May 2022

**Abstract.** We consider the Hermitian Eisenstein series  $E_k^{(\mathbb{K})}$  of degree 2 and weight  $k$  associated with an imaginary-quadratic number field  $\mathbb{K}$  and determine the influence of  $\mathbb{K}$  on the arithmetic and the growth of its Fourier coefficients. We find that they satisfy the identity  $E_4^{(\mathbb{K})^2} = E_8^{(\mathbb{K})}$ , which is well-known for Siegel modular forms of degree 2, if and only if  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$ . As an application, we show that the Eisenstein series  $E_k^{(\mathbb{K})}$ ,  $k = 4, 6, 8, 10, 12$  are algebraically independent whenever  $\mathbb{K} \neq \mathbb{Q}(\sqrt{-3})$ . The difference between the Siegel and the restriction of the Hermitian to the Siegel half-space is a cusp form in the Maaß space that does not vanish identically for sufficiently large weight; however, when the weight is fixed, we will see that it tends to 0 as the discriminant tends to  $-\infty$ . Finally, we show that these forms generate the space of cusp forms in the Maaß Spezialschar as a module over the Hecke algebra as  $\mathbb{K}$  varies over imaginary-quadratic number fields.

**Keywords:** Hermitian Eisenstein series, Siegel Eisenstein series, Maaß space

**Classification MSC 2020:** 11F46, 11F55

# 1 Introduction

Eisenstein series are the most common examples of modular forms in several variables. In the case of Hermitian modular forms associated with an imaginary-quadratic number field  $\mathbb{K}$ , they were introduced by H. Braun [2]. In this paper we consider Hermitian Eisenstein series of degree 2. Its Fourier expansion is determined by the Maaß condition and has been worked out explicitly (cf. [16], [10]).

This knowledge leads to new insights on the influence of  $\mathbb{K}$  on the arithmetic and the growth of the Fourier coefficients. We will demonstrate that the Eisenstein series  $E_k^{(\mathbb{K})}$  satisfy the identity  $E_4^{(\mathbb{K})^2} = E_8^{(\mathbb{K})}$ , whose analogue for Siegel modular forms of degree 2 is well known, if and only if  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$ . This allows us to show that the Eisenstein series  $E_k^{(\mathbb{K})}$ ,  $k = 4, 6, 8, 10, 12$ , are algebraically independent whenever  $\mathbb{K} \neq \mathbb{Q}(\sqrt{-3})$ .

Finally we consider the difference between  $E_k^{(\mathbb{K})}$  restricted to the Siegel half-space and the Siegel Eisenstein series of weight  $k$ . This is a Siegel cusp form in the Maaß space. When the weight  $k$  is fixed, its limit is 0 as the discriminant of  $\mathbb{K}$  tends to  $-\infty$ . On the other hand, it does not vanish identically whenever the weight is sufficiently large. Moreover the vanishing of the above difference can be characterized by the vanishing of a Shimura lift. This allows us to show that the subspace of cusp forms in the Maaß space is generated by these restrictions as a module over the Hecke algebra, when  $\mathbb{K}$  varies over all imaginary-quadratic number fields.

## 2 An identity in weight 8

The *Hermitian half-space*  $\mathbb{H}_2$  and the *Siegel half-space*  $\mathbb{S}_2$  of degree 2 are given by

$$\mathbb{H}_2 := \left\{ Z \in \mathbb{C}^{2 \times 2}; \frac{1}{2i}(Z - \overline{Z}^{tr}) > 0 \right\} \supset \mathbb{S}_2 := \{ Z \in \mathbb{H}_2; Z = Z^{tr} \}.$$

Throughout the paper we let  $\mathbb{K}$  be an imaginary-quadratic number field of discriminant  $\Delta = \Delta_{\mathbb{K}}$  with ring of integers  $\mathcal{O}_{\mathbb{K}}$  and inverse different  $\mathcal{O}_{\mathbb{K}}^{\sharp} = \mathcal{O}_{\mathbb{K}}/\sqrt{\Delta_{\mathbb{K}}}$ . If  $D$  is a fundamental discriminant, let  $\chi_D$  denote the associated Dirichlet character; in particular,  $\chi_{\mathbb{K}} = \chi_{\Delta}$ . The *Hermitian modular group* of degree 2 is

$$\Gamma_2^{(\mathbb{K})} := \left\{ M \in \mathcal{O}_{\mathbb{K}}^{4 \times 4}; \overline{M}^{tr} J M = J, \det M = 1 \right\}, \quad J = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}, \quad I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Then

$$\Gamma_2 := \Gamma_2^{(\mathbb{K})} \cap \mathbb{R}^{4 \times 4}$$

is the *Siegel modular group* of degree 2. The space  $\mathcal{M}_k(\Gamma_2^{(\mathbb{K})})$  of Hermitian modular forms of weight  $k$  consists of all holomorphic functions  $F : \mathbb{H}_2 \rightarrow \mathbb{C}$  satisfying

$$F((AZ + B)(CZ + D)^{-1}) = \det(CZ + D)^k F(Z) \quad \text{for all } \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \Gamma_2^{(\mathbb{K})}.$$

Any such  $F$  has a Fourier expansion of the form

$$F(Z) = \sum_{T \in \Lambda_2, T \geq 0} \alpha_F(T) e^{2\pi i \operatorname{trace}(TZ)},$$

where

$$\Lambda_2 = \left\{ T = \begin{pmatrix} n & t \\ \bar{t} & m \end{pmatrix}; m, n \in \mathbb{N}_0, t \in \mathcal{O}_{\mathbb{K}}^{\#} \right\}.$$

