $\widehat{n}|_M, n \in N$ , can be similarly considered as a functional on  $l_2(A)$  (defined by zero on  $K$ ). If  $\|n\| \neq \|\widehat{n}|_M\|$  for some  $n \in N$  then the two norms differ for  $(n, 0) \in N \oplus K$ , so the proof reduces to the case when  $M = l_2(A)$ .

Let  $f \in M'$ , and let  $J_f = \{a \in A : fa \in M\}$  be an ideal in  $A$ . We claim that if  $M = l_2(A)$  then  $J_f$  is essential for any  $f \in M'$ , i.e.  $aJ_f = 0, a \in A$ , implies that  $a = 0$ . Let  $f = (f_n)_{n \in \mathbb{N}}, f_n \in C(X)$ . The condition  $f \in M'$  means that  $\sum_{n=1}^{\infty} |f_n|^2$  is bounded. Set  $g_n = \sum_{k=1}^n |f_k|^2$ . As  $A$  is a  $W^*$ -algebra, the least upper bound  $\bar{g}$  of the monotone sequence  $(g_n)_{n \in \mathbb{N}}$  exists and coincides with the pointwise limit  $\check{g} = \lim_{n \rightarrow \infty} g_n$  outside a meager subset  $Y_f$  of  $X$ . We claim that  $J_f$  consists of all functions  $a$  vanishing on  $Y_f$ . Recall that  $fa \in M$  iff the sequence  $\{f_n a\}_{n \in \mathbb{N}}$  is norm convergent.

Suppose that  $a \in A, a|_{Y_f} = 0$ . Given  $\varepsilon > 0$ , set  $U = \{x \in X : |a(x)| < \frac{\varepsilon}{\|\bar{g}\|}\}$ . Clearly,  $U \subset X$  is open, and  $Y_f \subset U$ . Then  $|g_n(x)a(x) - \bar{g}(x)a(x)| \leq \varepsilon$  for any  $x \in U$  and for any  $n \in \mathbb{N}$ . On the compact set  $X \setminus U$ , the sequence  $\{g_n a\}_{n \in \mathbb{N}}$  converges pointwise to the continuous function  $\bar{g}a$ , hence the convergence is uniform — both on  $U$  and on  $X \setminus U$ . Thus,  $a \in J_f$ .

Now, let  $a \in J_f$ . Suppose that there exists  $x_0 \in Y_f$  such that  $a(x_0) \neq 0$ . The sequence  $\{g_n a\}_{n \in \mathbb{N}}$  is uniformly convergent on  $X$ , hence  $\check{g}a$  is continuous and coincides with  $\bar{g}a$ , i.e.  $\bar{g}(x)a(x) = \check{g}(x)a(x)$  for any  $x \in X$ . But  $\bar{g}(x_0) \neq \check{g}(x_0)$ . This contradiction shows that  $a|_{Y_f} = 0$ .

Let us show that the ideal  $J_f$  is essential. Let  $aJ_f = 0$  for some  $a \in C(X)$ . Let  $V = \{x \in X : a(x) \neq 0\}$ . Then  $V$  is an open subset of  $X$ . As  $ab = 0$  for any  $b \in J_f$ , we should have  $b(x) = 0$  for any  $x \in V$ . Recall that if  $C(X)$  is a  $W^*$ -algebra then  $X$  is a hyperstonean space. By Corollary following Proposition 5 of [1], in hyperstonean spaces, any meager set is nowhere dense, i.e. the interior of its closure is empty. Recall that functions in  $J_f$  equal zero on  $Y_f$ , hence, on its closure  $\overline{Y}_f$ . The condition  $aJ_f = 0$  means that for any  $b \in J_f$  one has  $b|_V = 0$ . We claim that this implies  $V \subset \overline{Y}_f$ . Indeed, assume the contrary: let  $x_0 \in V \setminus \overline{Y}_f$  satisfy the condition: any continuous function that vanishes on  $\overline{Y}_f$  vanishes at  $x_0$ . As  $X$  is compact and Hausdorff, it is normal, hence there exists a continuous function that vanishes on  $\overline{Y}_f$  and equals 1 at  $x_0$ . This contradiction proves  $V \subset \overline{Y}_f$ . But  $Y_f$  is nowhere dense, hence the open set  $V$  must be empty. Hence  $a = 0$ . □

Let  $J$  be of  $c_0\text{-}\sum_i \oplus \mathbb{K}(H_i)$ -type, i.e. it has a faithful  $*$ -representation as a  $C^*$ -algebra of compact operators on some Hilbert space, and let  $A \supset J$  be a  $C^*$ -algebra such that  $J$  is an essential ideal in  $A$ . As examples, we may consider  $A = \mathbb{B}(H), J = \mathbb{K}(H)$  and  $A = l_\infty, J = c_0$ .

