ON THE NON-TRIVIALITY OF RANKIN–SELBERG L -VALUES IN HIDA FAMILIES

CHAN-HO KIM AND MATTEO LONGO

ABSTRACT. The aim of this paper is to prove the two-variable anticyclotomic Iwasawa main conjecture for Hida families and a definite version of the horizontal non-vanishing conjecture, which are formulated in [LV11]. Our approach is based on the two-variable anticyclotomic control theorem for Selmer groups for Hida families and the relation between the two-variable anticyclotomic L -function for Hida families built out of p -adic families of Gross points on definite Shimura curves studied in [CL16] and [CKL17] and the self-dual twist of the specialisation to the anticyclotomic line of the three-variable p -adic L -function of Skinner–Urban [SU14].

1. INTRODUCTION

To state our main results, fix a prime $p \geq 5$ and an integer N with $p \nmid N$, and let \mathcal{R} be a primitive branch of a Hida family of p -adic modular forms of tame conductor N ; more precisely, \mathcal{R} is a noetherian domain, finite and flat over the Iwasawa algebra $\Lambda = \mathcal{O}[[1 + p\mathbb{Z}_p]]$, where \mathcal{O} is the valuation ring of a fixed finite extension of \mathbb{Q}_p . Let $\mathbf{f} = \sum_{n \geq 1} \mathbf{a}_n q^n \in \mathcal{R}[[q]]$ denote the Hida family of p -adic modular forms associated with \mathcal{R} . For each arithmetic prime $\kappa : \mathcal{R} \rightarrow F_\kappa \subseteq \overline{\mathbb{Q}_p}$, where F_κ is a finite extension of \mathbb{Q}_p , the specialisation $f_\kappa = \sum_{n \geq 1} \kappa(\mathbf{a}_n) q^n \in F_\kappa[[q]]$ of \mathbf{f} at κ is a p -ordinary cuspform of level $\Gamma_1(Np^{s_\kappa})$, weight k_κ and character ψ_κ , for an integer $s_\kappa \geq 1$ and an integer $k_\kappa \geq 2$; see §3.1 for a more accurate exposition.

Let \mathbf{T}^\dagger denote the self-dual twist of Hida’s big Galois representation attached to \mathcal{R} ; therefore, \mathbf{T}^\dagger is a free \mathcal{R} -module of rank 2, and for each arithmetic prime $\kappa : \mathcal{R} \rightarrow F_\kappa$, the specialisation $V_\kappa^\dagger = \mathbf{T}^\dagger \otimes_{\mathcal{R}, \kappa} F_\kappa$ at κ is isomorphic to the base change to F_κ of the self-dual twist of Deligne’s Galois representation attached to the modular form f_κ . Let $\mathbf{A}^\dagger = \mathbf{T}^\dagger \otimes_{\mathcal{R}} \mathcal{R}^\vee$. Here, $(-)^{\vee}$ means the Pontryagin dual.

Let K be a quadratic imaginary field of discriminant prime to Np , and write the factorisation $N = N^+ N^-$ where a prime divisor ℓ of N divides N^+ if and only if it is split in K . Throughout the paper, we place ourselves in the *definite setting*; more precisely, we assume that

- N^- is a square-free product of an odd number of distinct primes; we also assume that p is split in K .

If f_κ has trivial character, the order of vanishing at $s = k/2$ of the L -series $L(f_\kappa/K, s)$ of f_κ over K is even by the assumption above on N^- , and therefore, in light of an analogue in this setting of Greenberg’s conjecture, one expects that these L -values do not generically vanish when the order of vanishing of the L -series $L(f_\kappa, s)$ of f_κ over \mathbb{Q} is also even. As a consequence

of the Tamagawa number conjecture of Bloch–Kato, one expects that the Bloch–Kato Selmer groups of V_κ^\dagger over K is generically trivial in the same setting, so one expects that Nekovář extended Selmer group of \mathbf{A}^\dagger over K is a cotorsion \mathcal{R} -module. when the order of vanishing of the L -series $L(f_\kappa, s)$ of f_κ over \mathbb{Q} is even. See [LV11, Conjecture 9.5] for a more detailed discussion of this heuristic.

Denote by K_∞ the anticyclotomic \mathbb{Z}_p -extension of K , and denote $\Gamma_\infty = \text{Gal}(K_\infty/K) \simeq \mathbb{Z}_p$. In [LV11] a big theta element $\Theta_\infty(\mathbf{f})$ in $\mathcal{R}[[\Gamma_\infty]]$ is constructed by means of compatible families of Gross points on towers of Shimura curves associated with the definite quaternion algebra B ramified at all primes dividing N^- and Eichler orders of increasing p -power level; we also define the two-variable anticyclotomic p -adic L -function

$$L_p(\mathbf{f}/K) = \Theta_\infty(\mathbf{f}) \cdot \Theta_\infty(\mathbf{f})^*,$$

where $x \mapsto x^*$ is the involution of $\mathcal{R}[[\Gamma_\infty]]$ defined by $\gamma \mapsto \gamma^{-1}$ on group-like elements. The construction $\Theta_\infty(\mathbf{f})$, $L_p(\mathbf{f}/K)$, and the notion of compatibility of Gross points on towers of Shimura curves, is reviewed in §3.3.

The element $L_p(\mathbf{f}/K)$ is the analogue of the p -adic L -function $L_p(E/K)$ introduced by Bertolini–Darmon [BD96a], [BD96b] and [BD05] using Gross points on definite Shimura curves to study the arithmetic of elliptic curves over K in a similar definite setting. In particular, if the conductor N of E admits the same factorisation $N = N^+N^-$ as above and p is a prime of good ordinary reduction for E which splits in K , then, under mild technical hypothesis, it is known that the p -adic L -function $L_p(E/K)$ is a non-trivial element of $\mathbb{Z}_p[[\Gamma_\infty]]$, the Pontryagin dual of the Selmer group of the p -power torsions of E over K_∞ is a torsion $\mathbb{Z}_p[[\Gamma_\infty]]$ -module and its characteristic ideal is equal to the ideal generated by the p -adic L -function (see [BD05, Theorem 1] and [SU14, Theorem 3.37]). Therefore, it is natural to expect a similar main conjecture holds for families. In other words, if $\mathcal{R}[[\Gamma_\infty]]$ is the Iwasawa algebra of Γ_∞ with coefficients in \mathcal{R} , then one expects that the two-variable p -adic L -function $L_p(\mathbf{f}/K)$ is a non-zero element of $\mathcal{R}[[\Gamma_\infty]]$, the Selmer group of \mathbf{A}^\dagger over K_∞ is a cotorsion $\mathcal{R}[[\Gamma_\infty]]$ -module, and its characteristic ideal is equal to the ideal generated by the p -adic L -function. See [LV11, §9.3] for a more detailed discussion of this topic. The proof of these assertions is one of the main result of this paper, from which we also deduce some results on the Selmer group of \mathbf{T}^\dagger over K .

Let $\tilde{H}_f^1(K_\infty, \mathbf{A}^\dagger)$ be Nekovář extended Selmer group of \mathbf{A}^\dagger over K_∞ and $\tilde{H}_f^1(K_\infty, \mathbf{A}^\dagger)^\vee$ its Pontryagin dual, which are discrete and compact $\mathcal{R}[[\Gamma_\infty]]$ -modules, respectively. Before stating our main results, we fix our assumptions. We suppose that there exists an arithmetic prime κ_0 such that $f_0 = f_{\kappa_0} = \sum_{n \geq 1} a_n q^n \in S_{\kappa_0}(\Gamma_0(Np))$ is an ordinary p -stabilised newform of weight $k_0 \geq 2$ with $k_0 \equiv 2 \pmod{p-1}$ and trivial nebentypus character. We denote $\bar{\rho}_{f_0}$ the residual representation attached to f_0 .

Our first main result is the two-variable anticyclotomic Iwasawa main conjecture for Hida families, which proves [LV11, Conjecture 9.12].

Theorem 1.1. *We assume the following statements.*

- N^- is a square-free product of an odd number of distinct primes.
- The residual representation $\bar{\rho}_{f_0}$ is absolutely irreducible, p -distinguished, and ramified at all primes $\ell \mid N^-$.
- p is a non-anomalous prime for $\bar{\rho}_{f_0}$ when $k = 2$, i.e. $a_p(f_0) \not\equiv \pm 1$ modulo the maximal ideal of \mathcal{O} .
- p is split in K .

Then $\tilde{H}_f^1(K_\infty, \mathbf{A}^\dagger)^\vee$ is a cotorsion $\mathcal{R}[[\Gamma_\infty]]$ -module, and its characteristic ideal is equal to the ideal generated by the two-variable p -adic L -function $L_p(\mathbf{f}/K)$.

We also deduce a result on the arithmetic of \mathbf{f} over K , which is an definite analogue of the horizontal non-vanishing conjecture [LV11, Conjecture 9.5]. Define $\mathcal{J}_0 = \chi_{\text{triv}}(\Theta_\infty(\mathbf{f}))$, where χ_{triv} is the trivial character of Γ_∞ and let $\tilde{H}_f^1(K, \mathbf{T}^\dagger)$ denote Nekovář extended Selmer group of \mathbf{T}^\dagger over K_∞ .

Theorem 1.2. *Under the same assumptions in Theorem 1.1, if $\tilde{H}_f^1(K, \mathbf{T}^\dagger)$ is a torsion \mathcal{R} -module, then $\mathcal{J}_0 \neq 0$.*

The proofs of these results are the combination of the following ingredients.

- A control theorem for Selmer groups of Hida’s big Galois representations over the anti-cyclotomic \mathbb{Z}_p -extension, similar to analogous results for the cyclotomic \mathbb{Z}_p -extension by Ochiai [Och06], which we prove in §2.6 of this paper;
- The results from [CL16], [CKL17] and [KL22] proving a close relation between $L_p(\mathbf{f}/K)$ and the self-dual twist of the specialisation to the anticyclotomic line of the three-variable p -adic L -functions of Skinner–Urban [SU14];
- The three-variable Iwasawa main conjecture proved by Skinner–Urban [SU14].

As hinted from the lines above, the proof of the three-variable main conjecture in [SU14] has a prominent role in our argument; however, the careful comparison of the two setting is required, for which we use the results from [CL16], [CKL17] and [KL22].