If  $\varepsilon(T) := \max\{\ell \in \mathbb{N}; \frac{1}{\ell}T \in \Lambda_2\}$  for  $T \neq 0$ , we can define the Hermitian Eisenstein series of even weight  $k \geq 4$  due to [16] and [10] as a Maaß lift via

$$(1) \quad E_k^{(\mathbb{K})}(Z) = 1 + \sum_{0 \neq T \in \Lambda_2, T \geq 0} \sum_{d|\varepsilon(T)} d^{k-1} \alpha_k^*(|\Delta| \det T/d^2) e^{2\pi i \operatorname{trace}(TZ)}, \quad Z \in \mathbb{H}_2,$$

where  $\alpha_k^* = \alpha_{k,\Delta}^*$  is given by

$$(2) \quad \alpha_k^*(\ell) = \begin{cases} 0, & \text{if } \ell \neq 0, a_{\Delta}(\ell) = 0, \\ -2k/B_k, & \text{if } \ell = 0, \\ r_{k,\Delta} \sum_{t|\ell} \varepsilon_{t,\ell}^{(\Delta)} (\ell/t)^{k-2}, & \text{if } \ell > 0, a_{\Delta}(\ell) \neq 0, \end{cases}$$

where

$$(3) \quad r_{k,\Delta} = \frac{-4k(k-1)}{B_k B_{k-1,\chi}} > 0,$$

$$\varepsilon_{t,\ell}^{(\Delta)} = \frac{1}{a_{\Delta}(\ell)} \sum_{\substack{D_1 D_2 = \Delta \\ D_j \text{ fund. discr.}}} \chi_{D_1}(t) \chi_{D_2}(-\ell/t),$$

$$a_{\Delta}(\ell) = \#\{u : \mathcal{O}_{\mathbb{K}}^{\#}/\mathcal{O}_{\mathbb{K}}; \Delta u \bar{u} \equiv \ell \pmod{\Delta}\} = \prod_{j=1}^r (1 + \chi_j(-\ell)),$$

if  $\Delta = \Delta_1 \cdots \Delta_r$  is the decomposition into prime discriminants and  $\chi_j = \chi_{\Delta_j}$ . If  $\ell \in \mathbb{N}$  and  $a_{\Delta}(\ell) > 0$ , then any  $t \mid \ell$  satisfies

$$(4) \quad \varepsilon_{t,\ell}^{(\Delta)} = \prod_{j=1}^r \frac{\chi_j(t) + \chi_j(-\ell/t)}{1 + \chi_j(-\ell)}$$

$$= \prod_{j:\gcd(t,\Delta_j)=1} \chi_j(t) \cdot \prod_{j:\gcd(t,\Delta_j)>1} \chi_j(-\ell/t).$$

If  $k > 4$  is even, we have the absolutely convergent series

$$E_k^{(\mathbb{K})}(Z) = \sum_{\begin{pmatrix} A & B \\ C & D \end{pmatrix} : \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \backslash \Gamma_2^{(\mathbb{K})}} \det(CZ + D)^{-k}, \quad Z \in \mathbb{H}_2.$$

We derive a first result on the growth and the arithmetic of the Fourier coefficients depending on  $\mathbb{K}$ .

**Theorem 1.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field and let  $k \geq 4$  be even. Then*

$$a) \quad \varepsilon_{t,\ell}^{(\Delta)} = \chi_{D'_t}(t)\chi_{D_t}(-\ell/t)$$

*holds for all  $t|\ell$ ,  $\ell \in \mathbb{N}$ ,  $a_\Delta(\ell) > 0$ , where  $D_t, D'_t$  are fundamental discriminants satisfying  $D_t D'_t = \Delta$ ,  $|D_t| = \gcd(t^\infty, \Delta)$ .*

$$b) \quad 0 < r_{k,\Delta}(2 - \zeta(k-2))\ell^{k-2} \leq \alpha_{k,\Delta}^*(\ell) \leq r_{k,\Delta}\zeta(k-2)\ell^{k-2}$$

*holds for all  $\ell \in \mathbb{N}$  with  $a_\Delta(\ell) > 0$ .*

*c) One has*

$$\begin{aligned} 0 &< \frac{(2\pi)^{2k-1}}{\zeta(k-1)\zeta(k)(k-2)!(k-1)!} \cdot \frac{1}{|\Delta|^{k-3/2}} \\ &\leq r_{k,\Delta} \leq \frac{(2\pi)^{2k-1}}{(2 - \zeta(k-1))\zeta(k)(k-2)!(k-1)!} \cdot \frac{1}{|\Delta|^{k-3/2}}. \end{aligned}$$

*d) If  $\ell_1, \ell_2 \in \mathbb{N}$  are coprime with  $a_\Delta(\ell_j) > 0$  and  $\gcd(\ell_1\ell_2, \Delta) = 1$ , then*

$$\alpha_{k,\Delta}^*(\ell_1) \cdot \alpha_{k,\Delta}^*(\ell_2) = r_{k,\Delta} \cdot \alpha_{k,\Delta}^*(\ell_1\ell_2).$$

