The amplituhedron crossing and winding numbers

Xavier Blot*, Jian-Rong Li†

Abstract
In [AHTT18], Arkani-Hamed, Thomas and Trnka formulated two conjectural descriptions of the tree amplituhedron $A_{n,k,m}$ depending on the parity of $m$. When $m$ is even, the description involves the winding number and when $m$ is odd the description involves the crossing number. In this paper, we prove that if a point is in the open tree amplituhedron then it satisfies the crossing or winding description.

1 Introduction

1.1 Overview

The (tree) amplituhedron $\mathcal{A}_{n,k,m}$ is a subspace of the Grassmannian $\mathrm{Gr}_{k,k+m}$ introduced by Arkani-Hamed and Trnka in [AHT14] in order to compute scattering amplitude of a certain quantum field theory. From the mathematical perspective, it is a generalization of the totally nonnegative Grassmannian $\mathrm{Gr}_{k,n}^{\geq 0}$ with many interesting properties. For example, in [GKL21] it is proved that a certain amplituhedron is homeomorphic to a ball, in [EZLT21, GL20, Lam16] results about cell decompositions of the tree amplituhedron are given. See also [KW19] and [PSBW21] for a description of the tree amplituhedron when $m = 1$ and $m = 2$.

The original definition of the amplituhedron in [AHT14] is purely geometrical: the amplituhedron is the image in $\mathrm{Gr}_{k,k+m}$ of the nonnegative Grassmannian $\mathrm{Gr}_{k,n}^{>0}$ by a map. This definition has the advantage to be simple but it is very hard to check whether or not a point of $\mathrm{Gr}_{k,k+m}$ belongs to the amplituhedron. In [AHTT18], Arkani-Hamed, Trnka and Thomas gave two conjectural definitions of the amplituhedron, one for $m$ even and the other one for $m$ odd, which answer this question. Depending on the parity of $m$, they associate an integer to each point of $\mathrm{Gr}_{k,k+m}$ called the winding number or the crossing number. To compute these numbers it suffices to calculate the so-called twistor coordinates, themselves obtained by computing determinants of matrices. Then, they conjectured that a point of $\mathrm{Gr}_{k,k+m}$ is inside $\mathcal{A}_{n,k,m}$ if and only if it satisfies some boundary conditions and the crossing or winding number has a specific value depending on $k$ and $m$. The boundary conditions are also checked by computing twistor coordinates, thus, according to their definition, it suffices to compute determinants to know if a point of $\mathrm{Gr}_{k,k+m}$ is inside the amplituhedron or not.

In this paper, we prove one implication of these conjectures: if a point is in the amplituhedron, then its crossing or winding number is given by this specific value and it satisfy the boundary conditions. When $m = 2$, we also prove the reverse implication. Along the way, we obtain some equations involving twistor coordinates, the C- and Z-equations, valid for any $k, m, n$, which can be of independent interest. We also give an alternative proof of a third definition of the amplituhedron involving sign flips of twistor coordinates.
1.2 The amplituhedron

Definition 1.1. Let \((n, k, m)\) be a triplet of nonnegative integers such that \(k + m \leq n\). Let \(Z\) be an element of \(\text{Mat}_{n,k+m}^{>0}\). This matrix induces a map

\[
\tilde{Z} : \text{Gr}_{k,n}^{>0} \to \text{Gr}_{k,k+m}
\]

or equivalently, if \(C\) is a \(k \times n\) matrix representing \(\text{Span}(c_1, \ldots, c_k)\) in \(\text{Gr}_{k,n}^{>0}\) then \(\tilde{Z}(C)\) is represented by \(CZ\). The \((tree)\ amplituhedron\ \mathcal{A}_{n,k,m}\) is the image of \(\text{Gr}_{k,n}^{>0}\) by the map \(\tilde{Z}\).

We also denote by \(\mathcal{A}_{n,k,m}^0\) the image of \(\text{Gr}_{k,n}^{>0}\) by \(\tilde{Z}\).

Definition 1.2 (Twistor coordinates). Let \((n, k, m)\) be a triplet of nonnegative integers such that \(k + m \leq n\). Let \(Z \in \text{Mat}_{n,k+m}^{>0}\) and denote by \(Z_1, \ldots, Z_n \in \mathbb{R}^{k+m}\) its \(n\) rows. Let \(Y \in \text{Gr}_{k,k+m}\) and denote by \(Y_1, \ldots, Y_k \in \mathbb{R}^{k+m}\) the \(k\) rows of a matrix representing \(Y\). Let \((i_1, \ldots, i_m)\) be a list of elements of \([n]\). The twistor coordinate \(\langle Y, Z_{i_1}, \ldots, Z_{i_m} \rangle\) of \(Y\), denoted by

\[
\langle Y, Z_{i_1}, \ldots, Z_{i_m} \rangle,
\]

is the determinant of \((Y_1, \ldots, Y_k, Z_{i_1}, \ldots, Z_{i_m})\).

Remark 1.3. The twistor coordinates of \(Y\) are defined up to a global nonzero factor, corresponding to the choice of a representative of the \(k\)-plan \(Y\), but this factor will not matter.

Notation 1.4. When \(Z\) is understood, we denote the twistor coordinate \(\langle Y, Z_{i_1}, \ldots, Z_{i_m} \rangle\) by \(\langle Y, i_1, \ldots, i_m \rangle\). We will also denote the determinant of \((Z_{i_1}, \ldots, Z_{i_{k+m}})\) by \(\langle i_1, \ldots, i_{k+m} \rangle\), for any list \((i_1, \ldots, i_{k+m})\) of elements of \([n]\).

1.3 Coarse boundary of the amplituhedron

Let \(Y \in \mathcal{A}_{n,k,m}\). It follows from the Cauchy-Binet formula and the positivity of the minors that certain twistor coordinates are positive: when \(m\) is even we have

\[
\begin{cases}
\langle Y, I \rangle \geq 0 & \text{for } I = (i_1, i_1 + 1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}} + 1) \in \binom{[n]}{m}, \\
(-1)^{k+1} \langle Y, I, n, 1 \rangle \geq 0 & \text{for } I = (i_1, i_1 + 1, \ldots, i_{\frac{m}{2}-1}, i_{\frac{m}{2}-1} + 1) \in \binom{[2,n-1]}{m-2},
\end{cases}
\]

whereas when \(m\) is odd we have

\[
\begin{cases}
(-1)^k \langle Y, 1, I \rangle \geq 0 & \text{for } I = (i_1, i_1 + 1, \ldots, i_{\frac{m+1}{2}-1}, i_{\frac{m+1}{2}-1} + 1) \in \binom{[2,n]}{m-1}, \\
\langle Y, I, n \rangle \geq 0 & \text{for } I = (i_1, i_1 + 1, \ldots, i_{\frac{m+1}{2}-1}, i_{\frac{m+1}{2}-1} + 1) \in \binom{n-1}{m-1}.
\end{cases}
\]

See Lemma 2.1 for a proof. Furthermore, these inequalities are strict if \(Y \in \mathcal{A}_{n,k,m}^0\). In most of the cases, these inequalities are not refined enough to determine whether or not a point of \(\text{Gr}_{k,k+m}\) is in the amplituhedron.
Definition 1.5. We call Eq. (1) and Eq. (2) the coarse boundary conditions of the amplituhedron.

Let $\mathcal{L}$ be the locus of points in $\text{Gr}_{k,k+m}$ where the inequalities of Eq. (1) or Eq. (2), depending on the parity of $m$, are equalities. We define

$$A_{n,k,m}^{\text{wcb}} := A_{n,k,m} \setminus \mathcal{L}$$

and

$$\text{Gr}_{k,k+m}^{\text{wcb}} := \text{Gr}_{k,k+m} \setminus \mathcal{L},$$

the notation referring to “without coarse boundary”. In particular, we have

$$A_{n,k,m}^o \subset A_{n,k,m}^{\text{wcb}} \subset A_{n,k,m}.$$  

1.4 Projection and simplices

Fix a $k$-plan $Y$ in $\mathbb{R}^{k+m}$ and the $n$ vectors $Z_1, \ldots, Z_n$ in $\mathbb{R}^{k+m}$. Denote by $V_Y$ the quotient space $\mathbb{R}^{k+m}/Y$ and by

$$\pi_Y : \mathbb{R}^{k+m} \to V_Y \cong \mathbb{R}^m$$

the quotient map.

Notation 1.6. When $Z$ and $Y$ are understood, we denote $Z_i := \pi_Y(Z_i)$ for $1 \leq i \leq n$.

Remark 1.7. Let $Y \in \text{Gr}_{k,k+m}$ and let $(f_1, \ldots, f_m)$ be a basis of a complement of $Y$ in $\mathbb{R}^{k+m}$, then $B = (\pi_Y(f_1), \ldots, \pi_Y(f_m))$ is a basis of $V_Y$. Then, the list

$$\left( \text{sign} \left( \det_B(Z_{i_1}, \ldots, Z_{i_m}) \right), 1 \leq i_1, \ldots, i_m \leq n \right),$$

where $\det_B$ is the determinant in the basis $B$, is equal to the list

$$\left( \text{sign} \left( \langle Y, Z_{i_1}, \ldots, Z_{i_m} \rangle \right), 1 \leq i_1, \ldots, i_m \leq n \right),$$

up to a global sign. Thus, we will interpret signs of twistor coordinates as signs of determinants of $Z_i$ in $V_Y$.

The definitions of the winding number and the crossing number use simplices in $V_Y$ that we introduce now.

Definition 1.8. For any subset $I$ of $[n]$, we denote $S(I)$ the simplex in $\mathbb{R}^{k+m}$ given by convex hull of the points $Z_i$, for $i \in I$ in $\mathbb{R}^{k+m}$. We denote by $S(I)$ the image of the simplex $S(I)$ by $\pi_Y$. We call $S(I)$ a simplex even if its vertices are not necessarily affinely independant. If the vertices $Z_i$, for $i \in I$, of $S(I)$ are affinely independent, we say that $S(I)$ is full dimensional.
1.5 The winding number

Let $m$ be an even positive integer. Fix $k, n$ such that $n \geq k + m$. Fix also $Z \in \text{Mat}_{n,k+m}^>$, and denote by $Z_1, \ldots, Z_n$ its $n$ rows.

We associate a number, the winding number, to any point $Y \in \text{Gr}_{k,k+m}^{\text{wcb}}$ in the following way. Let $P(Y,Z)$ be the following polyhedron in $V_Y$

$$P(Y,Z) := \bigcup_I S(I) \bigcup_J S(J,n,1) \subset V_Y,$$

where $I = (i_1, i_1 + 1, \ldots, i_m, i_m + 1)$ is a strictly ascending list of positive integers between 1 and $n$, and $J = (j_1, j_1 + 1, \ldots, j_{m-1}, j_{m-1} + 1)$ is a strictly ascending list of positive integers between 2 and $n-1$. Let $S^{k-1}$ be the $(k-1)$-sphere centered in the origin of $V_Y$ of radius 1.

We define the map $f : P \to S^{k-1}$

$$f : x \mapsto \frac{x}{\|x\|},$$

where $\|\cdot\|$ is a norm on $V_Y$. Note that since $Y \in \text{Gr}_{k,k+m}^{\text{wcb}}$, the origin of $V_Y$ does not belong to $P(Y,Z)$ and then $f$ is well defined.

**Definition 1.9 (Winding number).** The **winding number**

$$w_{k,n,m}(Y,Z)$$

is the degree of the map $f$ (i.e. the image of the homology class of $P(Y,Z)$ by the map $f_* : H_{k-1}(P(Y,Z)) \to H_{k-1}(S^{k-1}) \simeq \mathbb{Z}$)

It corresponds to the number of times that $P$ winds around the origin of $V_Y$.