2. SELMER GROUPS OVER ORDINARY DEFORMATION RINGS AND THEIR CONTROL THEOREM

In this section, we first review Iwasawa algebras over complete noetherian regular local rings of Krull dimension ≥ 1 and Selmer groups of ordinary Galois representations over such rings. Then we prove a general control theorem for these Selmer groups and relate them with classical Selmer groups via Shapiro’s lemma. This generality certainly includes the case of Hida deformations. The notation of this section is independent of the notation of the other sections of the paper. Some of the arguments are similar to those in [Och00], [Och01], and [Och06].

We first set some general convention. Let R be a complete noetherian regular local ring with maximal ideal \mathfrak{m}_R , of Krull dimension $d \geq 1$, with finite residue field $k = R/\mathfrak{m}_R R$ of characteristic p , a prime number. For any ideal $I \subseteq R$, and any R -module M , denote $M[I]$ the I -torsion R -submodule of M and M_I the localization of M at I . Denote

$$M^* = \text{Hom}_R(M, R)$$

the R -linear dual of M (where Hom_R denotes R -linear homomorphisms) and

$$M^\vee = \text{Hom}_{\text{cont}}(M, \mathbb{Q}_p/\mathbb{Z}_p)$$

the Pontryagin dual of M (where Hom_{cont} denotes continuous group homomorphisms). By [Nek06, §2.9.1, §2.9.2],

$$M^\vee = D(M) = \text{Hom}_R(M, R^\vee)$$

under our assumptions for any R -module M of finite type, hence compact, or any R -module M of cofinite type equipped with the discrete topology. Following [Nek06, §0.4], define

$$\Phi(M) = M \otimes_R R^\vee.$$

In particular, $(M^*)^\vee \simeq \Phi(M)$ and $(\Phi(M))^\vee \simeq M^*$ for any R -module M of finite type ([Nek06, (0.4.4)]). Further, by basic properties of Pontryagin duality, $(M[\mathfrak{p}])^\vee \simeq M^\vee/\mathfrak{p}M^\vee$ and, if M is a G -module for some profinite group G , we have $(M^G)^\vee \simeq (M^\vee)_G$.

2.1. Iwasawa algebras over regular local rings. Fix a complete noetherian regular local ring R , with maximal ideal \mathfrak{m}_R , of Krull dimension $d \geq 1$, and finite residue field $k = R/\mathfrak{m}_R$ of characteristic p , a prime number. Let F_∞/F be a \mathbb{Z}_p -extension of F , unramified outside p and totally ramified at p , and define $G_\infty = \text{Gal}(F_\infty/F) \simeq \mathbb{Z}_p$. Let F_n be the subfield of F_∞ such that $G_n = \text{Gal}(F_n/F) \simeq \mathbb{Z}/p^n\mathbb{Z}$ and define

$$\Lambda_R = R[[G_\infty]] = \varprojlim_n R[G_n].$$

We recall briefly some properties of Λ_R and finitely generated Λ_R -modules. We begin with the following standard fact.

Lemma 2.1. *The ring Λ_R is isomorphic to the power series ring $R[[X]]$ via the map which sends a topological generator γ of G_∞ to $X - 1$.*

Since R is a complete noetherian regular local ring, thanks to Lemma 2.1 we see that Λ_R is also a complete noetherian regular local ring with maximal ideal $\mathfrak{m}_{\Lambda_R} = (\mathfrak{m}_R, \gamma - 1)$ of Λ_R ([Mat89, Theorem 3.3, Exercise 8.6, Theorem 19.5]). In particular, since R and Λ_R are regular local ring, they are also UFD by Auslander–Buchsbaum Theorem ([Mat89, Theorems 20.3 and 20.8]), and therefore every prime ideal of height 1 of R and Λ_R is principal ([Mat89, Theorem 20.1]), and R and Λ_R are integrally closed ([Mat89, §9, Example 1]).

Recall that a Λ_R -module X is said to be *pseudo-null* if its support $\text{Supp}_{\Lambda_R}(X)$ contains only prime ideals of height at least 2, and that two Λ_R -modules X and Y are said to be *pseudo-isomorphic* if there exists an exact sequence

$$0 \longrightarrow A \longrightarrow X \longrightarrow Y \longrightarrow B \longrightarrow 0$$

where A and B are pseudo-null Λ_R -modules ([Bou98, Chapter VII, §4, no.4, Definitions 2 and 3]). Since Λ_R is noetherian and integrally closed, we see from [Bou98, Chapter VII, §4, no.4, Theorem 4] that every finitely generated Λ_R -module M is pseudo-isomorphic to the Λ_R -module $T \times Q$, where T is the maximal torsion Λ_R -submodule of M and Q is a free Λ_R -module. By [Bou98, Chapter VII, §4, no.4, Theorem 5], we know that T is isomorphic to $\bigoplus_{i=1}^t \Lambda_R/\mathfrak{p}_i^{n_i}$ for suitable height 1 prime ideals \mathfrak{p}_i of Λ_R and integers $n_i \geq 1$; moreover, since every prime ideal of Λ_R is principal, there are prime (hence irreducible) elements $g_i \in \Lambda_R$ such that $T \simeq \bigoplus_{i=1}^s \Lambda_R/g_i^{n_i}$. Define the *characteristic ideal* $\text{Char}_{\Lambda_R}(M)$ of M to be 0 if $Q \neq 0$ and

$$\text{Char}_{\Lambda_R}(M) = \left(\prod_{i=1}^s g_i^{n_i} \right)$$

otherwise.

Lemma 2.2. *Let Q be a finitely generated Λ_R -module and $\mathfrak{p} = (g)$ a principal prime ideal of Λ_R . Assume that $Q/\mathfrak{p}Q$ is pseudo-null. Then the \mathfrak{p} -torsion Λ_R -submodule $Q[\mathfrak{p}]$ of Q is isomorphic to $S[\mathfrak{p}]$, where S is the maximal pseudo-null Λ_R -submodule of Q .*

Proof. The theory of Λ_R -modules recalled above shows the existence of an exact sequence

$$(1) \quad 0 \longrightarrow S \longrightarrow Q \longrightarrow M = U \oplus \left(\bigoplus_{i=1}^s \Lambda_R/g_i^{n_i} \Lambda_R \right) \longrightarrow B \longrightarrow 0$$

where $g_i \in \Lambda_R$ are irreducible elements, $n_i \geq 1$ are integers, U is free over Λ_R , and S and B are pseudo-null. It suffices to show that the multiplication by g map is injective on M .

Since U is torsion-free, the multiplication by g map is injective on U .

We now make the following observation. Suppose that $g_i \mid g$ for some i . Then $\mathfrak{p} = (g) = (g_i)$ since g is irreducible. This, the quotient ring $\Lambda_R/(g, g_i^{n_i})\Lambda_R$ is isomorphic to $\Lambda_R/\mathfrak{p}\Lambda_R$, which is not pseudo-null, and therefore $M/\mathfrak{p}M$ is not pseudo-null. Since subquotients of pseudo-null Λ_R -modules are again pseudo-null, from (1) we have a pseudo-isomorphism between the pseudo-null Λ_R -module $Q/\mathfrak{p}Q$ and the Λ_R -module $M/\mathfrak{p}M$ which is not pseudo-null. Hence, $g_i \nmid g$ for every i under our assumption.

We now study the multiplication by g map on the torsion Λ_R -submodule of M . Suppose that $g \cdot [m] = 0$ for some class $[m] \in \Lambda_R/g_i^{n_i}\Lambda_R$, where $m \in \Lambda_R$. Then $g \cdot m$ belongs to $g_i^{n_i}$. Since $g_i^{n_i} \mid g \cdot m$ and $g_i \nmid g$, we conclude that $g_i^{n_i} \mid m$, so $[m] = 0$. Thus the multiplication by g map is injective on $\Lambda_R/g_i^{n_i}\Lambda_R$. We conclude that the multiplication by g map $M \xrightarrow{\times g} M$ is injective, and therefore the \mathfrak{p} -torsion Λ_R -submodule $Q[\mathfrak{p}]$ of Q is isomorphic to the \mathfrak{p} -torsion Λ_R -submodule of S , as was to be shown. \square

2.2. Selmer groups over Iwasawa algebras. Let F be an algebraic number field. For each place v of F , denote F_v the completion of F at v and \mathcal{O}_{F_v} the valuation ring of F_v . Define $G_F = \text{Gal}(\bar{F}/F)$ and $G_{F_v} = \text{Gal}(\bar{F}_v/F_v)$. Let I_{F_v} the inertia subgroup of G_{F_v} . We will also write $\mathcal{O}_v = \mathcal{O}_{F_v}$, $I_v = I_{F_v}$ and $G_v = G_{F_v}$ when the fields involved are clear from the context. Recall that F_∞/F is a fixed \mathbb{Z}_p -extension of F , unramified outside p and totally ramified at p , $G_\infty = \text{Gal}(F_\infty/F)$ and F_n is the subfield of F_∞ such that $G_n = \text{Gal}(F_n/F) \simeq \mathbb{Z}/p^n\mathbb{Z}$; finally, recall that $\Lambda_R = R[[G_\infty]]$.

Let \mathbf{T} be finite free Λ_R -module equipped with a continuous action of G_F , and fix a prime number p a prime number. Let Σ_p denote the set of places of F dividing p , and let Σ be a finite set of places of F containing Σ_p . We assume that \mathbf{T} is unramified outside Σ . Moreover, for each $v \mid p$ a prime of the ring of integers \mathcal{O} of F , we suppose given a filtration

$$(2) \quad 0 \longrightarrow F_v^+(\mathbf{T}) \longrightarrow \mathbf{T} \longrightarrow F_v^-(\mathbf{T}) \longrightarrow 0$$

of $G_v = \text{Gal}(\bar{F}_v/F_v)$ -modules.

Remark 2.3. For the moment, we do not impose any condition to the filtration (2), but of course the structure of the Selmer group defined below depends on this choice. In the applications, the filtration (2) is made of Λ_R -modules $F_v^+(\mathbf{T})$ and $F_v^-(\mathbf{T})$ which are both free of rank 1, and the Galois action on each of them is characterised by a pair of characters, one unramified and the other factorising through the cyclotomic \mathbb{Z}_p -extension of F . See §2.4 for details.