*Proof.* We observe that

$$\operatorname{sgn}(B_k B_{k-1,\chi}) = \chi_{\mathbb{K}}(-1) = -1,$$

$$(5) \quad |B_k| = \frac{2k!\zeta(k)}{(2\pi)^k},$$

$$(6) \quad \frac{2(k-1)!|\Delta|^{k-3/2}}{(2\pi)^{k-1}}(2 - \zeta(k-1)) \leq |B_{k-1,\chi}| \leq \frac{2(k-1)!|\Delta|^{k-3/2}}{(2\pi)^{k-1}}\zeta(k-1),$$

$$\varepsilon_{t,\ell}^{(\Delta)} = \chi_{\mathbb{K}}(t), \quad \text{if } \gcd(t, \Delta) = 1.$$

Then the claim follows from (2), (3) and (4). □

Inserting estimates for the Riemann zeta function we get

$$(7) \quad \begin{aligned} \frac{8\,792}{\sqrt{|\Delta|}} &\leq \alpha_4^*(|\Delta|) \leq \frac{61\,362}{\sqrt{|\Delta|}}, \\ \frac{181\,995}{\sqrt{|\Delta|}} &\leq \alpha_6^*(|\Delta|) \leq \frac{231\,109}{\sqrt{|\Delta|}}, \\ \frac{251\,164}{\sqrt{|\Delta|}} &\leq \alpha_8^*(|\Delta|) \leq \frac{264\,410}{\sqrt{|\Delta|}}, \\ \frac{99\,324}{\sqrt{|\Delta|}} &\leq \alpha_{10}^*(|\Delta|) \leq \frac{100\,541}{\sqrt{|\Delta|}}, \\ \frac{15\,720}{\sqrt{|\Delta|}} &\leq \alpha_{12}^*(|\Delta|) \leq \frac{15\,768}{\sqrt{|\Delta|}}. \end{aligned}$$

**Corollary 1.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field. Then*

$$E_4^{(\mathbb{K})^2} = E_8^{(\mathbb{K})}$$

*holds if and only if  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$ .*

*Proof.* If  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$ , then the identity follows from [4], Theorem 6. Suppose  $|\Delta| \geq 4$ . The Fourier coefficient of  $I$  in  $E_4^{(\mathbb{K})^2} - E_8^{(\mathbb{K})}$  is

$$2\alpha_4^*(|\Delta|) + 2\alpha_4^*(0)^2 - \alpha_8^*(|\Delta|) \geq \frac{17\,584}{\sqrt{|\Delta|}} + 115\,200 - \frac{264\,410}{\sqrt{|\Delta|}} > 0,$$

according to (7), whenever  $|\Delta| \geq 5$ . For  $\Delta = -4$  a direct computation shows that this Fourier coefficient is nonzero.  $\square$

Clearly the restriction of  $E_4^{(\mathbb{K})^2} - E_8^{(\mathbb{K})}$  to  $\mathbb{S}_2$  vanishes because  $\dim \mathcal{M}_8(\Gamma_2) = 1$ . If  $\mathbb{K} = \mathbb{Q}(\sqrt{-1})$  then [4], Theorem 10, yields

$$(8) \quad E_4^{(\mathbb{K})^2} - E_8^{(\mathbb{K})} = c\phi_4^2 \text{ for } c = 230\,400/61.$$

**Corollary 2.** *Let  $\mathbb{K} = \mathbb{Q}(\sqrt{-1})$ . Then the graded ring of symmetric Hermitian modular forms with respect to the maximal discrete extension of  $\Gamma_2^{(\mathbb{K})}$  is the polynomial ring in*

$$E_k^{(\mathbb{K})}, \quad k = 4, 6, 8, 10, 12.$$

*Proof.* [4], Corollary 9 and (8).  $\square$

Let  $e_{k,m}^{(\mathbb{K})} : \mathbb{H}_1 \times \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$  denote the  $m$ -th Fourier-Jacobi coefficient of  $E_k^{(\mathbb{K})}$  belonging to  $J_{k,m}(\mathcal{O}_{\mathbb{K}})$ , the space of Hermitian Jacobi forms of weight  $k$  and index  $m$  (cf. [11]). Note that the first Fourier-Jacobi coefficient of  $E_4^{(\mathbb{K})^2} - E_8^{(\mathbb{K})}$  vanishes on the submanifold

$\{(\tau, z, z); \tau \in \mathbb{H}_1, z \in \mathbb{C}\}$ . Let  $\mathcal{M}_k(\Gamma_1)$  stand for the space of elliptic modular forms of weight  $k$ . Then the result of Eichler-Zagier [6], Theorem 3.5, yields

**Corollary 3.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field,  $\mathbb{K} \neq \mathbb{Q}(\sqrt{-3})$ . If  $k \geq 4$  is even, the mapping*

$$\begin{aligned} \mathcal{M}_{k-4}(\Gamma_1) \times \mathcal{M}_{k-6}(\Gamma_1) \times \mathcal{M}_{k-8}(\Gamma_1) &\rightarrow J_{k,1}(\mathcal{O}_{\mathbb{K}}), \\ (f, g, h) &\mapsto f e_{4,1}^{(\mathbb{K})} + g e_{6,1}^{(\mathbb{K})} + h e_{8,1}^{(\mathbb{K})} \end{aligned}$$

is an injective homomorphism of the vector spaces, which turns out to be an isomorphism for  $\mathbb{K} = \mathbb{Q}(\sqrt{-1})$ .