**Theorem 10.** *Let  $M \subset N$  be Hilbert  $C^*$ -modules over  $A$  such that  $M^\perp = 0$ . Suppose that  $M$  is a Hilbert  $C^*$ -module with a Hilbert dual. If  $A$  is a  $C^*$ -algebra containing an essential ideal  $J$  of  $c_0\text{-}\sum_i \oplus \mathbb{K}(H_i)$ -type then  $\|n\| = \|\widehat{n}|_M\|$  for any  $n \in N$ , i.e. the map  $n \mapsto \widehat{n}|_M$ ,  $N \rightarrow M'$ , is an isometry.*

*Proof.* Denote by  $MJ \subset M$  the norm closure of the linear span of  $\{mj : m \in M, j \in J\}$ . Then  $MJ$  is a Hilbert  $C^*$ -module over  $J$ . Clearly,  $MJ \subset NJ$ . It was shown in [5] that any submodule over  $J$  is orthogonally complemented.

We claim that  $MJ = NJ$ . Indeed, if this is not true then the orthogonal complement for  $MJ$  in  $NJ$  is not zero. Let  $x \in NJ$  satisfy  $x \perp MJ$ . Then  $\langle mj, x \rangle = 0$  for any  $m \in M$  and any  $j \in J$ . As  $J$  is essential, we can conclude that  $\langle m, x \rangle = 0$  for any  $m \in M$ . As  $M^\perp = 0$  in  $N$ , we conclude that  $x = 0$ . It follows that  $nj \in MJ$  for any  $n \in N$  and any  $j \in J$ .

Similarly, consider the inclusion  $M \subset M'$ . Here we have  $M^\perp = 0$  as well. Passing to  $MJ \subset M'J$ , we can conclude that  $fj \in M$  for any  $f \in M'$ . In particular,  $\widehat{n}|_M \cdot j \in M$ .

By assumption,  $M'$  is a Hilbert  $C^*$ -module with the inner product  $\langle \cdot, \cdot \rangle_{M'}$ . By Theorem 6,  $\langle \widehat{n}|_M, \widehat{n}|_M \rangle_{M'} = \langle n, n \rangle_N$  for any  $n \in N$ . □

## 5. NEGATIVE RESULTS

Here we show that the norm of extensions of functionals from thick submodules may be not unique even for commutative monotone complete  $C^*$ -algebras. Take  $X = [0, 1]$ , and consider the  $C^*$ -algebra  $Bor(X)$  of all bounded Borel functions with the sup-norm. Consider the set  $J$  of all functions  $a \in Bor(X)$  such that the set  $\{x \in X : a(x) \neq 0\}$  is meager. The set  $J$  is an ideal in  $Bor(X)$ , so let  $A = B(X) = Bor(X)/J$  be the quotient  $C^*$ -algebra. We denote the equivalence class of  $a$  by  $[a] \in A$ . The  $C^*$ -algebra  $B(X)$  was showed to be monotone complete in [1], while  $Bor(X)$  is only monotone  $\sigma$ -complete [9].

**Lemma 11.** *There exists  $f \in l_2(A)'$  with  $\langle f, f \rangle' \geq 1$  such that  $fa \in l_2(A)$  for  $a \in A$  implies that  $a = 0$ .*

*Proof.* We use the idea from [3] to construct  $f = ([f_1], [f_2], \dots) \in l_2(A)'$  in such a way that the least upper bound for the partial sums of  $\sum_{k=1}^\infty |f_k|^2$  would differ from their pointwise limit on the set of rationals in  $(0, 1)$ . Here  $f_k \in Bor(X)$ ,  $k \in \mathbb{N}$ .

Let  $(r_m)_{m \in \mathbb{N}}$  be the sequence of all rational numbers in  $(0, 1)$  enumerated by natural numbers. For each  $r_m$ , take a strictly increasing sequence  $\alpha_m^k \in (0, 1)$  such that  $\lim_{k \rightarrow \infty} \alpha_m^k = r_m$ , and let  $h_m^k$  be the characteristic function of the interval  $[\alpha_m^k, \alpha_m^{k+1})$ . Fix a bijection

$$\varphi : \mathbb{N} \rightarrow \mathbb{N}^2, \quad \varphi(n) = (m(n), k(n)),$$

and set  $f_n = \frac{1}{2^{m(n)}} h_{m(n)}^{k(n)}$ . Then the partial sums  $\sum_{n=1}^N |f_n|^2$  (and hence  $\sum_{n=1}^N \|[f_n]\|^2$ ) are uniformly bounded, hence  $f = ([f_n])_{n \in \mathbb{N}} \in l_2(A)'$ . Note that we could take continuous functions instead of  $h_n^k$  to get a required  $f$ . To fit the condition  $\langle f, f \rangle' \geq 1$  we may replace the constructed  $f = ([f_1], [f_2], \dots)$  by  $(1_A, [f_1], [f_2], \dots)$ . For shortness' sake set  $g_m = \sum_{k=1}^m |f_k|^2 \in Bor(X)$ .