Taking Φ (*i.e.* tensoring over Λ_R with Λ_R^\vee) we also get a filtration

$$0 \longrightarrow F_v^+(\mathbf{A}) \longrightarrow \mathbf{A} \longrightarrow F_v^-(\mathbf{A}) \longrightarrow 0.$$

Define the *Greenberg Selmer group of \mathbf{A}* (relative to the chosen filtrations (2)) by

$$\text{Sel}(F, \mathbf{A}) = \ker \left(H^1(F, \mathbf{A}) \longrightarrow \prod_{v \notin \Sigma_p} H^1(I_v, \mathbf{A}) \times \prod_{v \in \Sigma_p} H^1(I_v, \mathbf{A}/F_v^+(\mathbf{A})) \right)$$

and the *strict Greenberg Selmer group of \mathbf{A}* (relative to the chosen filtrations (2)) by

$$\text{Sel}_{\text{str}}(F, \mathbf{A}) = \ker \left(H^1(F, \mathbf{A}) \longrightarrow \prod_{v \notin \Sigma_p} H^1(I_v, \mathbf{A}) \times \prod_{v \in \Sigma_p} H^1(F_v, \mathbf{A}/F_v^+(\mathbf{A})) \right)$$

where I_v is the inertia subgroup of G_v .

Let $\mathfrak{q} = (g) \subseteq \Lambda_R$ be a principal ideal and assume that $\Lambda_R/\mathfrak{q}\Lambda_R$ is finite and flat over R . Since $\Lambda_R/\mathfrak{q}\Lambda_R$ is flat over R , tensoring over R with $\Lambda_R/\mathfrak{q}\Lambda_R$ we also have a filtration

$$0 \longrightarrow F_v^+(\mathbf{T}/\mathfrak{q}\mathbf{T}) \longrightarrow \mathbf{T}/\mathfrak{q}\mathbf{T} \longrightarrow F_v^-(\mathbf{T}/\mathfrak{q}\mathbf{T}) \longrightarrow 0$$

where $\mathbf{T}/\mathfrak{q}\mathbf{T} = \mathbf{T} \otimes_{\Lambda_R} \Lambda_R/\mathfrak{q}\Lambda_R = T \otimes_R \Lambda_R/\mathfrak{q}\Lambda_R$. We also have a filtration

$$0 \longrightarrow F_v^+(\mathbf{A}[\mathfrak{q}]) \longrightarrow \mathbf{A}[\mathfrak{q}] \longrightarrow F_v^-(\mathbf{A}[\mathfrak{q}]) \longrightarrow 0$$

where $F_v^+(\mathbf{A}[\mathfrak{q}]) = A[\mathfrak{q}] \cap F_v^+(\mathbf{A})$. Define the *Greenberg Selmer group of $\mathbf{A}[\mathfrak{q}]$* (relative to the chosen filtrations (2)) by

$$\mathrm{Sel}(F, \mathbf{A}[\mathfrak{q}]) = \ker \left(H^1(F, \mathbf{A}[\mathfrak{q}]) \longrightarrow \prod_{v \notin \Sigma_p} H^1(I_v, \mathbf{A}[\mathfrak{q}]) \times \prod_{v \in \Sigma_p} H^1(I_v, \mathbf{A}[\mathfrak{q}]/F_v^+(\mathbf{A}[\mathfrak{q}])) \right)$$

and the *strict Greenberg Selmer group of \mathbf{A}* (relative to the chosen filtrations (2)) by

$$\mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A}[\mathfrak{q}]) = \ker \left(H^1(F, \mathbf{A}[\mathfrak{q}]) \longrightarrow \prod_{v \notin \Sigma_p} H^1(I_v, \mathbf{A}[\mathfrak{q}]) \times \prod_{v \in \Sigma_p} H^1(F_v, \mathbf{A}/F_v^+(\mathbf{A}[\mathfrak{q}])) \right).$$

2.3. The control theorem. Let the notation be as in §2.2. Let $\mathfrak{q} = (g) \subseteq \Lambda_R$ be a principal ideal and assume that $\Lambda_R/\mathfrak{q}\Lambda_R$ is finite and flat over R . Then we have canonical maps

$$\begin{aligned} r_{\mathfrak{q}} &: \mathrm{Sel}(F, \mathbf{A}[\mathfrak{q}]) \longrightarrow \mathrm{Sel}(F, \mathbf{A})[\mathfrak{q}], \\ r_{\mathfrak{q}}^{\mathrm{str}} &: \mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A}[\mathfrak{q}]) \longrightarrow \mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A})[\mathfrak{q}]. \end{aligned}$$

Proposition 2.4. *Assume that $H^0(F, \mathbf{A}[\mathfrak{q}])^\vee$ is a pseudo-null Λ_R -module. Then $\ker(r_{\mathfrak{q}})^\vee$ and $\ker(r_{\mathfrak{q}}^{\mathrm{str}})^\vee$ are also pseudo-null Λ_R -modules, and are contained in the \mathfrak{q} -torsion subgroup of the maximal pseudo-null Λ_R -submodule of $(\mathbf{T}^*)_{G_F}$.*

Proof. We do the proof only for $r_{\mathfrak{q}}$; the case of $r_{\mathfrak{q}}^{\mathrm{str}}$ is verbatim.

We have the following commutative diagram:

$$\begin{array}{ccccc} & & \mathrm{Sel}(F, \mathbf{A}[\mathfrak{q}]) & \xrightarrow{r_{\mathfrak{q}}} & \mathrm{Sel}(F, \mathbf{A})[\mathfrak{q}] \\ & & \downarrow & & \downarrow \\ H^0(F, \mathbf{A})/\mathfrak{q}H^0(F, \mathbf{A}) & \longrightarrow & H^1(F, \mathbf{A}[\mathfrak{q}]) & \longrightarrow & H^1(F, \mathbf{A})[\mathfrak{q}] \end{array}$$

therefore it is enough to show that $H^0(F, \mathbf{A})/\mathfrak{q}H^0(F, \mathbf{A})$ is a pseudo-null Λ_R -module, and that it is contained in the \mathfrak{q} -torsion subgroup of the maximal pseudo-null Λ_R -submodule of $(\mathbf{T}^*)_{G_F}$.

Note that $H^0(F, \mathbf{A}[\mathfrak{q}]) = H^0(F, \mathbf{A})[\mathfrak{q}]$ is the Pontryagin dual of $(\mathbf{T}^*)_{G_F}/\mathfrak{q}(\mathbf{T}^*)_{G_F}$, and that $H^0(F, \mathbf{A})/\mathfrak{q}H^0(F, \mathbf{A})$ is the Pontryagin dual of $(\mathbf{T}^*)_{G_F}[\mathfrak{q}]$. Since $H^0(F, \mathbf{A}[\mathfrak{q}])^\vee$ is a pseudo-null Λ_R -module by assumption, applying Lemma 2.2 to the Λ_R -module $(\mathbf{T}^*)_{G_F}$ we see that $H^0(F, \mathbf{A})/\mathfrak{q}H^0(F, \mathbf{A})$ has also pseudo-null Pontryagin dual, contained in the \mathfrak{q} -torsion subgroup of the maximal pseudo-null Λ_R -submodule of $(\mathbf{T}^*)_{G_F}$. \square

For $v \in \Sigma$, define

$$C_v = \begin{cases} \Lambda_R\text{-torsion submodule of the module } ((\mathbf{T}/F_v^+(\mathbf{T}))^*)_{I_v} & \text{if } v \in \Sigma_p, \\ \Lambda_R\text{-torsion submodule of the module } (\mathbf{T}^*)_{I_v} & \text{if } v \in \Sigma - \Sigma_p. \end{cases}$$

$$C_v^{\mathrm{str}} = \begin{cases} \Lambda_R\text{-torsion submodule of the module } ((\mathbf{T}/F_v^+(\mathbf{T}))^*)_{G_v} & \text{if } v \in \Sigma_p, \\ \Lambda_R\text{-torsion submodule of the module } (\mathbf{T}^*)_{I_v} & \text{if } v \in \Sigma - \Sigma_p. \end{cases}$$

Denote F_Σ the maximal extension of F which is unramified outside Σ .

Proposition 2.5. *Assume that*

- *The Λ_R -module $C_v/\mathfrak{q}C_v$ ($C_v^{\mathrm{str}}/\mathfrak{q}C_v^{\mathrm{str}}$, respectively) is pseudo-null for each $v \in \Sigma$;*
- *$H^0(F_\Sigma/F, \mathbf{A}[\mathfrak{q}])^\vee$ is pseudo-null.*

Then $\mathrm{coker}(r_{\mathfrak{q}})^\vee$ ($\mathrm{coker}(r_{\mathfrak{q}}^{\mathrm{str}})^\vee$, respectively) is a pseudo-null Λ_R -module.

Proof. We do the proof only for $r_{\mathfrak{q}}$; the case of $r_{\mathfrak{q}}^{\text{str}}$ is verbatim.