*Proof.* Note that the dimensions on both sides are equal to  $\lfloor \frac{k}{4} \rfloor$  due to [4], Theorem 3, whenever  $\mathbb{K} = \mathbb{Q}(\sqrt{-1})$ .  $\square$

We give a precise description of  $e_{k,1}^{(\mathbb{K})}$ .

**Lemma 1.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field and let  $k \geq 4$  be even. Then the first Fourier-Jacobi coefficient of  $E_k^{(\mathbb{K})}$  is given by*

$$\begin{aligned} e_{k,1}^{(\mathbb{K})}(\tau, z, w) &= \frac{1}{2} \sum_{\substack{c,d \in \mathbb{Z} \\ \gcd(c,d)=1}} \sum_{\lambda \in \mathcal{O}_{\mathbb{K}}} (c\tau + d)^{-k} \exp(2\pi i [(a\tau + b)\lambda\bar{\lambda} - czw + (z\lambda + w\bar{\lambda})] / (c\tau + d)). \end{aligned}$$

*Proof.* Proceed in the same way as Eichler/Zagier [6] in § 6. One knows that  $E_k^{(\mathbb{K})}$  is an eigenform under all Hecke operators  $\mathcal{T}_2(p)$  for all inert primes  $p$  from [16]. On the other hand the Jacobi-Eisenstein series is an eigenform under

$$\begin{aligned} \mathcal{T}_J(p) &= \Gamma_J^{(\mathbb{K})} \text{diag}(1, p, p^2, p) \Gamma_J^{(\mathbb{K})}, \\ \Gamma_J^{(\mathbb{K})} &= \left\{ \begin{pmatrix} * & * & * & * \\ 0 & 0 & 0 & 1 \end{pmatrix} \in \Gamma_2^{(\mathbb{K})} \right\}, \quad p \in \mathbb{P} \text{ inert.} \end{aligned}$$

As in both cases the constant Fourier coefficient is 1, the claim follows.  $\square$

**Remark 1.** a) If  $E_k$  denotes the normalized Eisenstein series of weight  $k$  for some group  $\Gamma$ , then the identity  $E_4^2 = E_8$  is well-known for elliptic modular forms and Siegel modular forms of degree 2 (cf. [19], [7]). But it also holds for modular forms of degree 2 with respect to the Hurwitz order (cf. [15], p. 89) as well as the integral Cayley numbers (cf. [5]), i.e. for  $O(2,6)$  and  $O(2,10)$ . Hence this identity is a hint at the influence of the arithmetic of the attached number field on the modular forms.

b) Note that  $E_k^{(\mathbb{K})}$  is a modular form with respect to the maximal discrete extension of  $\Gamma_2^{(\mathbb{K})}$  (cf. [17], [22]).

c) It follows from (4) that the Fourier coefficients  $\varepsilon_{t,\ell}^{(\Delta)}$  are also multiplicative in  $\Delta$ , i.e.

$$\varepsilon_{t,\ell}^{(\Delta)} = \varepsilon_{t,\ell}^{(\Delta_1)} \cdot \dots \cdot \varepsilon_{t,\ell}^{(\Delta_r)}.$$

- d) Due to Corollary 3 the dimension of the Maaß space in  $\mathcal{M}_k(\Gamma_2^{(\mathbb{K})})$  is  $\geq \lfloor \frac{k}{4} \rfloor$  for  $\mathbb{K} \neq \mathbb{Q}(\sqrt{-3})$  and equal to  $\lfloor \frac{k+2}{6} \rfloor$  for  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$  (cf. [4]), if  $k \in \mathbb{N}$  is even.  
e) If  $k > 4$  is even we can improve the estimate from [16] slightly for all  $T \in \Lambda_2$ ,  $T > 0$ :

$$\begin{aligned} & \frac{(2\pi)^{2k-1}}{(k-2)!(k-1)!} \cdot \frac{2 - \zeta(k-2)}{\zeta(k-1)\zeta(k)} \cdot \frac{1}{\sqrt{|\Delta|}} (\det T)^{k-2} \leq \alpha_k(T) \\ & \leq \frac{(2\pi)^{2k-1}}{(k-2)!(k-1)!} \cdot \frac{\zeta(k-3)\zeta(k-2)}{(2 - \zeta(k-1))\zeta(k)} \cdot \frac{1}{\sqrt{|\Delta|}} (\det T)^{k-2}. \end{aligned}$$

### 3 Algebraic independence

It is well-known that there are exactly 5 algebraically independent Hermitian modular forms. In this section we explicitly determine algebraically independent Eisenstein series.

We define the Siegel Eisenstein series  $S_k$  of degree 2 for even  $k \geq 4$

$$S_k(Z) = \sum_{\begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \backslash \Gamma_2} \det(CZ + D)^{-k}, \quad Z \in \mathbb{S}_2,$$

and denote its Fourier coefficients by  $\gamma_k(R)$ . Clearly  $E_k^{(\mathbb{K})}|_{\mathbb{S}_2} = S_k$  holds for  $k = 4, 6, 8$ . The following Fourier coefficients of  $S_k$  were computed by Igusa [12] and are given by

$f$	$\gamma_f \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$	$\gamma_f \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$	$\gamma_f \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1 \end{pmatrix}$
$S_4$	240	30 240	13 440
$S_6$	-504	166 320	44 352
$S_4 S_6$	-264	-45 360	57 792
$X_{12}$	65 520	402 585 120	39 957 120

$$X_{12} := 441S_4^3 + 250S_6^2.$$

**Lemma 2.** *Let  $\mathbb{K}$  be an imaginary quadratic number field. Then*

$$F_{10}^{(\mathbb{K})} := E_{10}^{(\mathbb{K})} - E_4^{(\mathbb{K})} E_6^{(\mathbb{K})}, \quad F_{12}^{(\mathbb{K})} := E_{12}^{(\mathbb{K})} - \frac{441}{691} E_4^{(\mathbb{K})^3} - \frac{250}{691} E_6^{(\mathbb{K})^2}$$

are Hermitian cusp forms of weight 10 resp. 12, whose restrictions to  $\mathbb{S}_2$  do not vanish identically.