**Remark 1.10.** For a generic $Y \in \text{Gr}_{k,k+m}^{\text{wcb}}$, the ray issued from almost all vectors of $V_Y$ intersects the simplices of $P(Y,Z)$ only in their $m$-dimensional interior. Pick $Y$ generic enough and such a vector, say $Z_*$, in $V_Y$. Then the degree of $f$ is given by the number of simplices intersecting the ray issued from $Z_*$ weighted by a sign corresponding to the orientation of the simplex. We recover in these cases the definition of the winding number of [AHTT18].

**Theorem 1.** The winding is independent of $Y \in A_{n,k,m}^\text{wcb}$, of $Z \in \text{Mat}_{n,k+m}^>$, and it equals

$$w_{n,k,m}(Y,Z) = \left(\left\lfloor \frac{k+m-1}{m} \right\rfloor \right).$$

(3)

**Remark 1.11.** It is apparent from Eq. (3) that the winding number is also independent of $n$ when $Y \in A_{n,k,m}^\text{wcb}$ and $Z \in \text{Mat}_{n,k+m}^>$. 
A point in $A_{n,k,m}$ also satisfies the coarse boundary conditions Eq. (1). In [AHTT18], the authors also conjectured the inverse implication: a point with the correct winding number and satisfying the coarse boundary condition is in the amplituhedron. This implication is still open.

**Open problem 1.12.** Does a point $Y \in \text{Gr}_{k,k+m}$ with the correct winding number and satisfying the coarse boundary conditions $\text{Eq. (1)}$ belongs to $A_{n,k,m}$?

When $m = 2$, the following proposition gives a positive answer to this problem. It allows to give an alternative definition of the $m = 2$ amplituhedron in terms of the winding number, see Corollary 1.14.

**Proposition 1.13.** Fix $m = 2$. Let $Y \in \text{Gr}_{k,k+2}$ and $Z \in \text{Mat}_{n,k+2}^{>0}$.

1. We have $w_{n,k,2}(Y,Z) \leq \left\lfloor \frac{k+1}{2} \right\rfloor$.

2. If $w_{n,k,2}(Y,Z) = \left\lfloor \frac{k+1}{2} \right\rfloor$ and satisfies the coarse boundary conditions, see Eq. (1), then $Y \in A_{n,k,2}$.

**Corollary 1.14.** Let $Y \in \text{Gr}_{k,k+2}$ and $Z \in \text{Mat}_{n,k+2}^{>0}$. The point $Y$ is in $A_{n,k,2}$ if and only if $w_{n,k,2}(Y,Z) = \left\lfloor \frac{k+1}{2} \right\rfloor$ and $Y$ satisfies the coarse boundary conditions, see Eq. (1).

### 1.6 The crossing number

Let $m$ be an odd positive integer, we write $m = 2r - 1$ with $r$ a positive integer. Fix $k, n$ such that $n \geq k + m$. Fix also $Z \in \text{Mat}_{n,k+2}^{>0}$, and denote by $Z_1, \ldots, Z_n$ its $n$ rows.

We associate a number, the crossing number, to any point $Y \in \text{Gr}_{k,k+m}$ in the following way. Start from a $k$-plan $Y$ in $\mathbb{R}^{k+m}$ and the $n$ vectors $Z_1, \ldots, Z_n$ in $\mathbb{R}^{k+m}$. Let $(i_1, i_1 + 1, i_2, \ldots, i_r + 1)$ be a strictly ascending list of positive integers between 1 and $n$. We decompose the simplex $S(i_1, \ldots, i_r + 1)$ into cells:

- the 0-cells are the vertices $Z_{i_1}, Z_{i_1+1}, \ldots, Z_{i_r}$ and $Z_{i_r+1}$ of $S(i_1, \ldots, i_r + 1)$,
- let $1 \leq a \leq 2r - 1$. For any choice of $(a + 1)$ affinely independant vertices of $S(i_1, \ldots, i_r + 1)$, say $Z_{j_1}, \ldots, Z_{j_{a+1}}$ where \( \{j_1, \ldots, j_{a+1}\} \subset \{i_1, i_1 + 1, i_2 + 1, \ldots, i_r + 1\} \), we define the $a$-cell $\mathcal{C}(j_1, \ldots, j_{a+1})$ to be the relative interior of the convex hull of $\pi_Y(Z_{j_1}), \ldots, \pi_Y(Z_{j_{a+1}})$.

Denote by $\text{Cells}$ the set of all the cells of the simplices $S(i_1, \ldots, i_r + 1)$ for any list $(i_1, i_1 + 1, i_2, \ldots, i_r + 1)$ of a strictly ascending integers between 1 and $n$.

**Definition 1.15.** The crossing number

$c_{n,k,m}(Y,Z)$

is the number of cells in $\text{Cells}$ containing the origin $\pi_Y(Y)$ of $V_Y$. 

6
Remark 1.16. Suppose the origin \( \pi_Y(Y) \) of \( V_Y \) is contained only in \( m \) dimensional cells (i.e. in the interior of the simplices). Then the crossing number counts the number of simplices of type \( S(i_1, i_1 + 1, i_2, \ldots, i_r + 1) \) containing the origin \( V_Y \). In this particular case, it follows from Remark 1.7 that the origin belongs to the simplex \( S(I) \) if and only if the sequence 

\[
(\text{sign} \langle Y, I \backslash \{i\} \rangle)_{i \in I}
\]

is alternating. Thus, Definition 1.15 of the crossing number agrees with the definition of [AHTT18]. Otherwise, the two definitions differ and Theorem 2 only holds using Definition 1.15.

Theorem 2. The crossing number is independent of \( Y \in A_{n,k,m}^0 \) and of \( Z \in \text{Mat}_{n,k+m}^{>0} \), and it equals

\[
c_{n,k,m}(Y, Z) = \begin{cases} 
\frac{2k+m-1}{m+1}\left(\frac{k+m-2}{m+1}\right)^{\frac{m+1}{2}} & \text{for } k \text{ odd}, \\
2\left(\frac{k+m-1}{m+1}\right)^{\frac{m+1}{2}} & \text{for } k \text{ even},
\end{cases}
\]

(4)

Remark 1.17. It is apparent from Eq. (4) that the crossing number is independent of \( n \) when \( Y \in A_{n,k,m}^0 \) and \( Z \in \text{Mat}_{n,k+m}^{>0} \).

It is also apparent from Eq. (4) that the crossing number is independent of \( n \).

Remark 1.18. From the explicit formulas of the winding number Eq. (3) and of the crossing number Eq. (4), we obtain the following relation between the crossing and the winding numbers

\[
c_{n,k,m}(Y, Z) = \begin{cases} 
2w_{n,k,m+1}(Y, Z) - w_{n,k,m-1}(Y, Z) & \text{for } k \text{ odd}, \\
w_{n,k,m+1}(Y, Z) & \text{for } k \text{ even},
\end{cases}
\]

for \((Y, Z) \in A_{n,k,m}^0 \times \text{Mat}_{n,k+m}^{>0}\). This relation can be directly deduced by geometrical reasons. See [AHTT18, Section 4] for an idea of the argument.

A point in \( A_{n,k,m}^0 \) also satisfies the coarse boundary conditions Eq. (2). In [AHTT18], the authors also conjectured the inverse implication: a point with the correct crossing number and satisfying the coarse boundary condition is in the amplituhedron. This implication is still open.

Open problem 1.19. Does a point \( Y \in \text{Gr}_{k,k+m} \) satisfying Eq. (2) and Eq. (4) belongs to \( A_{n,k,m}^0 \)?

1.7 Organization of the paper

In Section 2, we prove Theorem 1. We first prove that the winding number \( w_{k,n,m}(Y, Z) \) is constant when \((Y, Z) \in A_{n,k,m}^{\text{wcb}} \times \text{Mat}_{n,k+m}^{>0}\). Then we prove that the winding number is also independent of \( n \). Finally, we obtain the explicit expression of the winding number for \( n = k + m \). In last subsection, we prove the we prove the \( m = 2 \) maximality statements of the winding for Proposition 1.13.
In section 3, we prove Theorem 2. The proof follows the same path. We first prove that the crossing number $c_{n,k,m}(Y,Z)$ is constant when $(Y,Z) \in A^0_{n,k,m} \times \text{Mat}_{n,k+m}^>$. In this case, this part is more subtle. It requires to first prove two sets of equations on twistor coordinates that we call $C$-equations and $Z$-equations. We emphasize that these equations are valid for every $n, k$ and $m$. We deduce from these equations that we can avoid unpleasant behavior of the simplices and cells involved in the count of the crossing number, and then prove the constancy of the crossing number in $A^o_{n,k,m} \times \text{Mat}_{n,k+m}^>$. Then we prove the independence of the crossing number in $n$, and finally we obtain the explicit expression of the crossing for $n = k + m$.

The two sections are independent.

2 The winding number

In this section $m$ will denote an even integer.

2.1 Preliminaries

Throughout the text, we use the Cauchy-Binet formula to develop twistor coordinates. A formulation of this development is given by Lemma 3.3 of [PSBW21]. Let us recall the statement.

**Lemma 2.1** ([PSBW21]). Let $Z \in \text{Mat}_{n,k+m}^>$. Write $Y \in \text{Gr}_{k,k+m}$ as $Y = CZ$ with $C \in \text{Gr}_{k,n}$.

We have

$$\langle CZ, i_1, \ldots, i_m \rangle = \sum_{J = (j_1 \prec \ldots \prec j_k) \in \binom{[n]}{k}} p_J(C) \langle j_1, \ldots, j_k, i_1, \ldots, i_m \rangle,$$

where we used Notation 1.4.

For completeness, we include a proof.

**Proof.** We have

$$\langle CZ, i_1, \ldots, i_m \rangle = \det \left( \begin{array}{c} C \\ I_{i_1, \ldots, i_m} \end{array} \right) Z,$$

where $I_{i_1, \ldots, i_m}$ is the $m \times n$ matrix such that the $l$th row has a 1 in position $i_l$ and zeros elsewhere. We then use the Cauchy-Binet formula to obtain the result. \hfill \Box

In particular, (strict) inequalities of the coarse boundary conditions, Eq. (1) and Eq. (2), follow from the positivity of $Z \in \text{Mat}_{n,k+m}^>$ and the (strict) positivity of $C \in \text{Gr}_{k,n}^>$.
2.2 Constancy of the winding number in $A_{n,k,m}^{\text{web}} \times \text{Mat}_{n,k,m}^{> 0}$

Proposition 2.2. Fix $n, k$ and $m$ even such that $n \geq k + m$. The winding number $w_{n,k,m} : A_{n,k,m}^{\text{web}} \times \text{Mat}_{n,k,m}^{> 0} \to \mathbb{Z}$ is constant.

Remark 2.3. We can prove in a similar way that the winding number is constant is each path connected component of $\text{Gr}_{k,k,m}^{> 0} \times \text{Mat}_{n,k,m}^{> 0}$.

Proof. Let $Z, Z' \in \text{Mat}_{n,k,m}^{> 0}$ and $Y, Y' \in A_{n,k,m}^{\text{web}}$. Let $C, C' \in \text{Gr}_{k,n}^{> 0}$ such that $Y = CZ$ and $Y' = C'Z'$.