Recall that

$$H^1(F_{\Sigma}/F, \mathbf{A}) = \ker \left(H^1(F, \mathbf{A}) \longrightarrow \prod_{v \notin \Sigma} H^1(I_v, \mathbf{A}) \right)$$

as a submodule of $H^1(F, \mathbf{A})$. It follows that there exists a commutative diagram:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \text{Sel}(F, \mathbf{A}[\mathfrak{q}]) & \longrightarrow & H^1(F_{\Sigma}/F, \mathbf{A}[\mathfrak{q}]) & \xrightarrow{\gamma_{\mathfrak{q}}} & \prod_{p \in \Sigma_p} H^1(I_v, (\mathbf{A}/F_v^+(\mathbf{A}))[\mathfrak{q}]) \times \prod_{v \in \Sigma - \Sigma_p} H^1(F_v, \mathbf{A}[\mathfrak{q}]) \\ & & \downarrow r_{\mathfrak{q}} & & \downarrow s_{\mathfrak{q}} & & \downarrow t_{\mathfrak{q}} \\ 0 & \longrightarrow & \text{Sel}(F, \mathbf{A})[\mathfrak{q}] & \longrightarrow & H^1(F_{\Sigma}/F, \mathbf{A})[\mathfrak{q}] & \longrightarrow & \prod_{p \in \Sigma_p} H^1(I_v, (\mathbf{A}/F_v^+(\mathbf{A}))[\mathfrak{q}]) \times \prod_{v \in \Sigma - \Sigma_p} H^1(F_v, \mathbf{A})[\mathfrak{q}] \end{array}$$

where the vertical arrows are restriction maps. The multiplication by g map induces an exact sequence

$$0 \longrightarrow \mathbf{A}[\mathfrak{q}] \longrightarrow \mathbf{A} \xrightarrow{g} \mathfrak{q}\mathbf{A} \longrightarrow 0$$

which shows that map $s_{\mathfrak{q}}$ is surjective. Therefore by the snake lemma the cokernel of $r_{\mathfrak{q}}$ is a subquotient of the kernel of $t_{\mathfrak{q}}$. Therefore, it is enough to show that the Pontryagin dual $\ker(t_{\mathfrak{q}})^{\vee}$ of $\ker(t_{\mathfrak{q}})$ is pseudo-null. The module $\ker(t_{\mathfrak{q}})$ is isomorphic to

$$\begin{aligned} \ker(t_{\mathfrak{a}}) &\simeq \text{coker} \left(\prod_{p \in \Sigma_p} H^0(I_v, \mathbf{A}/F_v^+(\mathbf{A})) \times \prod_{v \in \Sigma - \Sigma_p} H^0(F_v, \mathbf{A}) \xrightarrow{g} \prod_{p \in \Sigma_p} H^0(I_v, \mathbf{A}/F_v^+(\mathbf{A})) \times \prod_{v \in \Sigma - \Sigma_p} H^0(F_v, \mathbf{A}) \right) \\ &\simeq \ker \left(\prod_{v \in \Sigma - \Sigma_p} (\mathbf{T}^*)_{I_v} \times \prod_{v \in \Sigma_p} ((\mathbf{T}/F_v^+(\mathbf{T}))^*)_{G_v} \xrightarrow{g} \prod_{v \in \Sigma_p} ((\mathbf{T}/F_v^+(\mathbf{T}))^*)_{G_v} \times \prod_{v \in \Sigma - \Sigma_p} (\mathbf{T}^*)_{I_v} \right)^{\vee}. \end{aligned}$$

Hence, the module $\ker(t_{\mathfrak{q}})$ is equal to $(\oplus_{v \in \Sigma} C_v[\mathfrak{q}])^{\vee}$, by definition. On the other hand, $\oplus_{v \in \Sigma} C_v/\mathfrak{q}C_v$ is pseudo-null by assumption, and therefore Lemma 2.2 applied to the module $\oplus_{v \in \Sigma} C_v[\mathfrak{q}]$ completes the proof. \square

Theorem 2.6. *Let $\mathfrak{q} = (g)$ be a principal ideal of Λ_R . Assume that $H^0(F_{\Sigma}/F, \mathbf{A}[\mathfrak{q}])^{\vee}$ is pseudo-null and that the Λ_R -module $C_v/\mathfrak{q}C_v$ ($C_v^{\text{str}}/\mathfrak{q}C_v^{\text{str}}$, respectively) is pseudo-null for each $v \in \Sigma$. Then $\ker(r_{\mathfrak{q}})^{\vee}$ and $\text{coker}(r_{\mathfrak{q}})^{\vee}$ ($\ker(r_{\mathfrak{q}}^{\text{str}})^{\vee}$ and $\text{coker}(r_{\mathfrak{q}}^{\text{str}})^{\vee}$, respectively) are pseudo-null Λ_R -modules.*

Proof. Observe that if $H^0(F_{\Sigma}/F, \mathbf{A}[\mathfrak{q}])^{\vee}$ is pseudo-null the same is true for $H^0(F, \mathbf{A}[\mathfrak{q}])^{\vee}$. The result then follows combining Proposition 2.4 and Proposition 2.5. \square

2.4. Shapiro's Lemma. Let the notation be as in §2.2; thus, F is a number field and F_{∞}/F is a \mathbb{Z}_p -extension, with finite layers F_n , totally ramified at p and unramified outside p . Let T be a finite free R -module equipped with a continuous action of $G_F = \text{Gal}(\bar{F}/F)$ and fix a filtration

$$(3) \quad 0 \longrightarrow F_v^+(T) \longrightarrow T \longrightarrow F_v^-(T) \longrightarrow 0$$

of $G_v = \text{Gal}(\bar{F}_v/F_v)$ -modules, where F_v is the completion of F at v . Denote $F_v(\mu_{p^\infty})/F_v$ be the cyclotomic extension of F_v , where μ_{p^∞} is the p -divisible group of roots of unity in \bar{F}_v . Let Σ_p denote the set of places of F dividing p , and let Σ be a finite set of places of F containing Σ_p ; denote F_{Σ}/F the maximal extension of F which is unramified outside Σ .

Assumption 2.7. We suppose that the following conditions are satisfied.

- (1) T is unramified outside Σ .
- (2) $H^0(F_{\Sigma}/F_n, A)^{\vee}$ is pseudo-null.
- (3) Both $F^+(T)$ and $F^-(T)$ are free R -modules.
- (4) For each $v \mid p$, there are characters $\delta_v, \theta_v : G_v \rightarrow R^{\times}$ such that

- δ_v is unramified and takes the Frobenius Frob_v to $\delta_v(\text{Frob}_v) = u_v$ with $u_v \neq 1$ modulo the maximal ideal \mathfrak{m}_R of R .
- θ_v factors through $G_v \rightarrow \text{Gal}(F_v(\mu_{p^\infty})/F_v)$.
- G_v acts on $F_v^-(T)$ via multiplication by the product $\delta_v \cdot \theta_v$.

Define

$$A = \Phi(T) = T \otimes_R R^\vee.$$

The filtration $F_v^+(T) \subseteq T$ induces a filtration $F_v^+(A) \subseteq A$ of A . For each integer $n \geq 0$ and any prime ideal v of F_n , let $F_{n,v}$ be the completion of F_n at v . Denote $\Sigma_{n,p}$ the set of places of $F_{n,v}$ above p and define

$$\text{Sel}_{\text{str}}(F_n, A) = \ker \left(H^1(F_n, A) \longrightarrow \prod_{v \notin \Sigma_{n,p}} H^1(I_{n,v}, A) \times \prod_{v \in \Sigma_{n,p}} H^1(F_{n,v}, A/F_v^+(A)) \right)$$

and

$$\text{Sel}_{\text{str}}(F_\infty, A) = \varinjlim_n \text{Sel}_{\text{str}}(F_n, A).$$

For any character $\chi : G_\infty \rightarrow B^\times$, where B is a ring, and any B -module M , let $M(\chi)$ denote the B -module M equipped with G_∞ -action given by $g \cdot m = \chi(g)m$. Let $\kappa : G_\infty \rightarrow \Lambda_R^\times$ be the tautological character. Note in particular that $\Lambda_R(\kappa)$ is just Λ_R as Λ_R -module, but we prefer to keep the notation $\Lambda_R(\kappa)$ to stress that we are considering Λ_R as a Λ_R -module and not as a ring. Define the Λ_R -module

$$\mathbf{T} = T \otimes_R \Lambda_R(\kappa^{-1}).$$

Since the extension of rings Λ_R/R is flat (by Lemma 2.1 and [Mat89, Exercise 7.4]) then, tensoring (2) over R with Λ_R we also have a filtration

$$0 \longrightarrow F_v^+(\mathbf{T}) \longrightarrow \mathbf{T} \longrightarrow F_v^-(\mathbf{T}) \longrightarrow 0$$

where $F_v^\pm(\mathbf{T}) = F_v^\pm(T) \otimes_R \Lambda_R(\kappa^{-1})$. Define

$$\mathbf{A} = \Phi(\mathbf{T}) = \mathbf{T} \otimes_{\Lambda_R} \Lambda_R^\vee.$$

We observe that (cf. [Nek06, §2.9.1])

$$\Lambda_R^\vee = \text{Hom}_{\text{cont}}(\Lambda_R, \mathbb{Q}_p/\mathbb{Z}_p) \simeq \text{Hom}_R(\Lambda_R, R^\vee).$$

Moreover, if we stress the structure of Λ_R -modules, we have

$$\Lambda_R^\vee(\kappa) \simeq \text{Hom}_R(\Lambda_R(\kappa^{-1}), R^\vee), \quad \Lambda_R^\vee(\kappa^{-1}) \simeq \text{Hom}_R(\Lambda_R(\kappa), R^\vee).$$

where we use the standard action of Λ_R on $\text{Hom}_R(\Lambda_R, R^\vee)$ given by $(\lambda \cdot \varphi)(x) = \varphi(\lambda^{-1}x)$ for $\lambda \in \Lambda_R$ and $\varphi \in \text{Hom}(\Lambda_R, R^\vee)$.