*Proof.* If  $F = F_{10}^{(\mathbb{K})}, F_{12}^{(\mathbb{K})}$ , then (1) - (3) show that  $\alpha_F(T) = 0$  for all  $T \in \Lambda_2$ ,  $\det T = 0$ .

Hence  $F$  is a cusp form. The Fourier coefficients  $\beta_F(R)$  of  $F|_{\mathbb{S}_2}$  are given by

$$\beta_F(R) = \sum_{\substack{T \in \Lambda_2, T \geq 0 \\ T + \bar{T} = 2R}} \alpha_f(T).$$

Note that  $E_k^{(\mathbb{K})}|_{\mathbb{S}_2} = S_k$  for  $k = 4, 6, 8$ . If  $k = 10$ , then Theorem 1 and the above table yield  $\beta_F(I) > 0$ .

If  $k = 12$ , then for  $\Delta \neq -4$

$$(9) \quad \begin{aligned} \beta_F(I) &= \alpha_{12}^*(\Delta) + 2 \sum_{1 \leq j < \sqrt{|\Delta|}} \alpha_{12}^*(|\Delta| - j^2) - \frac{402\,585\,120}{691} \\ &\leq 15\,768 \left( \frac{1}{\sqrt{|\Delta|}} + 2 \right) - \frac{402\,585\,120}{691} < 0 \end{aligned}$$

by means of Theorem 1. If  $\Delta = -4$  then

$$\beta_F(I) = -\frac{20\,026\,621\,440\,000}{34\,910\,011} < 0. \quad \square$$

A simple consequence is

**Theorem 2.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field.*

a) *The graded ring of Siegel modular forms of even weight is generated by*

$$E_k^{(\mathbb{K})}|_{\mathbb{S}_2}, \quad k = 4, 6, 10, 12.$$

b) *If  $\mathbb{K} \neq \mathbb{Q}(\sqrt{-3})$  the Eisenstein series*

$$E_k^{(\mathbb{K})}, \quad k = 4, 6, 8, 10, 12$$

*are algebraically independent.*

*Proof.* a) Use Lemma 2.

b) Apply a) as well as Corollary 1. □

If  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$ , we already know the graded ring of Hermitian modular forms (cf. [4], Theorem 6).

**Corollary 4.** *If  $\mathbb{K} = \mathbb{Q}(\sqrt{-3})$  the graded ring of symmetric Hermitian modular forms of even weight with respect to  $\Gamma_2^{(\mathbb{K})}$  is the polynomial ring in*

$$E_k^{(\mathbb{K})}, \quad k = 4, 6, 10, 12, 18.$$

*Proof.* Use [4], Theorem 6, and show that

$$E_{18}^{(\mathbb{K})}, E_{12}^{(\mathbb{K})} \cdot E_6^{(\mathbb{K})}, E_{10}^{(\mathbb{K})} \cdot E_4^{(\mathbb{K})^2}, E_6^{(\mathbb{K})^3}, E_6^{(\mathbb{K})} \cdot E_4^{(\mathbb{K})^3}$$

are linearly independent by calculating a few Fourier coefficients using (1) - (4).  $\square$

**Remark 2.** a) It follows from the results of [3] that there is a non-trivial cusp form  $f_4^{(\mathbb{K})}$  of weight 4 for all discriminants except  $\Delta_{\mathbb{K}} = -3, -4, -7, -8, -11, -15, -20, -23$ . As its restriction to the Siegel half-space vanishes identically, one may replace  $E_8^{(\mathbb{K})}$  by  $f_4^{(\mathbb{K})}$  in these cases in Theorem 2 b).

b) Using Theorem 2 resp. Corollary 4 resp. part a) we can construct a non-trivial skew-symmetric Hermitian modular form of weight 44 resp. 54 resp. 40 by an application of a suitable differential operator (cf. [1]).

## 4 A Siegel cusp form

We consider

$$(10) \quad \begin{aligned} G_k^{(\mathbb{K})}(Z) &:= E_k^{(\mathbb{K})}(Z) - S_k(Z), \quad Z \in \mathbb{S}_2, \\ &= \sum_{\substack{\begin{pmatrix} A & B \\ C & D \end{pmatrix} : \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \setminus \Gamma_2^{(\mathbb{K})} \\ C^{\sharp} D \notin \mathbb{R}^{2 \times 2}}} \det(CZ + D)^{-k}, \end{aligned}$$

where  $\begin{pmatrix} c_1 & c_2 \\ c_3 & c_4 \end{pmatrix}^{\sharp} = \begin{pmatrix} c_4 & -c_2 \\ -c_3 & c_1 \end{pmatrix}$ . For  $\mathbb{K} = \mathbb{Q}(\sqrt{-1})$  this modular form was introduced by Nagaoka and Nakamura [20].