Since $\text{Gr}_{k,n}^{> 0}$ and $\text{Mat}_{n,k,m}^{> 0}$ are path connected (see [Pos06] for the positive Grassmannian) and $\text{Gr}_{k,n}^{> 0} = \text{Gr}_{k,n}$, there exists a path

$$(\tilde{C}, \tilde{Z}) : [0, 1] \to \text{Gr}_{k,n}^{> 0} \times \text{Mat}_{n,k,m}^{> 0}$$

such that $$(\tilde{C} \times \tilde{Z})(0) = (Z, C), \quad (\tilde{C} \times \tilde{Z})(1) = (Z', C')$$ and such that $\tilde{C}(t) \in \text{Gr}_{k,n}^{> 0}$ for $t \in [0, 1]$. The winding number

$$w_{n,k,m}(\tilde{Y}(t), \tilde{Z}(t)),$$

where $\tilde{Y}(t) := \tilde{C} \tilde{Z}$, is independent of $t$. Indeed, the winding number may change only as a result of an intersection between the origin $\pi_{\tilde{Y}(t)}(\tilde{Y}(t))$ of $V_{\tilde{Y}}$ and the polytope $P(\tilde{Y}(t), \tilde{Z}(t))$.

However, for every $t \in [0, 1]$ we have $\tilde{Y}(t) \in A_{n,k,m}^{\text{web}}$, hence $\tilde{Y}(t)$ satisfies the strict inequality of the coarse boundary condition Eq. (1), thus the the origin $\pi_{\tilde{Y}(t)}(\tilde{Y}(t))$ of $V_{\tilde{Y}(t)}$ does not hit the polytope $P(\tilde{Y}(t), \tilde{Z}(t))$.

2.3 Independence of the winding number in $n$

We show in this section that for a specific choice of points in $A_{n,k,m}^{\text{web}}$ and $\text{Mat}_{n,k,m}^{> 0}$, the winding number does not depend on $n$. Since, we proved that the winding number $w_{n,k,m}(Y, Z)$ is independent of $Y \in A_{n,k,m}^{\text{web}}$ and $Z \in \text{Mat}_{n,k,m}^{> 0}$, we deduce that the winding number is also independent of $n$.

Proposition 2.4. There exist $(Z', C') \in \text{Mat}_{n+1,k,m}^{> 0} \times \text{Gr}_{k,n+1}^{> 0}$ and $(Z, C) \in \text{Mat}_{n,k,m}^{> 0} \times \text{Gr}_{k,n}^{> 0}$ such that

$$w_{n,k,m}(CZ, Z) = w_{n+1,k,m}(C'Z', Z').$$

Proof. In Step 1, we introduce $(Z', C')$ and $(Z, C)$. Then, in Step 2 we view the polytopes $P(CZ, Z)$ and $P(C'Z', Z')$ associated to these points as singular chains. We prove that
the difference \( Q = P\left(C' \mathcal{Z}', \mathcal{Z}'\right) - P(C \mathcal{Z}, \mathcal{Z}) \) is given by a sum of boundaries of singular \( m \)-simplices. Finally in Step 3, we use this formula to prove that the winding of \( Q \) is zero. This implies that the winding of \( P\left(C' \mathcal{Z}', \mathcal{Z}'\right) \) is equal to the winding of \( P(C \mathcal{Z}, \mathcal{Z}) \).

**Step 1.** Choose \( \mathcal{Z}' = (Z_1, \ldots, Z_{n+1}) \in \text{Mat}^>_{n+1,k+m} \) then \( Z = (Z_1, \ldots, Z_n) \in \text{Mat}^>_{n,k+m} \). Let \( C \in \text{Gr}^>_{k,n} \) and let \( Y = C \mathcal{Z} \in A^>_{n,k,m} \). We define the matrix \( C' \) by adding a \((n+1)\)th column of zeros to \( C \). It follows from Lemma 2.1 together with the positivity of \( \mathcal{Z}' \) and \( C \) that \( Y^C = \mathcal{Z}'^C \) does not belong to the coarse boundary of the amplituhedron:

\[
\left\langle C' \mathcal{Z}', I \right\rangle \neq 0 \tag{6}
\]

for any subset \( I = \left(i_1, i_1 + 1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}} + 1 \right) \) or \( I = \left(i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n + 1, 1 \right) \) in \( \left(\begin{array}{c} n + 1 \\ m \end{array}\right) \) or \( \). Hence the winding number \( w_{n+1,k,m}(Y, (Z_1, \ldots, Z_{n+1})) \) is well defined.

**Step 2.** Let \( P(Y, \mathcal{Z}) \) and \( P(Y, \mathcal{Z}') \) be the polytopes associated to \( \mathcal{Z} \) and \( \mathcal{Z}' \) in \( V_Y \). We consider \( P(Y, \mathcal{Z}) \) as a singular chain given by the sum of the singular simplices

\[
\Delta^{m-1} \rightarrow S\left(i_1, i_1 + 1 \ldots, i_{\frac{m}{2}} + 1\right) \quad \text{and} \quad \Delta^{m-1} \rightarrow S\left(i_1, i_1 + 1 \ldots, i_{\frac{m}{2} - 1} + 1, n, 1\right)
\]

where \( \Delta^{m-1} \) is the standard \((m-1)\)-simplex \((e_1, \ldots, e_m)\) in \( \mathbb{R}^m \) and the first (resp. second) map is the linear map sending the basis \((e_1, \ldots, e_m)\) of \( \mathbb{R}^m \) to \((Z_{i_1}, Z_{i_1+1}, \ldots, Z_{i_{\frac{m}{2}}+1})\) (resp. \((Z_{i_1}, Z_{i_1+1}, \ldots, Z_n, Z_1))\). Similarly, we consider \( P(Y, \mathcal{Z}') \) as a singular chain. We have

\[
\partial P(Y, \mathcal{Z}) = \partial P(Y, \mathcal{Z}') = 0.
\]

Write \( Q := P\left(Y, \mathcal{Z}'\right) - P(Y, \mathcal{Z}) \). It is then a closed chain and does not intersect the origin, so its winding number is well defined. Moreover, the winding number associated to \( P\left(Y, \mathcal{Z}'\right) \) is equal to the winding number of \( P(Y, \mathcal{Z}) \) plus the winding number of \( Q \). We now prove that the winding number of \( Q \) is zero, hence proving Eq. (5).

We prove that

\[
Q = \sum \partial \sigma_{i_1, i_1+1, \ldots, i_{\frac{m}{2}}+1, i_{\frac{m}{2}-1}, i_{\frac{m}{2}-1}+1, n, n+1, 1, 1}, \tag{7}
\]

where the summation is over strictly ascending lists of integers \( \left(i_1, i_1 + 1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}} + 1 \right) \) between \( 2 \) and \( n-2 \). We used the notation \( \sigma(I) \) to denote the singular simplex \( \Delta^{|I|-1} \rightarrow S(I) \).

The singular simplices \( \sigma_{i_1, i_1+1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}}+1, n, n+1} \) and \( \sigma_{i_1, i_1+1, \ldots, i_{\frac{m}{2}-1}, i_{\frac{m}{2}-1}+1, n, n+1, 1, 1} \) in \( \partial \sigma_{i_1, i_1+1, \ldots, i_{\frac{m}{2}-1}, i_{\frac{m}{2}-1}+1, n, n+1, 1, 1} \) come with a positive sign. These simplices belong to the set of
simplices of $P \left(Y, Z'\right)$ not in $P \left(Y, Z\right)$. On the other hand, the simplices $\sigma_{i_1, i_1 + 1, \ldots, i_{m-1}, i_{m-1} + 1, n, 1}$ come with a minus sign and are exactly the simplices of $P \left(Y, Z\right)$ not in $P \left(Y, Z'\right)$.

The rest of the simplices are of the form $\sigma_{i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{m-1}, i_{m-1} + 1, 1, n, 1}$ for some $1 \leq j \leq \frac{m-1}{2}$ and $\epsilon \in \{0, 1\}$. The set of indices $\{i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{m-1}, i_{m-1} + 1\}$ is uniquely described as disjoint union of intervals $I_1 \sqcup I_2 \sqcup \ldots \sqcup I_r$, where each $I_k$ is a sequence of consecutive integers in $\{2, \ldots, n - 1\}$, and the least element of $I_{k+1}$ is greater by at least 2 from the largest element of $I_k$. More precisely there is a unique interval of odd size, we denote it by $I_{k_0}$. There are now two possibilities; either $\{2, n - 1\} \not\subseteq I_{k_0}$, or exactly one element of $\{2, n - 1\}$ belongs to $I_{k_0}$ (if both of them were in $I_{k_0}$ then $m$ must have been 0).

If $2, n - 1 \not\in I_{k_0}$, then each simplex $\sigma_{i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{m-1}, i_{m-1} + 1, 1, n, 1}$ appear twice in $Q$ with opposite sign. Indeed, let $I^+_{k_0}$ be the extension of $I_{k_0}$ by the least integer greater than all the elements of $I_{k_0}$, and let $I^-_{k_0}$ be the extension of $I_{k_0}$ by the largest integer smaller than all the elements of $I_{k_0}$. Write

$$I^\pm = I^\mp_{k_0} \sqcup \bigcup_{i \not\in k_0} I_i.$$  

Then $\sigma_{i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{m-1}, i_{m-1} + 1, 1, n, 1}$ appears exactly in $\partial P \left(Y, Z\right)$ and $\partial P \left(Y, Z'\right)$ with opposite sign.

If $2$ or $n - 1$ belongs to $I_{k_0}$, say 2, then $I_{k_0} = I_1$ and $\epsilon = 1$. Then the simplex $\sigma_{i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{m-1}, i_{m-1} + 1, 1, n, 1}$ is the simplex of $P \left(Y, Z'\right)$ with the set of indices $\{j_1, j_1 + 1, \ldots, j_{m-1}, j_{m-1} + 1, 1, n, 1\}$ such that $j_1 = 1$ and $I_1 = \{j_1 + 1, j_2, j_2 + 1, \ldots, j_t + 1\}$, $I_r = \{j_{r-1} + 1, j_{r-1} + 1, \ldots, j_{m-1}, j_{m-1} + 1\}$.

Moreover, the sign of this simplex agrees with its sign in $P \left(Y, Z'\right)$. In the same way, if $n - 1 \in I_{k_0}$, we obtain simplices of type $\sigma_{i_1, i_1 + 1, \ldots, i_{m-1}, i_{m-1} + 1, n, 1}$, where $i_{m-1} + 1$. This completes the list of simplices of $P \left(Y, Z'\right)$ not in $P \left(Y, Z\right)$.

Putting everything together, we see that all simplices appearing in Eq. (7) cancel in pairs, except exactly those simplices which are simplices $P \left(Y, Z'\right)$ but not of $P \left(Y, Z\right)$, or of $P \left(Y, Z\right)$ but not of $P \left(Y, Z'\right)$, and in both of these cases they appear with the correct sign. Thus, Eq. (7) holds.

**Step 3.** We now show that the winding number of $Q$ is zero. Let $(i_1, i_1 + 1, \ldots, i_{m-1}, i_{m-1} + 1)$ be a strictly ascending lists of integers between 2 and $n - 2$. The boundary
\[ \partial \sigma_{i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1} \text{ is a cycle and this cycle does not touch the origin of } V_\gamma. \] Indeed, up to modifying \( C \) in \( \text{Gr}_{k,n}^0 \) we have

\[ \left\langle C^* \mathcal{Z}', i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1 \right\rangle \neq 0, \]

for \( j \in \left[ \frac{m}{2} \right] \) and \( \epsilon \in \{0, 1\} \). This is possible since by Lemma 2.1 these twistor coordinates only involve the minors of \( C \), and the vanishing of these twistor coordinates is a codimension 1 locus. Moreover, the rest of the twistor coordinates \( \left\langle Y, i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, \hat{n}, n + 1, 1 \right\rangle, \)

\[ \left\langle Y, i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1 \right\rangle \]

and \( \left\langle Y, i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1 \right\rangle \)

do not vanish since \( Y = C \mathcal{Z} = C^* \mathcal{Z}' \) does not belong to the coarse boundary of the amplituhedron. Hence the winding number of \( \partial \sigma_{i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1} \) is well defined. Moreover, it follows from Eq. (7) that the winding number of \( Q \) is the sum of the winding numbers of such cycles. We show that the winding number of \( \partial \sigma_{i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1} \) is zero.