Note that, since T is a free R -module, we have isomorphisms of Λ_R -modules:

$$\begin{aligned} \mathbf{A} &= \mathbf{T} \otimes_{\Lambda_R} \Lambda_R^\vee \\ &= (T \otimes_R \Lambda_R(\kappa^{-1})) \otimes_{\Lambda_R} \text{Hom}_{\text{cont}}(\Lambda_R(\kappa^{-1}), \mathbb{Q}_p/\mathbb{Z}_p) \\ &= (T \otimes_R \Lambda_R(\kappa^{-1})) \otimes_{\Lambda_R} \text{Hom}_R(\Lambda_R(\kappa^{-1}), R^\vee) \\ &= T \otimes_R \text{Hom}_R(\Lambda_R, R^\vee) \\ &= \text{Hom}_R(\Lambda_R, A) \end{aligned}$$

We now concentrate on ideals \mathfrak{q}_n generated by elements $\omega_n = \gamma^{p^n} - 1$:

$$\mathfrak{q}_n = (\omega_n) = (\gamma^{p^n} - 1),$$

where γ is a topological generator of G_∞ . We have isomorphisms of $\Lambda_R/\mathfrak{q}_n\Lambda_R$ -modules

$$\begin{aligned}\mathbf{A}[\mathfrak{q}_n] &= \mathrm{Hom}_R(\Lambda_R(\kappa), A)[\mathfrak{q}_n] \\ &= \mathrm{Hom}_R(\Lambda_R(\kappa)/\mathfrak{q}_n\Lambda_R(\kappa), A) \\ &\simeq \mathrm{Hom}_R(R[G_n], A)\end{aligned}$$

Lemma 2.8. *For each integer $n \geq 0$ we have $\mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A}[\mathfrak{q}_n]) \simeq \mathrm{Sel}_{\mathrm{str}}(F_n, A)$. Moreover, we have $\mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A}) \simeq \mathrm{Sel}_{\mathrm{str}}(F_\infty, A)$.*

Proof. Shapiro's Lemma shows the the first of the following isomorphism

$$H^1(F_n, A) \simeq H^1(F, \mathrm{Hom}(R[G_n], A)) \simeq H^1(F, \mathbf{A}[\mathfrak{q}_n]),$$

while the second follows from the previous discussion. Taking direct limits over n , we also see that

$$\begin{aligned}H^1(F_\infty, A) &= \varinjlim_n H^1(F_n, A) \\ &\simeq \varinjlim_n H^1(F, \mathrm{Hom}_R(R[G_n], A)) \\ &\simeq H^1(F, \varprojlim_n \mathrm{Hom}_R(R[G_n], A)) \\ &\simeq H^1(F, \mathrm{Hom}_R(\Lambda_R(\kappa), A)) \\ &\simeq H^1(F, \mathbf{A})\end{aligned}$$

where the first and the last isomorphism follow from the previous discussion. We need to show that, under these isomorphisms, $\mathrm{Sel}_{\mathrm{str}}(F_n, A)$ corresponds to $\mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A}[\mathfrak{q}_n])$ and $\mathrm{Sel}_{\mathrm{str}}(F_\infty, A)$ corresponds to $\mathrm{Sel}_{\mathrm{str}}(F, \mathbf{A})$.

Put $C_n(M) = \mathrm{Hom}_R(R[G_n], M)$ for any R -module M . Let Σ_n be the set of places of F_n above places in Σ . We have a commutative diagram:

$$\begin{array}{ccccc}\mathrm{Sel}_{\mathrm{str}}(F_n, A) & \longrightarrow & H^1(F_\Sigma, F_n, A) & \longrightarrow & \prod_{v \in \Sigma_n, v \nmid p} H^1(I_w, A) \times \prod_{v \in \Sigma_n, v \mid p} H^1(F_{n,w}, A/F_w^+(A)) \\ \downarrow r_n & & \downarrow s_n & & \downarrow t_n \\ \mathrm{Sel}_{\mathrm{str}}(F, C_n(A)) & \longrightarrow & H^1(F_\Sigma/F, C_n(A)) & \longrightarrow & \prod_{v \in \Sigma, v \nmid p} H^1(I_v, C_n(A)) \times \prod_{v \in \Sigma, v \mid p} H^1(F_v, C_n(A)/F_v^+(A))\end{array}$$

where $\mathrm{Sel}_{\mathrm{str}}(F, C_n(A))$ is defined by the exactness of the lower horizontal arrow. We claim that the vertical arrow t_n is injective. To show this, note that the map t_n is the product local maps $t_{n,v}$ for all $v \in \Sigma_n$, so we study first these maps $t_{n,v}$. If $w \nmid p$, then $I_w = I_v$ because F_n/F is unramified outside p ; the map $t_{n,v}$ defined by

$$t_{n,v} : \prod_{w|v} H^1(I_w, A) = H^1(I_v, A)^{\sharp w|v} \longrightarrow H^1(I_v, C_n(A)) \simeq H^1(I_v, \mathrm{Hom}_R(R, A))^{\sharp \{w|v\}}.$$

It follows that $t_{n,v}$ is injective. The map $t_{n,v}$ for $v \mid p$ is defined by

$$t_{n,v} : H^1(F_{n,w}, A/F_v^+(A)) \longrightarrow H^1(F_v, \mathrm{Hom}_R(R[G_n], A/F_v^+(A)))$$

which are all isomorphisms by Shapiro's Lemma because, being p totally ramified in the extension F_n/F , we have $\mathrm{Gal}(F_n/F) \simeq G_n$. We therefore conclude that t_n is injective. Since s_n is an isomorphism, the map r_n is an isomorphism too, showing the result. \square

Lemma 2.9. *Let M be an R -module equipped with a G_∞ -action, denote $M_{R\text{-tors}}$ the R -torsion submodule of M and let*

$$N = M_{R\text{-tors}} \otimes_R \Lambda_R(\kappa).$$

Then the quotient $N/(\gamma^{p^n} - 1)N$ is a pseudo-null Λ_R -module for each integer $n \geq 1$.

Proof. Set $I = (\gamma^{p^n} - 1)$ for convenience. The support of N/IN consists of the prime ideals of Λ_R containing I . Fix such a height one prime ideal $\mathfrak{a} = (a)$. Then a is an irreducible factor of $\gamma^{p^n} - 1$. Therefore, $\mathfrak{a} \cap R = 0$. Thus, we have $\mathfrak{m}_R \setminus \{0\} \subseteq (\Lambda_R)_{\mathfrak{a}}^{\times}$. It implies that the localization $(M_{R\text{-tors}})_{\mathfrak{a}}$ of $M_{R\text{-tors}}$ at \mathfrak{a} is trivial. It follows that no height one prime ideal of Λ_R lies in the support of N/IN , and therefore N/IN is pseudo-null over Λ_R . \square

Corollary 2.10. *The Pontryagin duals of the kernel and cokernel of the canonical restriction*

$$\text{res}_{F_{\infty}/F_n} : \text{Sel}_{\text{str}}(F_n, A) \longrightarrow \text{Sel}_{\text{str}}(F_{\infty}, A)^{\text{Gal}(F_{\infty}/F_n)}$$

are pseudo-null Λ_R -modules.

Proof. We only need to check that the assumptions in Theorem 2.6 are satisfied. If so, the result follows by taking $\mathfrak{q}_n = (\gamma^{p^n} - 1)$ in Theorem 2.6, and by using Lemma 2.8 to identify $\text{Sel}_{\text{str}}(F, \mathbf{A}[\mathfrak{q}_n])$ and $\text{Sel}_{\text{str}}(F, \mathbf{A})$ with $\text{Sel}_{\text{str}}(F_n, A)$ and $\text{Sel}_{\text{str}}(F_{\infty}, A)$, respectively.

By Shapiro's Lemma, we have $H^0(F_{\Sigma}/F, \mathbf{A}[\mathfrak{q}_n]) \simeq H^0(F_{\Sigma}/F_n, A)$, and therefore the first assumption in Theorem 2.6 is equivalent to (2) in Assumption 2.7.

We first consider $C_v^{\text{str}}/(\gamma^{p^n} - 1)C_v^{\text{str}}$ for $v \nmid p$. The action of I_v on $\Lambda_R(\kappa^{-1})$ is trivial since all the primes outside p are unramified in F_{∞} . Therefore, $(\mathbf{T}^*)_{I_v} = (T^*)_{I_v} \otimes_R \Lambda_R(\kappa)$, and

$$C_v^{\text{str}} = ((T^*)_{I_v})_{R\text{-tors}} \otimes \Lambda_R(\kappa)$$

where $((T^*)_{I_v})_{R\text{-tors}}$ is the R -torsion submodule of $(T^*)_{I_v}$. Thus, for $v \nmid p$, the statement in the assumption of Theorem 2.6 is equivalent to that

$$((T^*)_{I_v})_{R\text{-tors}} \otimes \Lambda_R(\kappa) / (\gamma^{p^n} - 1)((T^*)_{I_v})_{R\text{-tors}} \otimes \Lambda_R(\kappa)$$

is pseudo-null, which follows from Lemma 2.9 applied to $M = (T^*)_{I_v}$.

We now consider $C_v^{\text{str}}/(\gamma^{p^n} - 1)C_v^{\text{str}}$ for $v \mid p$. Since Λ_R is flat over R , we have

$$(\mathbf{T}/F_v^+(\mathbf{T}))^* = (T/F_v^+(T))^* \otimes_R \Lambda_R(\kappa) = F_v^-(T)^* \otimes_R \Lambda_R(\kappa).$$

We have

$$\begin{aligned} (T/F_v^+(T))^* \otimes_R \Lambda_R(\kappa) &\simeq ((T/F_v^+(T))^* \otimes_R R(\theta_v)) \otimes_R (\Lambda_R(\kappa) \otimes_R R(\theta_v^{-1})) \\ &\simeq ((T/F_v^+(T)) \otimes_R R(\theta_v^{-1}))^* \otimes_R (\Lambda_R(\kappa \cdot \theta_v^{-1})) \\ &\simeq (F_v^-(T) \otimes_R R(\theta_v^{-1}))^* \otimes_R (\Lambda_R(\kappa \cdot \theta_v^{-1})). \end{aligned}$$

The action of I_v on $F_v^-(T) \otimes_R R(\theta_v^{-1})$ is trivial by (4) in Assumption 2.7, and therefore the I_v -coinvariant of $(\mathbf{T}/F_v^+(\mathbf{T}))^*$ is

$$(F_v^-(T) \otimes_R R(\theta_v^{-1}))^* \otimes_R (\Lambda_R(\kappa \cdot \theta_v^{-1}))_{I_v}.$$

Since δ_v is unramified by (4) in Assumption 2.7, the coinvariant of the action of G_v/I_v on $(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*$ is given by

$$\begin{aligned} \frac{(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*}{(\text{Frob}_v - 1)(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*} &\simeq \frac{(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*}{(u_v - 1)(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*} \\ &\simeq \frac{(F_v^-(T) \otimes_R R(\theta_v^{-1}))^*}{((u_v - 1)F_v^-(T) \otimes_R R(\theta_v^{-1}))^*} \end{aligned}$$