The series  $\sum_{k=1}^n \|[f_k]\|^2$  is not norm convergent in  $B(X)$  (i.e.  $f \notin l_2(A)$ ). Indeed, note first that  $\|\chi\|_{Bor(X)} = \|\chi\|_{B(X)} = 1$  for a characteristic function  $\chi$  of any open subset of  $X$ . The norm in the quotient algebra is given by

$$\|\chi\|_{B(X)} = \inf_{\psi \in J} \|\chi + \psi\|_{Bor(X)} = 1$$

as  $\psi$  vanishes outside of a meager set. Take any  $N \in \mathbb{N}$ . There exists  $n_0 \in \mathbb{N}$  such that  $m(N + n_0) = 1$ . Then, for any  $M > N + n_0$ , we have  $g_M - g_N \geq \frac{1}{2}h_1^{k(N+n_0)}$ , hence

$$\|[g_M] - [g_N]\| \geq \frac{1}{2}\|[h_1^{k(N+n_0)}]\| = \frac{1}{2}.$$

Moreover, this series is not norm convergent on any closed interval  $[c, d] = V \subset X$ . Let  $\check{q} : \text{Bor}(X) \rightarrow \text{Bor}(V)$  denote the restriction map. It induces the map of the quotients  $q : B(X) \rightarrow B(V)$ . We claim that the series  $\sum_{k=1}^{\infty} q(\|f_k\|)^2$  is not norm convergent. Indeed, take  $m_0$  such that  $r_{m_0} \in V$ , then we can repeat the previous argument. For any  $N \in \mathbb{N}$  we can find  $n_0 \in \mathbb{N}$  such that  $m(N + n_0) = m_0$ . Then, for any  $M > N + n_0$ , we have  $g_M - g_N \geq \frac{1}{2m_0}h_{m_0}^{k(N+n_0)}$ , hence

$$\|[g_M] - [g_N]\| \geq \frac{1}{2m_0}\|[h_{m_0}^{k(N+n_0)}]\| = \frac{1}{2m_0}.$$

Let  $a \in B(X)$  such that  $a \neq 0$  and  $fa \in l_2(A)$ . Set  $b = aa^*$ , then  $b \neq 0$ ,  $b \geq 0$  and  $fb \in l_2(A)$ , so we may replace  $a$  by  $b$ . If we show that  $b = 0$  then  $a = 0$  as well.

Recall that every equivalence class in  $B(X)$  has a lower semicontinuous representative [1], so there exists a lower semicontinuous  $\beta \in \text{Bor}(X)$  such that  $[\beta] = b$ . Let

$$f(t) = \begin{cases} t & \text{if } t \geq 0; \\ 0 & \text{if } t < 0. \end{cases}$$

Then  $[f \circ \beta] = f([\beta]) = f(b) = b$ . As  $f$  is non-decreasing, it is easy to see that  $\alpha = f \circ \beta \in \text{Bor}(X)$  is also lower semicontinuous. We also have  $\alpha(x) \geq 0$  for any  $x \in X$ . As  $b \neq 0$ , there exists  $\varepsilon > 0$  and a non-empty open set  $U \subset X$  such that  $\alpha(x) > \varepsilon$  for any  $x \in U$ . Let  $V \subset U$  be a non-empty closed subset. If the sequence  $\{[g_n]b\}_{n \in \mathbb{N}}$  is norm convergent in  $B(X)$  (i.e. if  $fb \in l_2(A)$ ) then the sequence  $\{q([g_n])\}_{n \in \mathbb{N}}$  is norm convergent in  $B(V)$  too — a contradiction. □

**Corollary 12.** *There exists a monotone complete commutative  $C^*$ -algebra  $A$ , a Hilbert  $C^*$ -module  $N$  over  $A$ , a thick submodule  $M \subset N$ , and  $n \in N$  such that  $\|n\|_N > \|\widehat{n}|_M\|_{M'}$ .*

*Proof.* Let  $A$  be as above,  $M = l_2(A)$ . Take  $f \in l_2(A)'$  as in Lemma 11, i.e. such that  $J_f = 0$ . Then apply Theorem 7. □

There is an interesting consequence of this result. We show that there exist functionals in  $N'$  that equal zero on  $M$ .