**Theorem 3.** *Let  $\mathbb{K}$  be an imaginary-quadratic number field. If  $k \geq 10$  is even, then  $G_k^{(\mathbb{K})}$  is a Siegel cusp form of degree 2 and weight  $k$  in the Maaß space.*

a) One has

$$(11) \quad \lim_{|\Delta_{\mathbb{K}}| \rightarrow \infty} G_k^{(\mathbb{K})}(Z) = 0 \text{ for all } Z \in \mathbb{S}_2.$$

b)  $G_k^{(\mathbb{K})} \not\equiv 0$  holds whenever  $k \geq \frac{10}{3}|\Delta_{\mathbb{K}}| + 1$ .

*Proof.*  $G_k^{(\mathbb{K})}$  is a cusp form, as all its Fourier-coefficients  $\beta_k(R)$  with  $\det R = 0$  vanish due to (1) - (4). It belongs to the Maaß space by virtue of [16] and [10].

a) Because  $\dim \mathcal{M}_k(\Gamma_2) \leq 1$  for  $k < 10$  (cf. [7]), we have  $G_k^{(\mathbb{K})} \equiv 0$  for  $k = 4, 6, 8$ . Let  $k \geq 10$  and

$$S_1 = \begin{pmatrix} 0 & 0 & P \\ 0 & -S & 0 \\ P & 0 & 0 \end{pmatrix}, \quad P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad S = \begin{pmatrix} 2 & 0 \\ 0 & |\Delta|/2 \end{pmatrix}, \quad \text{resp.} \quad \begin{pmatrix} 2 & 1 \\ 1 & (|\Delta| + 1)/2 \end{pmatrix},$$

if  $\Delta$  is even resp. odd. Then the explicit isomorphism in [17] yields

$$(12) \quad G_k^{(\mathbb{K})}(Z) = \sum_{\substack{h \in \mathbb{Z}^6, h_4 \geq 1 \\ h^{tr} S_1 h = 0, \gcd(S_1 h) = 1}} \left( -h_1 \det Z + \text{trace} \left( \begin{pmatrix} h_2 & g \\ \bar{g} & h_5 \end{pmatrix} \cdot Z \right) + h_6 \right)^{-k},$$

where  $g = h_3 + h_4 \sqrt{\Delta}/2$  resp.  $g = h_3 + h_4(1 + \sqrt{\Delta})/2$ . By virtue of [15], V.2.5, it suffices to show that the series in (12) over the absolute values at  $Z = iI$  tends to 0, as  $|\Delta| \rightarrow \infty$ . Hence we consider

$$\begin{aligned} I_\Delta &:= \sum_h |h_1 + h_6 + i(h_2 + h_5)|^{-k} \\ &= \sum_h \left( h_1^2 + h_6^2 + h_2^2 + h_5^2 + (h_3 h_4) S \begin{pmatrix} h_3 \\ h_4 \end{pmatrix} \right)^{-k/2} \end{aligned}$$

in view of  $h^{tr} S_1 h = 0$ . As  $h_4 \geq 1$  we get

$$I_\Delta \leq \sum_h \left( \frac{|\Delta| - 3}{2} + \frac{1}{2} h^{tr} h \right)^{-k/2} \leq (|\Delta| - 3)^{-k/4} \cdot \sum_h (h^{tr} h)^{-k/4}.$$

If  $k \geq 14$  we can use the Epstein zeta function for  $I^{(6)}$  in order to obtain  $\lim_{|\Delta| \rightarrow \infty} I_\Delta = 0$ . For  $k = 10$  and  $k = 12$  apply

$$a + b \geq \sqrt[4]{a} \cdot \sqrt[4]{b^3} \text{ for } a, b > 0$$

and proceed in the same way.

b) Let  $\Delta$  be fixed. Then the Fourier coefficient  $\beta_k(I)$  of  $G_k^{(\mathbb{K})}$  is given by

$$\beta_k(I) = \alpha_k^*(\Delta) + 2 \sum_{1 \leq j \leq \sqrt{\Delta}} \alpha_k^*(\Delta - j^2) - \gamma_k(I).$$

Due to Maaß [18]

$$0 < \gamma_k(I) = \frac{-4k B_{k-1, \chi_{-4}}}{B_k B_{2k-2}}$$

holds. Using Corollary 1 this leads to

$$\begin{aligned} \beta_k(I) &\geq r_{k, \Delta} \left( (2 - \zeta(k-2)) \left( |\Delta|^{k-2} + 2 \sum_{1 \leq j \leq \sqrt{|\Delta|}} (|\Delta| - j^2)^{k-2} \right) - \frac{B_{k-1, \chi_{-4}} B_{k-1, \chi}}{(k-1) B_{2k-2}} \right) \\ &\geq r_{k, \Delta} |\Delta|^{k-3/2} \left( \frac{2 - \zeta(k-2)}{\sqrt{|\Delta|}} - \frac{2^{2k-2} (k-1)!^2 \zeta(k-1)^2}{(k-1) \zeta(2k-2) (2k-2)!} \right) \end{aligned}$$

for  $\Delta \neq -4$ , if we use (5) and (6). Then Stirling's formula leads to

$$\begin{aligned} \beta_k(I) &\geq r_{k,\Delta} |\Delta|^{k-3/2} \left( \frac{2 - \zeta(k-2)}{\sqrt{|\Delta|}} - \frac{e^{1/6(k-1)} \zeta(k-1)^2}{\zeta(2k-2)} \sqrt{\frac{\pi}{k-1}} \right) \\ &\geq r_{k,\Delta} |\Delta|^{k-3/2} \left( \frac{2 - \zeta(8)}{\sqrt{|\Delta|}} - e^{1/54} \zeta(9)^2 \sqrt{\frac{\pi}{k-1}} \right), \end{aligned}$$

as  $k \geq 10$ . The expression in the bracket is positive because

$$k-1 \geq \frac{10}{3} |\Delta| > \pi \left( \frac{e^{1/54} \zeta(9)^2}{2 - \zeta(8)} \right)^2 |\Delta|.$$