By (4) in Assumption 2.7, u_v is not congruent to 1 modulo the maximal ideal of R , so $u_v - 1 \in R^{\times}$, and therefore $(u_v - 1)F_v^-(T) = 0$. Moreover, δ_v acts trivially on $(\Lambda_R(\kappa \cdot \theta_v^{-1}))_{I_v}$. Therefore, the G_v -coinvariant of $(\mathbf{T}/F_v^+(\mathbf{T}))^*$ is trivial, and it follows in particular that the assumption on $C_v^{\text{str}}/(\gamma^{p^n} - 1)C_v^{\text{str}}$ for $v \mid p$ in Theorem 2.6 is satisfied. \square

Lemma 2.11. *Suppose that M is a pseudo-null Λ_R -module. Then for each integer $n \geq 0$, $M/(\gamma^{p^n} - 1)M$ is torsion over $R[G_n] \simeq \Lambda_R/(\gamma^{p^n} - 1)\Lambda_R$.*

Proof. Suppose $M/(\gamma^{p^n} - 1)M$ is not a torsion $R[\Gamma_n]$ -module, and take a copy N of $R[\Gamma_n]$ in $M/(\gamma^{p^n} - 1)M$. Take any height one prime ideal $\mathfrak{a} = (a)$ of Λ_R such that $(a, \gamma^{p^n} - 1) = 1$. Then $N_{\mathfrak{a}} \neq 0$. In particular, $M_{\mathfrak{a}}/(\gamma^{p^n} - 1)M_{\mathfrak{a}} \neq 0$ so $M_{\mathfrak{a}} \neq 0$, which contradicts the assumption that M is a pseudo-null Λ_R -module. \square

Corollary 2.12. *The Pontryagin duals of the kernel and cokernel of the canonical restriction*

$$\mathrm{res}_{F_{\infty}/F_n} : \mathrm{Sel}_{\mathrm{str}}(F_n, A) \longrightarrow \mathrm{Sel}_{\mathrm{str}}(F_{\infty}, A)^{\mathrm{Gal}(F_{\infty}/F_n)}$$

are cotorsion $R[G_n]$ -modules.

Proof. It follows from Corollary 2.10 and Lemma 2.11. \square

3. ANTICYCLOTOMIC IWASAWA THEORY FOR HIDA FAMILIES

3.1. Ordinary families of modular forms. Let $f_0 = \sum_{n=1}^{\infty} a_n q^n \in S_{k_0}(\Gamma_0(Np))$ an ordinary p -stabilized newform (in the sense of [GS93, Def. 2.5]) of weight $k_0 \geq 2$ and trivial nebentypus, defined over a finite extension L/\mathbb{Q}_p . Let $\mathcal{O} = \mathcal{O}_L$ be the valuation ring of L and $a_p \in \mathcal{O}^{\times}$, and f_0 is either a newform of level Np , or arises from a newform of level N . Denote

$$\rho_{f_0} : G_{\mathbb{Q}} := \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \longrightarrow \mathrm{GL}_2(\mathcal{O})$$

the Galois representation associated with f_0 . Since f_0 is ordinary at p , the restriction of ρ_{f_0} to a decomposition group $D_p \subset G_{\mathbb{Q}}$ is upper-triangular. We also denote $k = k_L$ the residue field of L and

$$\bar{\rho}_{f_0} : G_{\mathbb{Q}} \longrightarrow \mathrm{GL}_2(k)$$

the residual representation obtained by reduction modulo the maximal ideal $\mathfrak{m} = \mathfrak{m}_L$ of \mathcal{O} .

Assumption 3.1. The representation $\bar{\rho}_{f_0}$ is absolutely irreducible, and p -distinguished, i.e., writing $\bar{\rho}_{f_0}|_{D_p} \sim \begin{pmatrix} \bar{\varepsilon} & * \\ 0 & \bar{\delta} \end{pmatrix}$, we have $\bar{\varepsilon} \neq \bar{\delta}$.

Let $\mathfrak{h}^{\mathrm{ord}}$ be the Hida ordinary Hecke algebra of tame level $\Gamma_0(N)$, and let \mathcal{R} be the branch of $\mathfrak{h}^{\mathrm{ord}}$ passing through f_0 . If $\Lambda := \mathcal{O}[[\Gamma]]$, where $\Gamma = 1 + p\mathbb{Z}_p$, then \mathcal{R} is a finite flat extension of Λ (the structure of Λ -algebra in $\mathfrak{h}^{\mathrm{ord}}$ is given by the action of diamond operators in Γ). The eigenform f_0 defines an \mathcal{O}_L -algebra homomorphism $\lambda_{f_0} : \mathcal{R} \rightarrow \mathcal{O}$, which is called arithmetic. More generally, an *arithmetic point* of \mathcal{R} is a continuous \mathcal{O}_L -algebra homomorphism $\mathcal{R} \xrightarrow{\kappa} \overline{\mathbb{Q}}_p$ such that the composition

$$\Gamma \longrightarrow \Lambda^{\times} \longrightarrow \mathcal{R} \xrightarrow{\kappa} \overline{\mathbb{Q}}_p^{\times}$$

is given by $\gamma \mapsto \psi(\gamma)\gamma^{k-2}$, for some integer $k \geq 2$ and some finite order character $\psi : \Gamma \rightarrow \overline{\mathbb{Q}}_p^{\times}$. We then say that κ has *weight* k , *character* ψ , and *wild level* p^m , where $m > 0$ is such that $\ker(\psi) = 1 + p^m\mathbb{Z}_p$. Denote by $\mathcal{X}(\mathcal{R})$ the set of continuous \mathcal{O} -algebra homomorphisms from \mathcal{R} into \mathcal{O} , and by $\mathcal{X}_{\mathrm{arith}}(\mathcal{R})$ the subset of $\mathcal{X}(\mathcal{R})$ consisting of arithmetic primes. For each $\kappa \in \mathcal{X}_{\mathrm{arith}}(\mathcal{R})$, let F_{κ} be the residue field of $\ker(\kappa) \subset \mathcal{R}$, which is a finite extension of \mathbb{Q}_p .

For each $n \geq 1$, let $\mathbf{a}_n \in \mathcal{R}$ be the image of $T_n \in \mathfrak{h}^{\mathrm{ord}}$ under the natural projection $\mathfrak{h}^{\mathrm{ord}} \rightarrow \mathcal{R}$, and form the q -expansion

$$\mathbf{f} = \sum_{n=1}^{\infty} \mathbf{a}_n q^n \in \mathcal{R}[[q]].$$

By [Hid86, Thm. 1.2], if $\kappa \in \mathcal{X}_{\mathrm{arith}}(\mathcal{R})$ is an arithmetic prime of weight $k \geq 2$, character ψ , and wild level p^m , then

$$f_{\kappa} := \sum_{n=1}^{\infty} \kappa(\mathbf{a}_n) q^n \in F_{\kappa}[[q]]$$

is (the q -expansion of) an ordinary p -stabilized newform in $S_k(\Gamma_0(Np^m), \omega^{k_0-k}\psi)$ of level $\Gamma_0(Np^n)$, character $\omega^{k_0-k}\psi$ and weight k , where $\omega : (\mathbb{Z}/p\mathbb{Z})^{\times} \rightarrow \mathbb{Z}_p^{\times}$ is the Teichmüller character.

3.2. Critical characters. Following [How07, Def. 2.1.3], factor the p -adic cyclotomic character as

$$\varepsilon_{\text{cyc}} = \varepsilon_{\text{tame}} \cdot \varepsilon_{\text{wild}} : G_{\mathbb{Q}} \longrightarrow \mathbb{Z}_p^{\times} \simeq \boldsymbol{\mu}_{p-1} \times \Gamma,$$

and define the *critical character* $\Theta : G_{\mathbb{Q}} \rightarrow \mathcal{R}^{\times}$ by

$$(4) \quad \Theta(\sigma) = \varepsilon_{\text{tame}}^{\frac{k_0-2}{2}}(\sigma) \cdot [\varepsilon_{\text{wild}}^{1/2}(\sigma)],$$

where $\varepsilon_{\text{tame}}^{\frac{k_0-2}{2}} : G_{\mathbb{Q}} \rightarrow \boldsymbol{\mu}_{p-1}$ is any fixed choice of square-root of $\varepsilon_{\text{tame}}^{k_0-2}$ (see [How07, Rem. 2.1.4]), $\varepsilon_{\text{wild}}^{1/2} : G_{\mathbb{Q}} \rightarrow \Gamma$ is the unique square-root of $\varepsilon_{\text{wild}}$ taking values in Γ , and $[\cdot] : \Gamma \rightarrow \Lambda^{\times} \rightarrow \mathcal{R}^{\times}$ is the map given by the inclusion as group-like elements.

Define the character $\theta : \mathbb{Z}_p^{\times} \rightarrow \mathcal{R}^{\times}$ by the relation $\Theta = \theta \circ \varepsilon_{\text{cyc}}$, and for each $\kappa \in \mathcal{X}_{\text{arith}}(\mathcal{R})$, let $\theta_{\kappa} : \mathbb{Z}_p^{\times} \rightarrow \overline{\mathbb{Q}}_p^{\times}$ be the composition of θ with κ . If κ has weight $k \geq 2$ and character ψ , then

$$(5) \quad \theta_{\kappa}^2(z) = z^{k-2} \omega^{k_0-k} \psi(z)$$

for all $z \in \mathbb{Z}_p^{\times}$.

3.3. p -adic L -functions. Let K/\mathbb{Q} be an imaginary quadratic field of discriminant prime to Np . Write $N = N^+N^-$, where all primes dividing N^+ are split in K , and all primes dividing N^- are inert in K . We will work under the following

- Assumption 3.2.**
- (1) N^- is a square-free product of an odd number of distinct primes.
 - (2) The residual representation $\bar{\rho}_{f_0}$ is ramified at all primes $\ell \mid N^-$.
 - (3) $a_p \not\equiv \pm 1$ modulo the maximal ideal of \mathcal{O} (we say that p is a *non-anomalous prime* for $\bar{\rho}_{f_0}$ in this case).
 - (4) p is split in K .