Suppose the winding number of \( \partial \sigma_{i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1} \) is non zero, then the simplex \( \sigma_{i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1} \) is of dimension \( m \) and contains the origin of \( V_\gamma \). As mentioned in Remark 1.10, this implies that the sign of its twistor coordinates is alternating:

\[
\text{sgn} \left( \hat{i}_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1 \right) \\
= -\text{sgn} \left( i_1, \hat{i}_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, n + 1, 1 \right) \\
= \ldots \\
= \text{sgn} \left( i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, \hat{n}, n + 1, 1 \right) \\
= -\text{sgn} \left( i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, \hat{n} + 1, 1 \right).
\]

However the last equality cannot hold. Indeed, since \( Y = C \mathcal{Z} \) and \( C \) is positive, the strict coarse boundary conditions give \( \text{sgn} \left( Y, i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, n, \hat{n} + 1, 1 \right) = (-1)^{k+1} \).

On the other hand, since \( Y = C^* \mathcal{Z}' \) it follows from Eq. (6) and the coarse boundary conditions that \( \text{sgn} \left( i_1, i_1 + 1, \ldots, i_{\frac{m}{2} - 1}, i_{\frac{m}{2} - 1} + 1, \hat{n}, n + 1, 1 \right) = (-1)^{k+1} \). This concludes the proof. \( \Box \)

### 2.4 The winding number for \( n = k + m \)

Suppose \( m \) even. We show that there exists \( \mathcal{Z} \in \text{Mat}_{n,n}^{\geq 0} \) and \( C \in \text{Gr}_{k,k+m}^0 \) such that the winding number is

\[
w_{n=k+m,k,m}(C \mathcal{Z}, \mathcal{Z}) = \left( \left\lceil \frac{k+m-1}{2} \right\rceil \right). \quad (8)
\]

Since we showed that the winding number is independent of \( \mathcal{Z} \in \text{Mat}_{n,n}^{\geq 0} \), of \( Y \in \mathcal{A}_{n,k,m}^{\text{web}} \) and of \( n \), this proves Theorem 1.
Step 1. Since $C \in \text{Gr}_{k,k+m}^2$, it follows from the strict coarse boundary conditions that each simplex involved in $P(Y, Z)$ of full dimension equal to $m - 1$. Then we choose $0 < \mu < 1$ and the ray issued from the vector

$$Z_\ast = Z_n + \mu Z_{n-1} + \cdots + \mu^{m-1} Z_{n-m+1}$$

avoids the $(m - 2)$-skeleton of $P(Y, Z)$ (that is $P(Y, Z)$ minus its maximal cells) in $V_Y$. This is always possible since $(Z_n, \ldots, Z_{n-m+1})$ is a basis of $V_Y$ and the skeleton is of codimension 2. Thus, the ray issued from $Z_\ast$ can only intersect a simplex of $P(Y, Z)$ in its interior. Hence, the winding number is given by counting the number of simplices intersected in their interior by the ray $Z_\ast$, counted with a weight $\pm 1$ depending on the orientation of the simplex. More precisely, let $I$ be either a list $(i_1, i_1 + 1, \ldots, i_{\frac{n}{2}}, i_{\frac{n}{2}} + 1)$ of strictly ascending integers between 1 and $n$, or a list $(i_1, i_1 + 1, \ldots, i_{\frac{n}{2}-1}, i_{\frac{n}{2}-1} + 1, n, 1)$ of integers such that $i_1, i_1 + 1, \ldots, i_{\frac{n}{2}-1}, i_{\frac{n}{2}-1} + 1$ are strictly ascending between 1 and $n - 1$. We define the elementary winding number $w_{I,\ast}$ to be $+1$ if for every $j \in \{1, m\}$ we have

$$\text{sign} \langle Z_\ast, I \setminus \{j\text{th element}\} \rangle = (-1)^j \text{sign} \langle I \rangle$$

and 0 otherwise. Thus, the elementary winding number $w_{I,\ast}$ is 1 precisely if the ray $Z_\ast$ hits the simplex $S(I)$ in its interior. Then, we have

$$w_{k,m} = \sum_I \text{sign} \langle I \rangle \times w_{I,\ast},$$

where the summation is over the lists described above. Since $C \in \text{Gr}_{k,k+m}^2$, we have

$$\text{sign} \langle i_1, i_1 + 1, \ldots, i_{\frac{n}{2}}, i_{\frac{n}{2}} + 1 \rangle = +1$$

and the negative weights in the summation only appear for $I = (i_1, i_1 + 1, \ldots, i_{\frac{n}{2}-1}, i_{\frac{n}{2}-1} + 1, n, 1)$ and $k$ even.

Step 2. In order to compute the winding number, it suffices to compute signs of certain twistor coordinates. Since $n = k + m$, this boils down to compute the sign of determinants of square $k + m$ matrices.

If $I = (i_1, i_1 + 1, \ldots, i_{\frac{n}{2}}, i_{\frac{n}{2}} + 1)$, we have

$$\text{sign} \langle Z_\ast, I \setminus \{i_j + \epsilon\} \rangle = (-1)^{k+i_j+(1-\epsilon)},$$

$j \in \{1, m\}$ and $\epsilon \in \{0, 1\}$. Indeed, we have

$$\langle Z_\ast, i_1, i_1 + 1, \ldots, i_j + \epsilon, \ldots, i_{\frac{n}{2}}, i_{\frac{n}{2}} + 1 \rangle = \det\left(\begin{array}{c} C \\ V_n \\ I_{i_1, i_1+1, \ldots, i_j+\epsilon, \ldots, i_{\frac{n}{2}}, i_{\frac{n}{2}}+1} \end{array}\right) \det(Z),$$

13
where \( V_* = (0, \ldots, 0, \mu^{n-m+1}, \ldots, \mu^0) \) and \( I_{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1} \) is the \((m-1) \times (k+m)\) matrix whose \( l \)th row has a 1 at the \( l \)th index of the list \( i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1 \) and zeros elsewhere. We develop the rows of \( I \), the only row possibly contributing to the determinant is the one with a +1 in the position \( j + (1 - \varepsilon) \), since the signs coming from the development of the other rows compensate two by two. We obtain

\[
\det \begin{pmatrix} C & V_* \\ I_{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1} \end{pmatrix} = (-1)^{k+j+(1-\varepsilon)} \det \begin{pmatrix} C_{[n]\backslash \{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1\}} & (V_*)_{[n]\backslash \{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1\}} \\ \end{pmatrix}.
\]

Finally, the sign of the determinant on the RHS is determined by the sign of its smallest order in \( \mu \) since \( 0 < \mu \ll 1 \). There are two cases depending on \( M = \max([n] \backslash I) \). If \( i_j + 1 < M \) this determinant is given by

\[
\mu^{n-M} \left( (-1)^{k+1+1+M} \det \begin{pmatrix} C_{[n]\backslash \{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1\}\cup \{M\}} \end{pmatrix} + o(\mu^{n-M}) \right),
\]

where we used \( M \equiv n \equiv k \mod 2 \) to simplify the sign. If \( i_j > M \), then the determinant is given by

\[
\mu^{n-(i_j+\varepsilon)} (-1)^{k+1+i_j+\varepsilon} \det \begin{pmatrix} C_{[n]\backslash \{i_1, i_1+1, \ldots, j_1+\varepsilon, \ldots, j_m+1\}\cup \{M\}} \end{pmatrix} + o(\mu^{n-(i_j+\varepsilon)}),
\]

where we used that in this case \( i_j \equiv n-1 \equiv k-1 \mod 2 \). Thus, we deduce Eq. (10) from the positivity of \( C \) and \( Z \).

If \( I = \left(i_1, i_1+1, \ldots, i_{\frac{m}{2}}-1, i_{\frac{m}{2}}-1+1, n, 1\right) \), we obtain in a similar way

\[
\text{sign} \langle Z_* , I \backslash \{i_j+\varepsilon\} \rangle = (-1)^{i_j+(1-\varepsilon)},
\]

where \( j \in \{1, \frac{m}{2}-1\} \) and \( \varepsilon \in \{0, 1\} \). We also have

\[
\text{sign} \langle Z_* , I \backslash \{n\} \rangle = +1 \quad \text{and} \quad \text{sign} \langle Z_* , I \backslash \{1\} \rangle = (-1)^{k+1}.
\]

**Step 3.** We now count the number of simplices contributing to the winding number. There are two types of simplices: simplices of type (a) associated to lists \( \left(i_1, i_1+1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}}+1\right) \) of strictly ascending integers between 1 and \( n \), and simplices of type (b) associated to lists \( \left(i_1, i_1+1, \ldots, i_{\frac{m}{2}}-1, i_{\frac{m}{2}}-1+1, n, 1\right) \) of integers such that \( i_1, i_1+1, \ldots, i_{\frac{m}{2}}, i_{\frac{m}{2}}+1 \) are strictly ascending between 1 and \( n-1 \).

If \( k \) is odd, it follows from Eq. (12) that a simplex of type (b) cannot satisfy Eq. (9). However, it follows from Eq. (10) that simplex of type (a) contributes by +1 to the winding number if and only if

\[
i_1 \equiv i_2 \equiv \cdots \equiv i_{\frac{m}{2}} \equiv 0 \mod 2,
\]

(11)
where $1 \leq i_1 \leq \cdots \leq i_{m/2} \leq n - 1$. Thus, the winding number is equal to the number of such sequences $i_1, \ldots, i_{m/2}$, there are
\[
\binom{n-1}{m/2} = \binom{k+m-1}{m/2}
\]
possibilities. This ends the proof of Eq. (8) for $k$ odd.

If $k$ is even, a simplex of type (a) contributes by $+1$ to the winding number if and only if
\[
i_1 \equiv i_2 \equiv \cdots \equiv i_{m/2} \equiv 1 \mod 2,
\]
where $1 \leq i_1 \leq \cdots \leq i_{m/2} \leq n - 1$. There are \(\binom{n}{m/2}\) possibilities. Moreover, a simplex of type (b) contributes by $-1$ to the winding number if and only if
\[
i_1 \equiv i_2 \equiv \cdots \equiv i_{m/2-1} \equiv 0 \mod 2,
\]
where $1 \leq i_1 \leq \cdots \leq i_{m/2-1} \leq n - 2$. There are \(\binom{n-2}{m/2}\) possibilities. Thus, the winding number is equal to
\[
\binom{n}{m/2} - \binom{n-2}{m/2} = \binom{n-1}{m/2},
\]
that is Eq. (8) for $n = k + m$ and $k$ even.

This ends the proof of Theorem 1.

2.5 Maximality of the winding number for $m = 2$

In this subsection, we prove Proposition 1.13 that we recall now. Fix $Y \in \text{Gr}_{wcb}^{k,k+2}$ and $Z \in \text{Mat}_{n,k+2}^{>0}$. We prove in the first part that
\[
w_{n,k,2}(Y,Z) \leq \left\lfloor \frac{k+1}{2} \right\rfloor,
\]
and in the second part that if $w_{n,k,2}(Y,Z) = \left\lfloor \frac{k+1}{2} \right\rfloor$ and satisfies the coarse boundary conditions Eq. (1), then $Y \in A_{n,k,2}$.

**Proof of part 1.** Denote by $s$ the number of sign flips of $(\langle Y,1,i \rangle)_{i \in [n]}$. We show that
\[
\begin{cases}
2w_{n,k,2}(Y,Z) = s + 1 & \text{for } k \text{ odd}, \\
2w_{n,k,2}(Y,Z) = s & \text{for } k \text{ even}.
\end{cases}
\]
Then, it follows from Remark 3.8 that $s \leq k$. Thus we deduce that $w_{n,k,2}(Y,Z) \leq \left\lfloor \frac{k+1}{2} \right\rfloor$.