If  $\Delta = -4$  we compute  $\beta_k(R)$ ,  $R = \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1 \end{pmatrix}$ , and proceed in the same way (cf. [20]).  $\square$

Use the description of  $\gamma_k(R)$  by means of Cohen's function in [6], p. 80. A comparison of the Fourier coefficients and the Hecke bound for the Fourier coefficients of cusp forms yield the following asymptotic.

**Corollary 5.** *If  $k \geq 4$  is even and  $N \in \mathbb{N}$ ,  $N \equiv 0, 3 \pmod{4}$  one has*

$$H(k-1, N) \sim \sum_{\substack{|j| \leq \sqrt{|\Delta|N} \\ j \equiv \Delta N \pmod{2}}} \alpha_{k,\Delta}^*((|\Delta|N - j^2)/4)$$

as  $N \rightarrow \infty$  for any imaginary-quadratic number field  $\mathbb{K}$ .

**Remark 3.** a) We know that  $G_k^{(\mathbb{K})} \equiv 0$  for  $k = 4, 6, 8$ . Hence we get equality for  $k = 4, 6, 8$  in Corollary 5. We conjecture that  $G_k^{(\mathbb{K})} \not\equiv 0$  for any even  $k \geq 10$  and any imaginary-quadratic number field  $\mathbb{K}$ . This has been verified for  $|\Delta_{\mathbb{K}}| \leq 500$  by the authors. The Fourier coefficients are not always positive as in the proof of Theorem 3 (cf. [9]).

b) The paramodular group of level  $t$  can be embedded into  $\Gamma_2^{(\mathbb{K})}$ , whenever  $t$  is the norm of an element in  $\mathcal{O}_{\mathbb{K}}$  (cf. [13]). Hence one can construct paramodular cusp forms in the Maaß space in the same way.

## 5 The Maaß Spezialschar

At first we characterize the vanishing of  $G_k^{(\mathbb{K})}$ . Recall (e.g. [21], Theorem 3.14) that for even  $k \in \mathbb{N}$  the *Shimura lifts* are maps

$$\begin{aligned} Sh_{k,t-1/2} : \mathcal{S}_{k-1/2}(\Gamma_0(4)) &\rightarrow \mathcal{S}_{2k-2}(SL_2(\mathbb{Z})) \\ f(\tau) = \sum_{n=1}^{\infty} a(n)e^{2\pi in\tau} &\mapsto \sum_{n=1}^{\infty} b_t(n)e^{2\pi in\tau}, \end{aligned}$$

for squarefree  $t \in \mathbb{N}$ , where the coefficients  $b_t(n)$  are given by

$$\sum_{n=1}^{\infty} b_t(n)n^{-s} = \sum_{n=1}^{\infty} \left(\frac{t}{n}\right) n^{k-s-3/2} \cdot \sum_{n=1}^{\infty} a(tn^2)n^{-s}.$$

Let  $\mathcal{S}_{k-N_2}^+(\Gamma_0(4))$  be Kohnen's plus space, i.e.

$$a(n) = 0 \text{ for } n \equiv 1, 2 \pmod{4}.$$

**Lemma 3.** *Let  $k \geq 4$  be even and  $\mathbb{K} = \mathbb{Q}(\sqrt{-t})$ ,  $t \in \mathbb{N}$  squarefree. Then the following are equivalent:*

- (i) *The restriction of the Hermitian Eisenstein series  $E_k^{(\mathbb{K})}|_{\mathbb{S}_2}$  is equal to the Siegel Eisenstein series  $S_k$ .*
- (ii) *The  $t$ -Shimura lift  $Sh_{t,k-1/2} : \mathcal{S}_{k-1/2}^+(\Gamma_0(4)) \rightarrow \mathcal{S}_{2k-2}(SL_2(\mathbb{Z}))$  is identically zero.*

*Proof.* As  $E_k^{(\mathbb{K})}|_{\mathbb{S}_2}$  is the Maaß lift of  $e_k^{(\mathbb{K})}(\tau, z, z)$ , condition (i) holds if and only if  $e_k^{(\mathbb{K})}(\tau, z, z)$  is equal to the classical Jacobi-Eisenstein series in [6]. Due to Lemma 1 one has

$$e_k^{(\mathbb{K})}(\tau, z, z) = \sum_{\lambda \in \mathcal{O}_{\mathbb{K}}} \sum_{M: \Gamma_{\infty} \backslash \Gamma_1} e^{2\pi i(\tau\lambda\bar{\lambda} + z(\lambda + \bar{\lambda}))}|_{k,1} M,$$

if we use the definition of the slash operator from [6]. For each fixed  $\lambda$  the series