Let B be the definite quaternion algebra over \mathbb{Q} of discriminant N^- . For each prime $\ell \nmid N^-$, fix isomorphisms $\iota_{\ell} : B \otimes_{\mathbb{Q}} \mathbb{Q}_{\ell} \simeq \text{M}_2(\mathbb{Q}_{\ell})$. Let $m \mapsto R_m$, for $m \geq 0$ an integer, be the sequence of Eichler orders of level N^+p^m , defined by the condition that $\iota_{\ell}(R_m \otimes_{\mathbb{Z}} \mathbb{Z}_{\ell})$ consists of the matrices in $\text{M}_2(\mathbb{Z}_{\ell})$ which are upper triangular modulo $\ell^{\text{val}_{\ell}(N^+p^m)}$ for all primes $\ell \nmid N^-$ (thus, in particular, $R_{m+1} \subseteq R_m$ for all integers $m \geq 0$). For a ring A , denote \hat{A} its profinite completion. Let $U_m \subset \hat{R}_m^{\times}$ be the compact open subgroup defined by

$$U_m := \left\{ (x_q)_q \in \hat{R}_m^{\times} \mid i_p(x_p) \equiv \begin{pmatrix} 1 & * \\ 0 & * \end{pmatrix} \pmod{p^m} \right\}.$$

Consider the double coset spaces

$$\tilde{X}_m(K) = B^{\times} \backslash (\text{Hom}_{\mathbb{Q}}(K, B) \times \hat{B}^{\times}) / U_m,$$

where $b \in B^{\times}$ act on left on $(\Psi, g) \in \text{Hom}_{\mathbb{Q}}(K, B) \times \hat{B}^{\times}$ by $b \cdot (\Psi, g) = (bgb^{-1}, bg)$, and U_m acts on \hat{B}^{\times} by right multiplication. The space $\tilde{X}_m(K)$ is equipped with a nontrivial Galois action defined as follows: If $\sigma \in \text{Gal}(K^{\text{ab}}/K)$ and $P \in \tilde{X}_m(K)$ is the class of a pair (Ψ, g) , then $P^{\sigma} := [(\Psi, g\hat{\Psi}(a))]$, where $a \in K^{\times} \backslash \hat{K}^{\times}$ is such that $\text{rec}_K(a) = \sigma$, and we extend this to an action of G_K by letting each $\sigma \in G_K$ act on $\tilde{X}_m(K)$ as $\sigma|_{K^{\text{ab}}}$. The space $\tilde{X}_m(K)$ is also equipped with standard action of Hecke operators T_{ℓ} for $\ell \nmid Np$, U_p and diamond operators $\langle d \rangle$ for $d \in \mathbb{Z}_p^{\times}$.

Let $D_m := \text{Div}(\tilde{X}_m) \otimes \mathcal{O}_L$ be the divisor group of \tilde{X}_m and denote $\alpha_m : D_m \rightarrow D_{m-1}$ the canonical projection. Passing to the ordinary part D_m^{ord} and tensoring with the primitive component \mathcal{R} gives Hecke modules \mathbf{D}_m (for $m \geq 0$) and, twisting the Galois action by Θ^{-1} , Hecke modules \mathbf{D}_m^{\dagger} . The analogous Hecke modules obtained from the inverse limits of the divisor group D_m (with respect to the canonical projection maps α_m) are the Hecke modules denoted \mathbf{D} and \mathbf{D}^{\dagger} in [LV11, §6.4]. Let e^{ord} denote the ordinary projector. Denote $\text{Pic}(\tilde{X}_m)$ the

Picard group of \tilde{X}_m . Define the Hecke modules $J_m^{\text{ord}} := e^{\text{ord}}(\text{Pic}(\tilde{X}_m) \otimes_{\mathbb{Z}} \mathcal{O}_L)$, $\mathbf{J}_m := J_m^{\text{ord}} \otimes_{\mathfrak{h}^{\text{ord}}} \mathcal{R}$ and $\mathbf{J}_m^{\dagger} := \mathbf{J}_m \otimes_{\mathcal{R}} \mathcal{R}^{\dagger}$. Finally define $\mathbf{J}^{\dagger} := \varprojlim_m \mathbf{J}_m^{\dagger}$. The projections $\text{Div}(\tilde{X}_m) \rightarrow \text{Pic}(\tilde{X}_m)$ induce a map

$$\lambda : \mathbf{D}^{\dagger} \longrightarrow \mathbf{J}^{\dagger}.$$

Thanks to Assumptions 3.1 and 3.2, we have $\dim_{k_{\mathcal{R}}}(\mathbf{J}^{\dagger}/\mathfrak{m}_{\mathcal{R}}\mathbf{J}^{\dagger}) = 1$ by [CKL17, Theorem 3.1]; here, $\mathfrak{m}_{\mathcal{R}}$ is the maximal ideal of \mathcal{R} , and $k_{\mathcal{R}} := \mathcal{R}/\mathfrak{m}_{\mathcal{R}}$ is its residue field. By [LV11, Prop. 9.3], we conclude that the module \mathbf{J}^{\dagger} is free of rank one over \mathcal{R} . Fix an isomorphism

$$\eta : \mathbf{J}^{\dagger} \simeq \mathcal{R}.$$

Let K_{∞} be the anticyclotomic \mathbb{Z}_p -extension of K , and define $\Gamma_{\infty} = \text{Gal}(K_{\infty}/K) \simeq \mathbb{Z}_p$. Denote K_n the subfield of K_{∞} such that $\Gamma_n = \text{Gal}(K_n/K) \simeq \mathbb{Z}/p^n\mathbb{Z}$. Define

$$\Lambda_{\mathcal{R}} = \mathcal{R}[[\Gamma_{\infty}]] = \varprojlim_n \mathcal{R}[\Gamma_n].$$

The paper [LV11] introduces for each integer $n \geq 0$ a sequence $m \mapsto \tilde{P}_{p^n, m}$ of Gross-Heegner points in $\tilde{X}_m(K)$ of conductor p^{m+n} ; these points satisfy norm-relations and allows to construct big theta elements $\Theta_n(\mathbf{f}) \in \mathbf{D}[\Gamma_n]$ by an inverse limit procedure inverting the U_p operator; we will view $\Theta_n(\mathbf{f})$ as elements in $\mathcal{R}[\Gamma_n]$ by means of the map $\mathbf{D} \xrightarrow{\lambda} \mathbf{J} \xrightarrow{\eta} \mathcal{R}$. The elements $\Theta_n(\mathbf{f})$ are compatible under the natural maps $\mathcal{R}[\Gamma_m] \rightarrow \mathcal{R}[\Gamma_n]$ for all $m \geq n$, thus defining an element $\Theta_{\infty}(\mathbf{f}) := \varprojlim_n \Theta_n(\mathbf{f})$ in the completed group ring $\Lambda_{\mathcal{R}}$.

Definition 3.3. The *two-variable p -adic L -function* attached \mathbf{f} and K is the element

$$L_p(\mathbf{f}/K) := \Theta_{\infty}(\mathbf{f}) \cdot \Theta_{\infty}(\mathbf{f})^* \in \Lambda_{\mathcal{R}},$$

where $x \mapsto x^*$ is the involution on $\mathcal{R}[[\Gamma_{\infty}]]$ given by $\gamma \mapsto \gamma^{-1}$ on group-like elements.

3.4. Selmer groups of Hida families. Let \mathbf{T} be Hida's big Galois representation associated with \mathcal{R} . Then \mathbf{T} is a free \mathcal{R} -module of rank 2, equipped with a continuous action of $G_{\mathbb{Q}} = \text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ and a filtration of $\mathcal{R}[G_{\mathbb{Q}_p}]$ -modules

$$0 \longrightarrow F_v^+(\mathbf{T}) \longrightarrow \mathbf{T} \longrightarrow F_v^-(\mathbf{T}) \longrightarrow 0$$

where $G_{\mathbb{Q}_p} = \text{Gal}(\bar{\mathbb{Q}}_p/\mathbb{Q}_p)$ is a decomposition group of $G_{\mathbb{Q}}$ at p . Both $F_v^+(\mathbf{T})$ and $F_v^-(\mathbf{T})$ are free \mathcal{R} -modules of rank 1; G_v acts on $F_v^-(\mathbf{T})$ via the unramified character $\eta_v : G_v/I_v \rightarrow \mathcal{R}^{\times}$ which takes the arithmetic Frobenius to U_p , and G_v acts on $F_v^+(\mathbf{T})$ via $\eta_v^{-1}\varepsilon_{\text{cyc}}[\varepsilon_{\text{cyc}}]$.

Denote $\mathbf{T}^{\dagger} = \mathbb{T} \otimes \Theta^{-1}$ the critical twist of \mathbf{T} corresponding to the choice of the critical character Θ chosen in (4). For each arithmetic point, define $F_{\kappa} = \mathcal{R}_{\kappa}/\ker(\kappa)\mathcal{R}_{\kappa}$, where \mathcal{R}_{κ} is the localisation of \mathcal{R} at κ . Then $V_{\kappa}^{\dagger} = \mathbf{T}^{\dagger} \otimes_{\mathcal{R}} F_{\kappa}$ is isomorphic to the self-dual twist of Deligne representation $V_{f_{\kappa}}$ attached to the eigenform f_{κ} . If $\mathfrak{p} = \mathfrak{p}_{\kappa} = \ker(\kappa)$, we also denote \mathcal{R}_{κ} by $\mathcal{R}_{\mathfrak{p}}$ and V_{κ}^{\dagger} by $V_{\mathfrak{p}}^{\dagger}$. Moreover, we have a filtration $\mathcal{R}[G_{\mathbb{Q}_p}]$ -modules

$$0 \longrightarrow F_v^+(\mathbf{T}^{\dagger}) \longrightarrow \mathbf{T}^{\dagger} \longrightarrow F_v^-(\mathbf{T}^{\dagger}) \longrightarrow 0$$

where G_v acts on $F_v^-(\mathbf{T}^{\dagger})$ via the character $\eta_v\Theta^{-1}$ and G_v acts on $F_v^+(\mathbf{T}^{\dagger})$ via $\eta_v^{-1}\Theta^{-1}\varepsilon_{\text{cyc}}[\varepsilon_{\text{cyc}}]$. Let

$$\mathbf{A}^{\dagger} = \Phi(\mathbf{T}^{\dagger}) = \mathbf{T}^{\dagger} \otimes_{\mathcal{R}} \mathcal{R}^{\vee}.$$

As in §2.2 we introduce strict Greenberg Selmer groups $\text{Sel}_{\text{str}}(K_n, \mathbf{A}^{\dagger})$ and $\text{Sel}_{\text{str}}(K_{\infty}, \mathbf{A}^{\dagger})$ and Selmer groups $\text{Sel}(K_n, \mathbf{A}^{\dagger})$ and $\text{Sel}(K_{\infty}, \mathbf{A}^{\dagger})$. Under our assumptions, by [CKL17, Theorem 4.1], we know that $\text{Sel}_{\text{str}}(K_n, \mathbf{A}^{\dagger}) \simeq \text{Sel}(K_n, \mathbf{A}^{\dagger})$ and $\text{Sel}_{\text{str}}(K_{\infty}, \mathbf{A}^{\dagger}) \simeq \text{Sel}(K_{\infty}, \mathbf{A}^{\dagger})$. We may also consider Nekovář extended Selmer groups $\tilde{H}_f^1(K_n, \mathbf{A}^{\dagger})$ and $\tilde{H}_f^1(K_{\infty}, \mathbf{A}^{\dagger})$. By [Nek06, Lemma 9.6.3] we have an exact sequence

$$H^0(K_n, \mathbf{A}^{\dagger}) \longrightarrow \tilde{H}_f^1(K_n, \mathbf{A}^{\dagger}) \longrightarrow \text{Sel}_{\text{str}}(K_n, \mathbf{A}^{\dagger}) \longrightarrow 0.$$

Lemma 3.4. $H^0(K_n, \mathbf{A}^\dagger) = 0$.