Since $Y \in \text{Gr}_{wcb}^{k,k+2}$ we have $\langle Y,1,n \rangle \neq 0$ and then the vector $Z_1$ is nonzero in $V_Y$. Choose $Z_*$ in $V_Y \setminus \{0\}$ in a small neighborhood of $Z_1$ such that the line $l$ generated by $Z_*$ avoids all
the points $Z_i$, for $1 \leq i \leq n$. This is always possible since $\cup_{1 \leq i \leq n} \text{span} (Z_i)$ is of codimension 1 in $V_Y$. Moreover, since $Y \in \text{Gr}^{\text{web}}_{k,k+2}$, the pair of vectors $(Z_i, Z_{i+1})$, for $1 \leq i \leq n-1$, or $(Z_1, Z_n)$ cannot be colinear. Hence, the line $l$ can only intersect a simplex $S(i,i+1)$ or $S(1,n)$ transversally and in its relative interior. In particular, the line intersects the simplex $S(i,i+1)$, for $1 \leq i \leq n-1$, if and only if $\text{sgn} \langle Y, Z_i, Z_i \rangle = -\text{sgn} \langle Y, Z_s, Z_{i+1} \rangle$ and the simplex $S(1,n)$ if and only if $\text{sgn} \langle Y, Z_s, Z_n \rangle = -\text{sgn} \langle Y, Z_s, Z_1 \rangle$. We say that the intersection is positive or negative if in addition to the intersection of the line with $S(i,i+1)$ (resp. $S(1,n)$) we have that $\text{sgn} \langle Y, i, i+1 \rangle$ is positive or negative (resp. $\text{sgn} \langle Y, 1, n \rangle$ is positive or negative). Then, by the definition of the winding number, we have

$$2w_{n,k,2}(Y, Z) = \left| \sum_{x \in \cap \mathcal{P}(Y,Z)} \epsilon(x) \right|,$$

where $\epsilon(x)$ is +1 if the intersection of $l$ and $P(Y,Z)$ at $x$ is positive and −1 if it is negative. In particular, we have

$$2w_{n,k,2}(Y, Z) \leq \sum_{x \in \cap \mathcal{P}(Y,Z)} 1.$$

Moreover, the number of intersections of $l$ with $P(Y,Z)$ is $s$ or $s+1$ depending on the parity of $k$. Indeed, by choosing $Z_s$ close enough to $Z_1$, we get that the number of sign flips $s$ of $(\langle Y, 1, i \rangle)_{i \in [n]}$ counts the number of intersections of $l$ with the simplices $S(i,i+1)$ for $1 \leq i \leq n-1$. If $k$ is even then $\text{sgn} \langle Y, Z_s, Z_2 \rangle = \text{sgn} \langle Y, Z_s, Z_n \rangle$. We can in addition choose $Z_s$ such that $Z_1$ and $Z_2$ belong to the same half plane of $\mathbb{R}^2 \setminus l$. Then $l$ does not intersect $S(1,2)$ and $S(1,n)$, so the number of intersections of $l$ with $P(Y,Z)$ is $s$. Similarly, if $k$ is odd, then with the same choice of $Z_s$ we see that $l$ intersects $S(1,n)$ and then the number of intersections of $l$ with $P(Y,Z)$ is $s+1$.

**Proof of part 2.** Now suppose that $Y \in \text{Gr}^{\text{web}}_{k,k+2}$ satisfies the coarse boundary conditions and $w_{n,k,2}(Y, Z) = \left\lfloor \frac{k+1}{2} \right\rfloor$. This implies by the first part of the proof that the number of sign flips $s$ of $(\langle Y, 1, i \rangle)_{i \in [n]}$ is maximal and equal to $k$. Hence, it follows from Theorem 5.1 of [PSBW21] that $Y \in \mathcal{A}_{n,k,2}$.

## 3 The crossing number

The goal of this section is to prove Theorem 2. The structure of the proof is similar to the case of the winding number: we first prove in Subsections 3.1, 3.2, 3.3 and 3.4 that the crossing number is independent of the point in $\mathcal{A}_{n,k,m}^{\circ} \times \text{Mat}_{n,k+m}^{\text{web}}$, then we prove in Subsection 3.5 that the crossing number is independent of $n$ and finally we obtain in Subsection 3.6 the explicit expression of the crossing number for $n = k + m$.

The first part of the proof, that is the constancy of the crossing number in $\mathcal{A}_{n,k,m}^{\circ} \times \text{Mat}_{n,k+m}^{\text{web}}$, is structured as follows. In Subsection 3.1 we derive two types of equations on
the twistor coordinates: the $C$-equations and the $Z$-equations. These equations involve the
Plücker coordinates of $C$ and $Z$, and are obtained from the Plücker relations. We emphasize
that they are valid for any $n, k, m$. From the $C$- and $Z$- equations, together with the positivity
of the minors of $C$ and $Z$, we deduce in Subsection 3.2 non trivial constraints on the twistor
coordinates. These constraints are used in Subsection 3.3 to exclude some configurations of
simplices relative to the origin in the projected space. These are precisely the configurations
where the crossing number can change. We then conclude in Subsection 3.4 that the crossing
number is constant in $A_{n,k,m}^\circ$.

3.1 The $C$-equations and the $Z$-equations

In this section, we derive two sets of equations involving the twistor coordinates: the $C$-
eqations and the $Z$-equations. These equations are obtain in the same way; they follow from
Plücker relations in $Gr_{k,n}$ and in $Gr_{k+m,n}$. In particular, the positivity of the minors of $C$ and
$Z$ is not necessary. Moreover, these equations are valid for any $m$, even or odd.

3.1.1 The $C$-equations

Let $[n]$ denote $\{1, \ldots, n\}$ and $\binom{[n]}{k}$ denote the set of $k$-elements subset of $[n]$. Let $I \in \binom{[n]}{k}$
and $V \in Gr_{k,n}$ represented by a $k \times n$ matrix $M$, then we denote by $p_{A,i}(C)$ the minor of $M$
relative to $I$. The minors $p_{I}(V)$ are the Plücker coordinates of $V$, they do not depend on the
choice of $M$ (up to simultaneous rescaling by a non zero constant).

**Proposition 3.1 (C-equations).** Let $(n, k, m)$ be a triplet of nonnegative integers such that
$k + m \leq n$. Let $Z$ be a $n \times (k + m)$ matrix with non vanishing determinant, let $C \in Gr_{k,n}$ and
$Y = Z(C)$. Let $A \in \binom{[n]}{k-1}$ and $B \in \binom{[n]}{m-1}$. The $C$-equations are

$$\sum_{i=1}^{n} p_{A,i}(C) \langle Y, B, i \rangle = 0, \quad (13)$$

where we used Notation 1.4 for the twistor coordinate $\langle Y, B, i \rangle$.

**Remark 3.2.** Both the vector of Plücker coordinates $(p_{A,i}(C))_{A,i}$ and the vector of twistor
coordinates $(\langle B, i \rangle)_{B,i}$ are defined up to a non zero multiplicative scalar, corresponding to the
choice of the matrix representing $C$ and $Y$. However these scalars do not affect Eq. (13).

We now prove the $C$-equations.

**Proof.** From Lemma 2.1 we get

$$\sum_{i=1}^{n} p_{A,i}(C) \langle Y, B, i \rangle = \sum_{i=1}^{n} \sum_{J=(j_1<\ldots<j_k)} p_{A,i}(C) p_{J}(C) \langle J, B, i \rangle. \quad (14)$$
Fix $L = \{l_1 < \cdots < l_{k+1}\} \in \binom{[n]}{k+1}$. We now extract the coefficient of the determinant $\langle l_1, \ldots, l_{k+1}, B \rangle$ in the RHS of Eq. (14). In this case, the index $i$ must be in $L$ and once it is fixed, we have $J = L \setminus \{i\}$. Taking care of the sign given by the antisymmetry of the determinant, we write the coefficient of $\langle l_1, \ldots, l_{k+1}, B \rangle$ in the RHS of Eq. (14) as
\[
(-1)^{k+m} \left( \sum_{\alpha=1}^{k+1} (-1)^\alpha p_{A,l_\alpha} (C) p_{l_1,\ldots,l_\alpha,\ldots,l_{k+1}} (C) \right).
\]

3.1.2 The $Z$-equations

**Proposition 3.3 (Z-equations)**. Let $(n, k, m)$ be a triplet of nonnegative integers such that $k + m \leq n$. Let $Z$ be a $n \times (k + m)$ matrix with non vanishing determinant and denote by $W = Z^T$ the $(k + m)$-plan in $\mathbb{R}^n$ generated by the columns of $Z$. Let $C \in \text{Gr}_{k,n}$ and $Y = \tilde{Z} (C)$. Let $A \in \binom{[n]}{k+m+1}$ and $B \in \binom{[n]}{m-1}$. The $Z$-equations are
\[
\sum_{i \in A} (-1)^{\#i} p_{A \setminus i} (W) \langle Y, B, i \rangle = 0,
\]
where $\#i$ is the position of $i$ in the list $A$.

**Proof.** Using Lemma 2.1 we get
\[
\sum_{i \in A} (-1)^{\#i} p_{A \setminus i} (W) \langle Y, B, i \rangle = \sum_{i \in A} \sum_{J \in \binom{[n]}{k}} (-1)^{\#i} p_J (C) p_{A \setminus i} (W) \langle J, B, i \rangle.
\]

Fix $J = (j_1 < \cdots < j_k) \in \binom{[n]}{k}$, the coefficient of $p_J (C)$ is
\[
\sum_{i \in A} (-1)^{\#i} p_{A \setminus i} (W) \langle J, B, i \rangle,
\]
and write this expression as
\[
\sum_{i \in A} (-1)^{\#i} p_{A \setminus i} (W) p_{I,B,i} (W).
\]
This last expression vanishes by Plücker relations in $\text{Gr}_{k+m,n}$. This proves the $Z$-equations.

3.2 Consequences of the $C$- and $Z$-equations on twistor coordinates

From now on, we suppose that $m = 2r - 1$ for $r \geq 1$. The purpose of this section is to deduce from the $C$- and $Z$-equations, together with positivity of the minors of $C$ and $Z$, the following constraints on twistor coordinates.
Proposition 3.4. Let $Y \in A_{n,k,m}$ and let $B = (b_1, b_1 + 1, \ldots, b_r - 1, b_r - 1 + 1)$ be a list of $2r - 2 = m - 1$ integers in $[n]$.

1. The list $\langle Y, B, i \rangle_{i \in [n] \setminus B}$ cannot contain three consecutive twistor coordinates $\langle Y, B, i^- \rangle, \langle Y, B, i_0 \rangle, \langle Y, B, i^+ \rangle$, such that
   
   $\langle Y, B, i_0 \rangle = 0$ and $\text{sign}(\langle Y, B, i^- \rangle) = \text{sign}(\langle Y, B, i^+ \rangle) \neq 0$,

   where the indices $(i^-, i_0, i^+)$ satisfy:
   
   $2 \leq i_0 \leq n - 1$ and
   
   $i^- = \max([1, \ldots, i_0 - 1] \cap B^c)$,
   
   $i^+ = \min([i_0 + 1, \ldots, n] \cap B^c)$,

   where $B^c$ is the complement of $B$ in $[n]$.

2. The list $\langle Y, B, i \rangle_{i \in [n] \setminus B}$ cannot contain two consecutive zeros.

We first establish, in Section 3.2.1, a sign flip property of the twistor coordinates. Then, in Section 3.2.2, we deduce from this property, together with the $Z$-equations, the proof of Proposition 3.4.