Let  $M \subset N$ , and suppose that both  $M$  and  $N$  are Hilbert  $C^*$ -modules with a Hilbert dual. Denote the inclusion  $M \rightarrow N$  by  $\alpha$ , and define the map  $P : N' \rightarrow M'$  by  $P(g)(m) = g(\alpha(m))$ ,  $g \in N'$ ,  $m \in M$ . As the dual modules are Hilbert  $C^*$ -modules, this can be written as

$$(1) \quad \langle \widehat{m}, P(g) \rangle_{M'} = \langle \widehat{\alpha(m)}, g \rangle_{N'}.$$

As the dual modules are Hilbert  $C^*$ -modules, they are self-dual, i.e. equal to their second duals. Therefore, all bounded operators are adjointable. Let  $I = P^* : M' \rightarrow N'$ . Then  $\langle f, P(g) \rangle_{M'} = \langle I(f), g \rangle_{N'}$ ,  $f \in M'$ . Taking  $f = \widehat{m}$ ,  $m \in M$ , we get

$$(2) \quad \langle \widehat{m}, P(g) \rangle_{M'} = \langle I(\widehat{m}), g \rangle_{N'}.$$

Comparing (1) and (2), we see that  $I(\widehat{m}) = \widehat{\alpha(m)}$  for any  $m \in M$ .

**Theorem 13.** *Let  $M \subset N$  be a thick submodule, let both  $M$  and  $N$  are Hilbert  $C^*$ -modules with a Hilbert dual. Then the map  $I : M' \rightarrow N'$  is an isometric inclusion. If there exists  $n \in N$  such that  $\|n\|_N > \|\widehat{n}|_M\|_{M'}$  then  $N' = I(M') \oplus K$  for some non-zero  $K$ .*

*Proof.* Let us calculate the composition  $PI : M' \rightarrow M'$ . For  $m, m' \in M$ , we have

$$\begin{aligned} \langle PI(\widehat{m}), \widehat{m}' \rangle_{M'} &= \langle I(\widehat{m}), I(\widehat{m}') \rangle_{N'} \\ &= \langle \widehat{\alpha(m)}, \widehat{\alpha(m')} \rangle_{N'} \\ &= \langle \alpha(m), \alpha(m') \rangle_N \\ &= \langle m, m' \rangle_M \\ &= \langle \widehat{m}, \widehat{m}' \rangle_{M'}, \end{aligned}$$

hence,  $\langle PI(\widehat{m}) - \widehat{m}, \widehat{m}' \rangle_{M'} = 0$  for any  $m' \in M$ , thus, as  $M \subset M'$  is thick, we conclude that  $PI(\widehat{m}) = \widehat{m}$  for any  $m \in M$ .

Note that  $PI$  is selfadjoint, and  $(PI)|_M = \text{id}_M$ . This suffices to show that  $PI = \text{id}_{M'}$ :

$$\langle PI(f), \widehat{m} \rangle_{M'} = \langle f, PI(\widehat{m}) \rangle_{M'} = \langle f, \widehat{m} \rangle_{M'}, \quad f \in M',$$

hence, by thickness of  $M$  in  $M'$ , we conclude that  $PI(f) = f$  for any  $f \in M'$ .

Then  $IP : N' \rightarrow N'$  is a projection with range  $M'$ , and both  $P$  and  $I$  are contractions. It follows from (1) that

$$\langle \widehat{m}, P(\widehat{n}) \rangle_{M'} = \langle \widehat{\alpha(m)}, \widehat{n} \rangle_{N'} = \langle \alpha(m), n \rangle_N = \widehat{n}|_M(m)$$

for any  $m \in M$ ,  $n \in N$ , hence  $P(\widehat{n}) = \widehat{n}|_M$  for any  $n \in N$ .

Let  $n \in N$  satisfy  $\|n\|_N > \|\widehat{n}|_M\|_{M'}$ . Then  $\|P(\widehat{n})\|_{M'} < \|n\|_N$ , hence  $\|IP(\widehat{n})\| < \|n\|_N$ . If  $IP = \text{id}_{N'}$  then this cannot be true, hence the projection  $IP$  is not the identity map. Set  $K = (\text{id}_{N'} - IP)(N')$ . □

**Corollary 14.** *Let  $M \subset N$  be a thick submodule, and let both  $M$  and  $N$  be Hilbert  $C^*$ -modules with a Hilbert dual. If there exists  $n \in N$  such that  $\|n\|_N > \|\widehat{n}|_M\|_{M'}$  then there exists  $g \in N'$  such that  $g|_M = 0$ .*

*Proof.* Let  $K$  be as in Theorem 13, and let  $g \in K$ ,  $g \neq 0$ . Then  $\langle g, f' \rangle = 0$  for any  $f \in M'$ , hence  $g|_M = 0$ . □