$$\sum_{M: \Gamma_{\infty} \backslash \Gamma_1} e^{2\pi i(\tau\lambda\bar{\lambda} + z(\lambda + \bar{\lambda}))}|_{k,1} M = P_{k,\lambda\bar{\lambda},\lambda+\bar{\lambda}}(\tau, z)$$

is the Jacobi-Poincaré series (cf. [23]). Its Petersson inner product with a cusp form  $\phi$  is, up to a factor depending on  $k$  as well as  $(\lambda - \bar{\lambda})^{6-4k}$ , equal to the Fourier coefficient of the term  $e^{2\pi i(\tau\lambda\bar{\lambda} + z(\lambda + \bar{\lambda}))}$ . Thus (i) holds if and only if

$$\sum_{0 \neq \lambda \in \mathcal{O}_{\mathbb{K}}} (\lambda - \bar{\lambda})^{6-4k} c(\lambda\bar{\lambda}, \lambda + \bar{\lambda}) = 0$$

holds for every Jacobi cusp form

$$(13) \quad \phi(\tau, z) = \sum_{n,r} c(n, r) e^{2\pi i(n\tau + rz)} \in \mathcal{J}_{k,1}.$$

We want to rephrase this in terms of half-integral weight modular forms for  $\Gamma_0(4)$  as in [6], §5. Given (13) we attach the modular form

$$F(\tau) = \sum_{\substack{N \in \mathbb{N} \\ N=4n-r^2}} c(n, r) e^{2\pi i N \tau} \in \mathcal{M}_{k-1/2}(\Gamma_0(4)),$$

satisfying Kohnen's plus condition. This bijection respects the Petersson inner products up to a trivial factor. The half-integral weight modular form attached to  $P_{k, \lambda \bar{\lambda}, \lambda + \bar{\lambda}}$  is therefore the projection to the Kohnen plus space of the Poincaré series of weight  $k - 1/2$  and index  $-(\lambda - \bar{\lambda})^2$ . As  $\lambda$  runs through  $\mathcal{O}_{\mathbb{K}}$  these values run through  $|\Delta|n^2$ ,  $n \in \mathbb{N}_0$ . Hence (i) holds if and only if

$$\sum_{n=1}^{\infty} c(|\Delta|n^2) n^{3-2k} = 0$$

for every cusp form  $F(\tau) = \sum_{N \equiv 0,3 \pmod{4}} c(N) e^{2\pi i N \tau} \in S_{k-1/2}(\Gamma_0(4))$ . If such an  $F$  is a Hecke eigenform, then its Shimura lift  $Sh_{t, k-1/2}(F)$  is either a Hecke eigenform with the same eigenvalues or identically 0. In the first case the Euler product of its  $L$ -function implies that

$$\sum_{n=1}^{\infty} b_t(n) n^{3-2k} \neq 0$$

and thus

$$\sum_{n=1}^{\infty} a(tn^2) n^{3-2k} \neq 0.$$

Therefore (i) holds if and only if all the Hecke eigenforms in  $\mathcal{S}_{k-1/2}^+(\Gamma_0(4))$  map to 0 under  $Sh_{t, k-1/2}$ .  $\square$

This leads to our final result

**Corollary 6.** *Let  $k \geq 10$  be even. Then the modular form*

$$G_k^{(\mathbb{K})} = E_k^{(\mathbb{K})} \Big|_{\mathbb{S}_2} - S_k$$

*generate the subspace of cusp forms in the Maaß Spezialschar as a module over the Hecke algebra, as  $\mathbb{K}$  varies over all imaginary-quadratic number fields.*

*Proof.* Let  $\mathcal{A}_{k-1/2}(\Gamma_0(4)) \subseteq \mathcal{S}_{k-1/2}^+(\Gamma_0(4))$  be the subspace generated by the preimages of  $E_k^{\mathbb{Q}(\sqrt{t})} \Big|_{\mathbb{S}_2} - S_k$  under the Maaß lift as  $t$  runs through all squarefree numbers in  $\mathbb{N}$ . In the proof of Lemma 3 it was shown that a Kohnen plus Hecke eigenform  $F \in \mathcal{S}_{k-1/2}^+(\Gamma_0(4))$

is orthogonal to  $\mathcal{A}_{k-1/2}(\Gamma_0(4))$  if and only if its  $t$ -Shimura lifts  $Sh_{t,k-1/2}(F)$  are 0 for all squarefree  $t \in \mathbb{N}$ . This cannot happen by a theorem of Kohnen [14], which guarantees that some linear combination of Shimura lifts yields a Hecke-equivariant isomorphism

$$\mathcal{S}_{k-1/2}^+(\Gamma_0(4)) \xrightarrow{\sim} \mathcal{S}_{2k-2}(\Gamma_1).$$

It follows that  $\mathcal{A}_{k-1/2}(\Gamma_0(4))$  generates  $\mathcal{S}_{k-1/2}^+(\Gamma_0(4))$  as a module over the Hecke algebra. Since Maaß lifts respect Hecke operators, we obtain the claim.  $\square$

**Remark 4.** a) Lemma 3 is trivial for  $k = 4, 6, 8$  because

$$\mathcal{S}_k(\Gamma_2) = \mathcal{S}_{2k-2}(\Gamma_1) = \{0\}.$$

b) It is an open question whether the modular forms  $G_k^{(\mathbb{K})}$  span the space of cusp forms in the Maaß space of even weight  $k \geq 10$ , when  $\mathbb{K}$  runs over all imaginary-quadratic number fields.