3.2.1 A sign flip property

The following lemma was stated in [AHTT18] and a sketch of a proof was given. It will be used in what follows. For completeness we provide another proof, which is based upon the $C^-$, $Z$-equations and the positivity of the minors.

Lemma 3.5. Let $Y \in A^0_{n,k,m}$ and let $B = (b_1, b_1 + 1, \ldots, b_r - 1, b_r - 1 + 1)$ be a list of $m - 1$ integers in $[n]$. Then, the number of times the list of numbers $\langle Y, B, i \rangle_{i \in [n]}$ changes sign (ignoring the zeros) is exactly $k$.

Remark 3.6. If $m = 2r$ is even, we can prove in the same way that if $B = (1, b_1, b_1 + 1, \ldots, b_r - 1, b_r - 1 + 1)$ or $\bar{B} = (b_1, b_1 + 1, \ldots, b_r - 1, b_r - 1 + 1, n)$, then the number of times the list $\langle Y, B, i \rangle_{i \in [n]}$ changes sign is exactly $k$.

We now prove the sign flip property.

Proof of Lemma 3.5. The proof splits in two steps.

Step 1. In this step we use the $C$-equations and the positivity of $C$, to deduce that the list $\langle Y, B, i \rangle_{i \in [n]}$, either changes sign at least $k$ times, or it is a list of zeros. The second possibility, that $\langle Y, B, i \rangle_{i \in [n]}$ is a list of zeros, is ruled out since the first and last element of the list do not satisfy the strict inequalities of the coarse boundary conditions (see Eq. (2)).
Suppose \((\langle Y, B, i \rangle)_{i \in [n]}\) changes sign \(q\) times with \(q < k\). Denote by \(s_1 < \cdots < s_q\) the positions of the sign flips. More precisely, let \(s_0\) be the smallest integer such that \(\langle Y, B, s_0 \rangle \neq 0\) and set
\[
s_i = \min \{ s \in [n] \mid s > s_{i-1} \text{ and } \text{sign}(s) = -\text{sign}(s_{i-1}) \}\.
\]
Define \(A = (a_1, \ldots, a_{k-1})\) by
\[
a_j = \max \{ j, s_j-(k-q)+1 \}, \quad \text{for} \quad 1 \leq j \leq k-1,
\]
with the convention that \(s_j = 0\) if \(j \leq 0\). More explicitly, let \(j_0\) be the smallest index such that \(a_{j_0} \neq j_0\), in this case \(a_j = s_j-(k-q)+1\) for \(j \geq j_0\), and the list \(A\) is
\[
A = (1, \ldots, i_0 - 1, s_{j_0}-(k-q)+1, \ldots, s_q).
\]
Thus, the \(C\)-equation associated to \(A\) and \(B\) is
\[
\sum_{i=a_{j_0}+1}^{a_{j_0}+1-1} p_{A,i}(C) \langle Y, B, i \rangle + \sum_{i=a_{j_0}+1}^{a_{j_0}+2-1} p_{A,i}(C) \langle Y, B, i \rangle + \cdots + \sum_{i=a_{k-1}+1}^{n} p_{A,i}(C) \langle Y, B, i \rangle = 0, \quad (16)
\]
where the summation can be empty if two sign flips are successive. The LHS is a sum of terms all nonnegative (or all nonpositive). Indeed, since \(a_j\) corresponds to the position of a sign flip for \(j \geq j_0\), the twistor coordinates \(\langle Y, B, i \rangle\) for \(i \in ]a_j, a_{j+1}[\) and \(j \geq j_0\) are all nonnegative (resp. all nonpositive). Moreover, the twistor coordinates \(\langle Y, B, i \rangle\) for \(i \in ]a_{j+1}, a_{j+2}[\) and for \(i \in ]a_{j-1}, a_j[\) are all nonpositive (resp. all nonnegative). Since all the minors of \(C\) are positive, the sign coming from the antisymmetry of the determinant \(p_{A,i}(C)\) exactly compensates the change of sign of the twistor coordinates. Thus all the terms of the LHS of Eq. (16) vanish, and since the Plücker coordinates of \(C\) are nonzero, we obtain
\[
\langle Y, B, i \rangle = 0, \quad \text{for} \quad i \in [n] \setminus A.
\]
Then, fix \(j_0 \in [n] \setminus A\). For each \(a \in A\), we define the list \(\tilde{A}\) from \(A\) by first replacing \(a\) by \(j_0\) and then sorting the list in ascending order. The \(C\)-equation associated to \(\tilde{A}\) and \(B\) reads
\[
p_{\tilde{A},a}(C) \langle Y, B, a \rangle = 0.
\]
Since \(p_{\tilde{A},a}(C) \neq 0\), we deduce that \(\langle Y, B, a \rangle = 0\) for \(a \in A\). Thus \((\langle Y, B, i \rangle)_{i \in [n]}\) is a list of zeros.

**Step 2.** In this step we use the \(Z\) equations and the positivity of the minors of \(Z\), to show that the list \((\langle Y, B, i \rangle)_{i \in [n]}\) changes sign at most \(k\) times.

Suppose \((\langle Y, B, i \rangle)_{i \in [n]}\) changes \(q\) times of sign with \(q > k\). Denote by \(S = (s_1 < \cdots < s_q)\) the position of the sign flips.

There are three cases to consider.
Case 1. If $q \geq k + m + 1$. Define $A = (s_1, \ldots, s_{k+m+1})$. The $Z$-equation associated to $A$ and $B$ is
\[
\sum_{i \in A} (-1)^{#i} p_{A\setminus i} (W) \langle Y, B, i \rangle = 0. \tag{17}
\]
When $i$ goes through the list $A$, the sign of $\langle Y, B, i \rangle$ flips at each element of $A$, however this change of sign is compensated by $(-1)^{#i}$. Since the matrix $Z$, and hence $W$, has positive maximal minors, the terms of the sum in the LHS of Eq (17) are all of the same sign and hence they all vanish. Since the Plücker coordinates of $W$ are nonzero, we obtain
\[
\langle Y, B, a \rangle = 0, \quad \text{for } a \in A.
\]

Then, let $j \in [n] \setminus A$. Define $\tilde{A}$ from $A$ by replacing $a_1$ by $j$ and then sorting the list in ascending order. The $Z$-equation associated to $\tilde{A}$ and $B$ reads (up to a sign)
\[
p_{A\setminus j} (W) \langle Y, B, j \rangle = 0,
\]
and we deduce that $\langle Y, B, j \rangle = 0$ by the positivity of $W$. By doing the same reasoning for the other elements $j$ in $[n] \setminus A$, we obtain that the list $(\langle Y, B, i \rangle)_{i \in [n]}$ is a list of zeros. This contradicts $q > k$.

Case 2. If $q < k + m + 1$ and the difference $k + m + 1 - q$ is even. Define the set $A$ to be the union of
- the set $\{s_1, \ldots, s_q\}$, with
- a set obtained by the union of $\frac{m-(q-k)}{2}$ pairs of elements $\{b_i, b_i + 1\}$ from $B$.

The choice of pairs does not matter, as long as the resulting $A$ is of size $k + m + 1$. We apply the $Z$-equation associated to $A$ and $B$ and obtain a sum of terms all nonnegative or all nonpositive. Indeed, when we choose the index $i$ in $A$ to be an element of a pair of elements of $B$, the twistor coordinate $\langle Y, B, i \rangle$ vanishes so the terms corresponding to elements of $B$ do not contribute to the sum. Moreover, since these elements of $B$ come by pair of successive elements, the sign $(-1)^{#i}$ still compensate the sign flips of the twistor coordinates at the elements $\{s_1, \ldots, s_q\}$ of $A$.

With the same reasoning than in case 1 we obtain that the list $(\langle Y, B, i \rangle)_{i \in [n]}$ is a list of zeros, contradicting the assumption $q > k$.

Case 3. If $q < k + m + 1$ and the difference $k + m + 1 - q$ is odd. Define the set $A$ to be the union of
- the set $\{s_1, \ldots, s_q\}$, with
- the one element set $\{\min (B^c)\}$, where $B^c$ is the complement of $B$ in $[n]$, and with
• a set obtained by the union of \( \frac{m-(q-k)}{2} \) pairs of elements \( \{b_i, b_i+1\} \) from \( B \).

Again the choice of pairs does not matter, as long as \( |A| = k + m + 1 \). We apply the \( Z \)-equation associated to \( A \) and \( B \). Once again, this is a list of terms all nonnegative or all nonpositive. Indeed, the elements of \( B \) do not contribute to the sum since the twistor coordinates vanish. Moreover, when the index \( i \) goes through the list \( (\min(B^c), s_1, \ldots, s_q) \), the sign of the twistor coordinate \( \langle Y, B, i \rangle \) flips at each element and this sign is compensated by \((-1)^{\#i}\) (again, this sign is not affected by the \( B \) elements since they come by pairs of successive elements).

We proceed in the same way as in case 1 and 2 to obtain the contradiction.

\[ \square \]

**Remark 3.7.** The assertion and proof of Step 1 is actually valid in a more general context: \( B \) can be any element of \( \binom{[n]}{m-1} \), but in this case \((\langle Y, B, i \rangle)_{i \in [n]}\) can also be a list of zeros.

**Remark 3.8.** The assertion and proof of Step 2 is still correct for \( Y \in \text{Gr}_{k,k+m} \). Indeed, we do not use the positivity of \( C \) in the proof (or in the proof of the \( Z \)-equations) and any element of \( Y \in \text{Gr}_{k,k+m} \) can be written \( Y = \tilde{C} Z \) for \( \tilde{C} \in \text{Gr}_{k,n} \).

### 3.2.2 Proving Proposition 3.4

We begin by the first statement. According to Lemma 3.5, the list \((\langle Y, B, i \rangle)_{i \in [n]}\) has exactly \( k \) sign flips. Denote by \( S = (s_1 < \cdots < s_k) \) the positions of the sign flips, defined as in the proof of Lemma 3.5. We define the set \( A \) of size \( k + m + 1 \) to be the union of \( S, B \) and \( \{i_0^+, i_0^-\} \), where \( i_0 \) is as in the statement of the proposition. The \( Z \)-equation associated to \( A \) and \( B \) is

\[
\sum_{i \in A} (-1)^{\#i} p_{A \setminus i}(W) \langle Y, B, i \rangle = 0.
\]

We now justify that all the terms of the sum are nonnegative or all nonpositive. Since the matrix \( Z \), and hence \( W \), is positive, the Plücker coordinates \( p_{A \setminus i}(W) \) have a constant sign for \( i \in A \). We show that the change of sign \((-1)^{\#i}\) exactly compensates the change of sign of \( \langle Y, B, i \rangle \). First, by definition of \( i_0^-, i_0^+ \) the twistor coordinates \( \langle Y, B, i \rangle \) for \( i \in [i_0^-, i_0^+] \) are all nonnegative or all nonpositive. Thus, \([i_0^-, i_0^+]\) is contained between two successive sign flips, say \( s_j \) and \( s_{j+1} \). More precisely, we have \([i_0^-, i_0^+] \subset [s_j, s_{j+1}] \) with \( \text{sign}(s_j) = \text{sign}(i_0^-) = \text{sign}(i_0^+) \). Since \( \langle Y, B, i \rangle = 0 \) for \( i \in B \), we deduce that when \( i \) goes through \( A \), the sign of \( \langle Y, B, i \rangle \) only changes at \( i = s_1, \ldots, s_k \). Moreover, between two successive sign flips, there always are an even number of elements of \( A \); it can be pairs of successive elements of \( B \) or the pair \((i_0^-, i_0^+)\). Hence the terms on the LHS of the \( Z \)-equation are all nonnegative or all nonpositive. Thus, they all vanish. Moreover, by the positivity of \( W \), the Plücker coordinates of \( W \) are nonzero and we deduce that

\[
\langle Y, B, a \rangle = 0, \quad \text{for } a \in A.
\]

Once again, we modify the elements of \( A \) one by one; let \( j \in [n] \setminus A \) and define \( \tilde{A} \) from \( A \) by first replacing a given element \( a \in A \) by \( j \) and then sorting the list in ascending order.
Then, the \( Z \)-equation associated to \( \tilde{A} \) and \( B \) reads (up to a sign)
\[
p_{A\setminus j}(W) \langle Y, B, j \rangle = 0.
\]

Then, simplifying by the nonzero Plücker coordinate, we obtain \( \langle Y, B, j \rangle = 0 \). Thus, \( \langle (Y, B, i) \rangle_{i\in[p]} \) is a list of zeros, this contradicts \( \langle Y, B, i_0^- \rangle \neq 0 \).