Proof. Let $M = H^0(K_n, \mathbf{A}^\dagger)^\vee$ be the Pontryagin dual of $H^0(K_n, \mathbf{A}^\dagger)$. By the topological Nakayama's Lemma, it is enough to show that $M/\mathfrak{m}_{\mathcal{R}}M = 0$, where $\mathfrak{m}_{\mathcal{R}}$ is the maximal ideal of \mathcal{R} . For this, taking again Pontryagin duals, it is enough to show that

$$H^0(K_n, \mathbf{A}^\dagger)[\mathfrak{m}_{\mathcal{R}}] = H^0(K_n, \mathbf{A}^\dagger[\mathfrak{m}_{\mathcal{R}}]) = 0.$$

Now the Galois representation $\mathbf{A}^\dagger[\mathfrak{m}_{\mathcal{R}}]$ is isomorphic to $\bar{\rho}_{f_0}$, which is irreducible by assumption, and it follows from standard arguments (*e.g.* [LV17, Lemmas 3.9, 3.10]) that the K_n -invariants of $\mathbf{A}^\dagger[\mathfrak{m}_{\mathcal{R}}]$ are trivial. \square

It follows from Lemma 3.4 that $\tilde{H}_f^1(K_n, \mathbf{A}^\dagger) \simeq \text{Sel}_{\text{str}}(K_n, \mathbf{A}^\dagger)$. Thus, summing up, we have

$$(6) \quad \text{Sel}_{\text{str}}(K_n, \mathbf{A}^\dagger) \simeq \text{Sel}(K_n, \mathbf{A}^\dagger) \simeq \tilde{H}_f^1(K_n, \mathbf{A}^\dagger)$$

and, taking direct limits with respect to the canonical restriction maps,

$$(7) \quad \text{Sel}_{\text{str}}(K_\infty, \mathbf{A}^\dagger) \simeq \text{Sel}(K_\infty, \mathbf{A}^\dagger) \simeq \tilde{H}_{f, \text{Iw}}^1(K_\infty, \mathbf{A}^\dagger) = \varinjlim_n \tilde{H}_f^1(K_n, \mathbf{A}^\dagger).$$

3.5. Control theorems for Hida representations. Let I_n be the kernel of the map $\Lambda \rightarrow \mathcal{O}$ which takes the topological generator γ of Γ_∞ to $\gamma^{p^n} - 1$. For an integer $n \geq 0$, define

$$\Delta_n = \text{Gal}(K_\infty/K_n).$$

In particular, we have $\Gamma_\infty/\Delta_n \simeq \Gamma_n$.

Theorem 3.5. *The kernel and cokernel of the map*

$$\tilde{H}_f^1(K_n, \mathbf{A}^\dagger) \longrightarrow \tilde{H}_{f, \text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^{\Delta_n}$$

are cotorsion $\Lambda_{\mathcal{R}}/I_n\Lambda_{\mathcal{R}} \simeq \mathcal{R}[\Gamma_n]$ -modules.

Proof. This follows from Corollary 2.12 and (6), (7) once we check that Assumption 2.7 of Corollary 2.10 are satisfied for $T = \mathbf{T}^\dagger$ and $R = \mathcal{R}$ in Assumption 2.7. We know that \mathbf{T}^\dagger is free of rank 2 over \mathcal{R} , and is unramified over the set of places Σ dividing Np ; moreover, $F_v^+(\mathbf{T}^\dagger)$ and $F_v^-(\mathbf{T}^\dagger)$ are free of rank 1 over \mathcal{R} , so both (1) and (3) are satisfied. For (2) we need to check that $H^0(K_\Sigma/K_n, \mathbf{A}^\dagger)$ is a pseudo-null $\Lambda_{\mathcal{R}}$ -module. Since \mathbf{A}^\dagger is unramified outside Σ , the Galois group $\text{Gal}(\mathbb{Q}/K_\Sigma)$ acts trivially on \mathbf{A}^\dagger , so $H^0(K_\Sigma/K_n, \mathbf{A}^\dagger) = H^0(K_n, \mathbf{A}^\dagger)$, which is trivial by Lemma 3.4. Condition (2) is guaranteed by the fact that p is non-anomalous in Assumption 3.2, after taking $\delta_v = \eta_v^{-1}$ and $\theta_v = \Theta^{-1}\varepsilon_{\text{cyc}}[\varepsilon_{\text{cyc}}]$, noting that θ_v factors through the cyclotomic \mathbb{Z}_p -extension of K . \square

4. PROOFS OF THE MAIN RESULTS

The following result proves [LV11, Conjecture 9.12], a definite version of the two-variable Iwasawa main conjecture for Hida families in the anticyclotomic context.

Theorem 4.1. *Suppose Assumptions 3.1 and 3.2 are satisfied, and that the Hida family \mathbf{f} admits a specialisation f_k of weight $k \equiv 2 \pmod{p-1}$ and trivial nebentypus. Then the group $\tilde{H}_{f, \text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)$ is a finitely generated cotorsion $\Lambda_{\mathcal{R}}$ -module and there is an equality*

$$(L_p(\mathbf{f}/K)) = \text{Char}_{\Lambda_{\mathcal{R}}} \left(H_{f, \text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee \right)$$

of ideals in $\Lambda_{\mathcal{R}}$.

Proof. That $\tilde{H}_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)$ is finitely generated follows easily from the topological Nakayama’s Lemma. The proof of [CKL17, Theorem 5.3] shows the inclusion of the characteristic ideal in the ideal generated by the p -adic L -function (see in particular the last displayed equation in the proof of [CKL17, Theorem 5.3]). More precisely, by [KL22, Theorem 11.1] we know that $L_p(\mathbf{f}/K)$ is equal, up to units in \mathbb{L} , to the self-dual twist of the restriction of Skinner–Urban’s three-variable p -adic L -function to the anticyclotomic line (see [KL22, §4.4]). Combining [SU14, Theorem 3.26] and [Rub11, Lemma 1.2], we see that the inclusion of $\text{Char}_{\Lambda_{\mathcal{R}}}\left(H_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee\right)$ in $(L_p(\mathbf{f}/K))$ holds. To get the equality, it suffices to establish equality for some classical specialisation, which follows in our setting from [CKL17, Corollary 3]. Finally, since $L_p(\mathbf{f}/K) \neq 0$, it follows that $H_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)$ is $\Lambda_{\mathcal{R}}$ -cotorsion. \square

As a corollary of Theorem 4.1, we obtain a result in the direction of [LV11, Conjecture 9.5], a definite version of the horizontal non-vanishing conjecture of Howard [How07, Conjecture 3.4.1]. Denote $\chi_{\text{triv}} : \mathcal{R}[[\Gamma_\infty]] \rightarrow \mathcal{R}$ the morphism associate with the trivial character of Γ_∞ , and define

$$(8) \quad \mathcal{J}_0 = \chi_{\text{triv}}(\Theta_\infty(\mathbf{f})).$$

Corollary 4.2. *Let the assumptions be as in Theorem 4.1. If $\tilde{H}_f^1(K, \mathbf{T}^\dagger)$ is a torsion \mathcal{R} module, then $\mathcal{J}_0 \neq 0$.*

Proof. Since $\tilde{H}_f^1(K, \mathbf{T}^\dagger)$ is a torsion \mathcal{R} -module, it follows from [LV14, Corollary 5.5] that $\tilde{H}_f^1(K, V_{f_\kappa}^\dagger) = 0$ for all but finitely many arithmetic character κ , where $\tilde{H}_f^1(K, V_{f_\kappa}^\dagger)$ is the extended Bloch–Kato Selmer group of $V_{f_\kappa}^\dagger$. By [Nek06, Proposition 12.7.13.4(i)], this implies that $\tilde{H}_f^2(K, \mathbf{T}^\dagger)$ is a torsion \mathcal{R} -module. Poitou–Tate global duality [Nek06, §0.1] implies then that $H_f^1(K, \mathbf{A}^\dagger)^\vee$ is also a torsion \mathcal{R} -module.

Let I be the kernel of χ_{triv} . By Theorem 3.5, the kernel and cokernel of the map

$$H_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee / IH_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee \longrightarrow H_f^1(K, \mathbf{A}^\dagger)^\vee$$

are torsion \mathcal{R} -modules. Since $H_f^1(K, \mathbf{A}^\dagger)^\vee$ is a torsion \mathcal{R} -module, it follows that

$$H_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee / IH_{f,\text{Iw}}^1(K_\infty, \mathbf{A}^\dagger)^\vee$$

is also a torsion \mathcal{R} -module, and its characteristic power series is then a non-zero element of \mathcal{R} . By Theorem 4.1 we then have $L_p(\mathbf{f}/K)(\chi_{\text{triv}}) \neq 0$. The result follows now from Definition 3.3 and (8). \square