We now prove the second statement. Denote by \( i_0 \) and \( i_0 + 1 \) the positions of two of the consecutive zeros and by \( S = (s_1 < \cdots < s_k) \) the positions of the sign flips. Similarly to the previous item, we use the \( Z \) equation with \( A = S \cup B \cup \{i_0, i + 1\} \) and deduce that \( \langle (Y, B, i) \rangle_{i\in[p]} \) is the zero list. This is impossible by the strict coarse boundary conditions given in Eq. (2).

### 3.3 Properties of simplices containing the origin of \( V_Y \)

The purpose of this section is to use the constraints on the twistor coordinates obtained in the previous section to exclude some configurations of simplices containing the origin \( \pi_Y(Y) \) of the quotient space \( V_Y = \mathbb{R}^{k+m}/Y \) defined in Section 1.6. The first two sections introduce some terminology for cells and vertices. Then, in Section 3.3.3, we obtain two fundamental lemmas describing the behavior of the simplices containing the origin. At this stage, we give an idea of the proof of Theorem 2 in a simplified context. After some preparation lemmas in Section 3.3.4, we establish a refined version of these lemmas in Section 3.3.5 which describes the configuration of cells around a cell containing the origin.

**Abuse of terminology.** In the following, we will only use simplices involved in the count of the crossing number, that is simplices of type
\[
S(i_1, i_1 + 1, \ldots, i_r, i_r + 1),
\]
for \( (i_1, i_1 + 1, \ldots, i_r, i_r + 1) \) a list of strictly ascending integers between 1 and \( n \). The terminology simplex will only refer to these simplices.

#### 3.3.1 Cells terminology

**Definition 3.9** (Descendants and ancestors cells. Lineage). Let \( \mathcal{C} \) be a cell as defined in Section 1.6, it is uniquely associated to the set \( I \) of indices of its vertices. A *descendant* of \( \mathcal{C} \) is a cell associated to a strict subset of \( I \). Let \( S \) be a simplex, a descendant of \( S \) is a descendant of the \( m \)-cell of \( S \).

A cell \( \mathcal{C}' \) is an *ancestor* of \( \mathcal{C} \) if \( \mathcal{C} \) is a descendant of \( \mathcal{C}' \). A simplex \( S \) is an *ancestor* of \( \mathcal{C} \) if \( \mathcal{C} \) is a descendant of \( S \).

Two cells belong the same *lineage* if one cell is a descendant of the other.

**Notation 3.10.** Let \( \mathcal{C} \) be a cell. The list cells in the lineage of \( \mathcal{C} \) is denoted by \( L_{\mathcal{C}} \). The list of simplices which are ancestors of \( \mathcal{C} \) is denoted by \( S_{\mathcal{C}} \).
Definition 3.11 (Boundary cells. Internal cells). A boundary cell is either

- the cell \( C(1, i_1, i_1 + 1 \ldots , i_{r-1}, i_{r-1} + 1) \), where \( (1, i_1 + 1 \ldots , i_{r-1}, i_{r-1} + 1) \) is a list of strictly ascending integers smaller than \( n \), or

- the cell \( C(i_1, i_1 + 1 \ldots , i_{r-1}, i_{r-1} + 1, n) \), where \( (i_1, i_1 + 1 \ldots , i_{r-1}, i_{r-1} + 1, n) \) is a list of strictly ascending integers greater than 1, or

- a descendant of one of these cells.

An internal cell is a cell which is not a boundary cell.

It follows from the coarse boundary conditions, Eq. (2), that if \( Y \in A_{n,k,m}^o \), then the origin \( \pi_Y(Y) \) cannot belong to a boundary cell. Hence the crossing number counts the number of internal cells containing the origin of \( V_Y \).

Example 3.12. In \( m = 3 \), the vertex \( Z_i \) is a boundary cell, the cell \( C(i, i + 1) \) is a boundary cell and the cell \( C(i, j) \), with \( j > i + 1 \), is an internal cell.

3.3.2 Conjugate vertex

Lemma 3.13. Let \( S(I, i) \), with \( I \subset \binom{[n]}{m} \) and \( i \in [n] \), be an ancestor simplex to an internal \( (m-1) \)-cell \( C(I) \). Then, there exists a unique index \( \bar{i} \neq i \) such that \( S(I, \bar{i}) \) is an ancestor simplex of \( C(I) \).

Notation 3.14. When \( Z \) and \( Y \) are understood, the vertex \( i \) refers to the vertex \( Z_i \).

Definition 3.15 (Conjugate vertex). The vertex \( \bar{i} \) is called the conjugate vertex of \( i \) relative to the simplex \( S(I, i) \).

Example 3.16. In Figure 1, the conjugate vertex of \( i \) relative to \( S(i, i + 1, j, j + 1) \) is \( \bar{i} = i + 2 \).

Proof. We first relabel the simplices of \( S(I, i) \) by pairs of consecutive indices: let \( j_1, \ldots , j_r \) in \([n]\) such that \( \{j_1, j_1 + 1 \ldots , j_r, j_r + 1\} = I \cup \{i\} \).

- If \( i = j_a \) for \( 1 \leq a \leq r \). Then

\[
\bar{i} := \min \{I^c \cap \{j_a + 2, \ldots , n\}\},
\]

where \( I^c \) is the complement of \( I \) in \([n]\), is the conjugate vertex to \( i \) relative to \( S(I, i) \).

Indeed, first \( \bar{i} \) exists since \( C(I) \) is an internal cell. Then, \( S(I, \bar{i}) \) is a simplex: for any \( 1 \leq a \leq r \), introduce

\[
k_a := j_a + 1 \quad \text{if} \quad j_a \in [i, \bar{i}],
\]

\[
k_a := j_a \quad \text{otherwise},
\]

then \( \{k_1, k_1 + 1, \ldots , k_r, k_r + 1\} \) are the indices of vertices of \( S(I, \bar{i}) \). Finally, no other simplex can be an ancestor of \( C(I) \) since it is a \((m-1)\)-cell, hence \( \bar{i} \) is unique.
• If \( i = j_a + 1 \) for \( 1 \leq a \leq r \). Then

\[
\tilde{i} := \max (\{1, \ldots, i_a - 1\} \cap I^c)
\]

is, for similar reasons, the conjugate vertex to \( i \) relative to \( S(I, i) \).

\[\square\]

### 3.3.3 First properties of simplices containing the origin of \( V_Y \)

The purpose of the section is to deduce from the constraints on the twistor coordinates obtained in Section 3.2 two properties of the simplices containing the origin. From these two property we can already understand why the crossing is constant in \( \mathcal{A}_{n,k,m}^c \) as explained at the end of the section.

**Lemma 3.17** (Full dimensional simplex). Let \( Y \in \mathcal{A}_{n,k,m}^c \). Each simplex with a cell containing \( \pi_Y(Y) \) is full dimensional.

In particular, for an element \( Y \in \mathcal{A}_{n,k,m}^c \) the crossing number corresponds to the number of simplices containing the origin \( \pi_Y(Y) \) with the convention that if \( \pi_Y(Y) \) is in a cell belonging several simplices, it is counted once.

**Proof.** Suppose that \( S(i_1, i_1 + 1, \ldots, i_r, i_r + 1) \) is a flat simplex containing the origin \( \pi_Y(Y) \). Then, by Remark 1.7, for any list \( L \) of \( m \) elements of \( \{i_1, i_1 + 1, \ldots, i_r, i_r + 1\} \), we have \( \langle Y, L \rangle = 0 \). In particular, let \( B = (i_1, i_1 + 1, \ldots, i_{r-1}, i_{r-1} + 1) \), then

\[
\langle Y, B, i_r \rangle = 0 = \langle Y, B, i_{r-1} + 1 \rangle.
\]

This is forbidden by the second assertion of Lemma 3.4.

Let \( \mathcal{C} \) be a \((m-1)\) internal cell. Denote by \( I \) the list of indices of vertices of \( \mathcal{C} \). Then by Lemma 3.13, \( \mathcal{C} \) is a descendant cell of exactly two simplices \( S(I, i) \) and \( S(I, \bar{i}) \), for some \( i \in [n] \). Furthermore, the hyperplane \( H_\mathcal{C} \) containing \( \mathcal{C} \) divides \( V_Y \) into two open half spaces.

**Lemma 3.18** (Main lemma). Let \( Y \in \mathcal{A}_{n,k,m}^c \). If \( \pi_Y(Y) \) is contained in \( \mathcal{C} \) or a descendant of \( \mathcal{C} \), then \( Z_i \) and \( Z_\bar{i} \) must belong to different open half spaces relative to \( H_\mathcal{C} \).

An example of configurations of simplices for \( m = 3 \) is given in Figure 1. In this example \( I = \{i + 1, j, j + 2\} \) and \( \tilde{i} = i + 2 \). If the origin belongs to \( \mathcal{C}(i + 1, j, j + 1) \) or a descendant of this cell (in red on the figures), then the simplices can only be in the configuration of Figure 1b.

Suppose the origin \( \pi_Y(Y) \) belongs to the cell \( \mathcal{C}(i + 1, j, j + 1) \). When \( Y \) moves continuously in \( \mathcal{A}_{n,k,m}^c \), then the points \( Z_i = \pi_Y(Z_i) \) for \( 1 \leq i \leq n \) move continuously. If the configuration of Figure 1a was allowed, then after a small modification of \( Y \), the crossing number could jump by \( +1 \) if the origin jumps into the two cells \( \mathcal{C}(i, i + 1, j, j + 1) \) and \( \mathcal{C}(i + 1, i + 2, j, j + 1) \), or by \(-1 \) if the origin jumps out of any cell of the two simplices. This bad behavior of the crossing number does not happen in the configuration of Figure 1b. More
Figure 1: Two configurations of the simplices $S(i, i + 1, j, j + 1)$ and $S(i + 1, i + 2, j, j + 1)$ ancestors of the cell $C(i + 1, j, j + 1)$ in $m = 3$. In Figure 1a, the vertices $i$ and $i + 2$ belong to the same side of the plan generated the cell $C(i + 1, j, j + 1)$; in Figure 1b these vertices belong to different sides.

Generally, we prove in this way that if $\pi_Y(Y)$ avoids cells of codimension 2 or more, then the crossing number is constant in $A_{n,k,m}^o$. The rest of the Section 3.3 is devoted to making this argument correct if $\pi_Y(Y)$ belongs to any internal cell. To do so, we will only use the main lemma and the lemma about full dimensional simplices.

**Proof.** First $Z_i$ (resp. $\bar{Z}_i$) cannot belong to $H_C$, otherwise the simplex $S(I, i)$ (resp. $S(I, \bar{i})$) ancestor of $C$ is not full dimensional, this is forbidden by Lemma 3.17.

Now, suppose that $Z_i$ and $\bar{Z}_i$ belong to the same open half space with respect to $H_C$. Say $i < \bar{i}$, it follows from the construction of the conjugate vertex in Lemma 3.13 that $[i + 1, \bar{i} - 1] \cap I$ is non empty. Pick $i_0$ in this sequence and define $B = I \setminus \{i_0\}$. Since $\pi_Y(Y)$ belongs to $H_C$, we have

$$\langle Y, B, i_0 \rangle = 0.$$ 

Moreover, since $Z_i$ and $\bar{Z}_i$ belongs to the same open half space wit respect to $H_C$, we have

$$\text{sign } ((Y, B, i)) = \text{sign } ((Y, B, \bar{i})) \neq 0.$$ 

But this situation is impossible according to Proposition 3.4 (with $i^-_0 = i$ and $i^+_0 = \bar{i}$). The situation is similar for $\bar{i} < i$. This proves the lemma.

### 3.3.4 Ancestors simplices of an internal cell

The goal of this section is to prove the following proposition which describes the ancestors simplices of an internal cell in terms of one simplex and its conjugate vertices. This proposition will only be used for the proof of the main proposition of the next section.

**Proposition 3.19.** Let $C$ be an internal cell of dimension $d < m$, and let $I = (i_0, \ldots, i_d)$ be the set of indices of its vertices. Let $j_1, j_2, \ldots, j_{m-d}$ in $[n]$ such that $S(I, j_1, j_2, \ldots, j_{m-d})$ is an ancestor simplex of $C$. Introduce, for each $1 \leq a \leq m - d$, the conjugate vertex $\bar{j}_a$ of $j_a$ relative...
to $S(I, j_1, j_2, \ldots, j_{m-d})$. Then, for each choice of $(\alpha_1, \ldots, \alpha_{m-d})$ in $(j_1, j_1+1) \times \cdots \times (j_{m-d}, j_{m-d}+1)$ such that the elements of $(\alpha_1, \ldots, \alpha_{m-d})$ are all pairwise distinct, the simplex

$$S(I, \alpha_1, \ldots, \alpha_{m-d})$$

is an ancestor simplex of $C$, moreover each simplex ancestor of $C$ is obtained in this way.

To prove this proposition, we first establish two lemmas which can be safely forgotten once the proposition is proved. We use the notations of Proposition 3.19 for these two lemmas.

We first introduce the following terminology. Let $S$ be a simplex. Its vertices are partitioned into $r$ couples with consecutive indices. Each couple is called a pair of vertices of $S$, and the corresponding couple of indices is called a pair of indices of $S$. The following lemma explains how indices of an internal cell $C$ can be paired in an ancestor of $C$.

**Lemma 3.20.** Let $C$ be an internal cell. Let $L = (i_a, \ldots, i_b)$, with $0 \leq a \leq b \leq d$, be a sequence of consecutive isolated indices of $C$ (i.e. the vertex $i_a - 1$ and the vertex $i_b + 1$ are not vertices of $C$). Then,

1. if the length of $L$ is odd, the vertices of $L$ can appear paired into two different way in a simplex of $S_C$:
   (a) the vertex $i_a$ is paired with the vertex $i_a - 1$ and the rest of the simplices of $L$ are paired together,
   (b) the vertex $i_b$ is paired with $i_b + 1$ and the rest of the simplices are paired together,

2. if the length of this sequence is even, then in any simplex of $S_C$ the vertices of $(i_a, \ldots, i_b)$ are paired together, i.e. $i_a$ with $i_a + 1$, $i_{a+1}$ with $i_{a+1} + 1$ ...

**Proof.** The first assertion follows from the definition of a simplex. We prove the second assertion by contradiction: suppose $S$ is an ancestor simplex of $C$ and suppose that the pairings of the indices of $S$ containing an element of $L$ are

$$P_1 = (i_a - 1, i_a), \ P_2 = (i_a + 1, i_a + 2), \ldots, \ P_{b-a+1} = (i_b, i_b + 1).$$

Then, let $C'$ be the $(m - 2)$-cell with the same pairings than $S$ unless $P_1, \ldots, P_{b-a}$ which are shifted by $+1$ (i.e replace $P_1$ by $(i_a, i_a + 1)$ and so on), and $P_{b-a+1}$ which is forgotten. But $C'$ is boundary cell, indeed let $J$ be the indices of the vertices of $C'$ and $J'$ its complement in $[n]$, one can add to $C'$ the vertex $\max(J')$ to obtain the cell a cell of type $C(k_1, k_1+1, \ldots, k_r, k_r + 1, n)$. Moreover $C'$ is an ancestor cell of $C$, hence $C$ is a boundary cell, this is a contradiction.

The second lemma is the following.

**Lemma 3.21.** We have that:

- the number of vertices of $C$ satisfies $d + 1 \geq r$,  

27
• the number \( n_\mathcal{C} \) of sequences of isolated indices of odd length in \( I \) is exactly \( 2r - (d + 1) = m - d \).

**Proof.** First, since \( \mathcal{C} \) is an internal cell, we have \( d + 1 \geq r \). Otherwise, we can always complete the vertices of \( \mathcal{C} \) to form a boundary cell of dimension \((m - 1)\).

We then prove by induction on the number of vertices \( d + 1 \) of \( \mathcal{C} \) that \( n_\mathcal{C} = 2r - (d + 1) \).

**Initialization** \( d + 1 = r \). If \( n_\mathcal{C} > 2r - (d + 1) = r \), then \( \mathcal{C} \) cannot be a descendant of a simplex because a simplex contains maximum \( r \) couples of isolated indices. If \( n_\mathcal{C} < r \), then two indices of \( I \) are consecutive and \( \mathcal{C} \) has \( r \) vertices but in this case it is easy to verify that \( \mathcal{C} \) cannot be an internal cell.

**Heredity** \( d + 1 > r \). Suppose that \( n_\mathcal{C} \) is greater (reps. lower) than \( 2r - (d + 1) \). Then pick one odd sequence of consecutive indices and select the maximal index of this sequence. Remove the vertex of \( \mathcal{C} \) corresponding to this index and denote by \( \mathcal{C}' \) the corresponding cell. Since \( \mathcal{C} \) is an internal cell with \( (d + 1) \) vertices, then \( \mathcal{C}' \) is an internal cell with \( d \) vertices. Moreover \( n_{\mathcal{C}'} = n_\mathcal{C} - 1 \) is greater (resp. lower) than \( 2r - s - 1 \), but this is impossible by induction.

We now prove the proposition.

**Proof of Proposition 3.19.** We deduce from these two lemmas that that since

\[ S(I, j_1, j_2, \ldots, j_{m-d}) \]

is an ancestor simplex of \( \mathcal{C} \), then each sequence of isolated indices of odd length of \( \mathcal{C} \) is followed or preceded by \( j_a \) for \( 1 \leq a \leq m - d \). Moreover \( \bar{j}_a \) is, by construction, the predecessor or successor of this same sequence. It is then a consequence of of Lemma 3.20 that a simplex is ancestor of \( \mathcal{C} \) if and only if it is associated to the vertices \((I, \alpha_1, \ldots, \alpha_{m-d})\) for a choice of \( \alpha_1, \ldots, \alpha_{m-d} \) in \((j_1, \bar{j}_1) \times \cdots \times (j_{m-d}, \bar{j}_{m-d})\) pairwise disjoints.

### 3.3.5 Configuration of cells in the lineage of a cell containing the origin

The following proposition explains how cells in the lineage of a cell \( \mathcal{C} \) containing the origin of \( V_Y \) “triangulate” a neighborhood of \( \mathcal{C} \), i.e. cells are pairwise distinct and they cover a neighborhood of \( \mathcal{C} \). We recall that \( L_\mathcal{C} \) is the list of cells in the lineage of \( \mathcal{C} \) and \( S_\mathcal{C} \) the set of ancestors simplices of \( \mathcal{C} \). Let \( U_\mathcal{C} \) the set of points of the cells in \( \{\mathcal{C}\} \cup L_\mathcal{C} \) in \( \mathbb{R}^n \).

**Proposition 3.22** (Configuration of adjacent cells). Let \( Y \in A_{n,k,m}^0 \). Let \( \mathcal{C} \) be a cell containing \( \pi_Y(Y) \). Then,

1. the set \( U_\mathcal{C} \) is a neighborhood of \( \mathcal{C} \),
2. each point of \( U_\mathcal{C} \) belongs to a unique cell of \( L_\mathcal{C} \).
Example 3.23. Suppose $\mathcal{C} = \mathcal{C}(i, j)$ with $j > i + 2$ and $m = 3$. Then $\mathcal{C}$ is a descendant of 4 simplices and the interior of each simplex is in the lineage of $\mathcal{C}$. Following Lemma 3.22, the interior of these 4 simplices cannot intersect. These 4 simplices must be in the configuration of Figure 2.

![Figure 2: Configuration of the 4 simplices ancestors to a cell $\mathcal{C}(i, j)$ containing the origin when $j > i + 2$ and $m = 3.$](image)

In particular, it follows from this lemma that for small and continuous modification of $Y$, the number of cells of $L_{\mathcal{C}}$ containing $\pi_Y(Y)$ is one.

The rest of this section is devoted to the proof of this Proposition. We begin by the proof of second assertion.

The case $\dim(\mathcal{C}) = m$. If $\dim(\mathcal{C}) = m$, then the simplex $S$ ancestor of $\mathcal{C}$ is full dimensional and the cells $\{\mathcal{C}\} \cup L_{\mathcal{C}}$ are the cells of $S$. In particular, they form a neighborhood of $\mathcal{C}$ and they cannot pairwise intersect otherwise $S$ is flatten and this is forbidden by Lemma 3.17.

Proving assertion 2 when $\dim(\mathcal{C}) < m$. The cell $\mathcal{C}$ is an internal cell since $\pi_Y(Y)$ belongs to $\mathcal{C}$. We prove that two cells of $L_{\mathcal{C}}$ cannot intersect. Suppose that $\mathcal{C}_1$ and $\mathcal{C}_2$ are two cells of $L_{\mathcal{C}}$ with a common point, then $\mathcal{C}_1$ and $\mathcal{C}_2$ cannot belong to the same simplex, otherwise this simplex is flatten and this is forbidden by Lemma 3.17. Hence $\mathcal{C}_1$ and $\mathcal{C}_2$ are descendants of two different simplices of $S_{\mathcal{C}}$. Hence, proving that $\mathcal{C}_1$ and $\mathcal{C}_2$ cannot intersect is equivalent to the next lemma.

Definition 3.24. Let $L$ be the list of common descendants vertices of $S_1$ and $S_2$. The simplices $S_1$ and $S_2$ intersect trivially if $S_1 \cap S_2$ is covered by descendants cells of $S_1$ and $S_2$.

For example, the two simplices of the main lemma can only intersect trivially.

Lemma 3.25. Two simplices of $S_{\mathcal{C}}$ can only intersect trivially.

Proof. Suppose $\mathcal{C}$ is of dimension $d$. Let $1 \leq a \leq m - d$, we prove by induction on $a$ that: each couple $(S, S')$ of simplices of $S_{\mathcal{C}}$ with $m + 1 - a$ common vertices can only intersect trivially. Note that $S$ and $S'$ cannot have more than $m - d + 1$ common vertices since they are not ancestors of $\mathcal{C}$.
Initialization. If \( a = 1 \), then \( S \) and \( S' \) intersect trivially by the main lemma.

**Herediticity.** Let \( a \) with \( 1 \leq a \leq m - d \). Let \( S \) and \( S' \) be two simplices of \( S_\mathcal{E} \) sharing exactly \( m + 1 - a \) vertices, and let \( L \) be the list of indices of these vertices. Let \( (L, i_1, \ldots, i_a) \) be the list of indices of vertices of \( S \). Denote by \( i_j \), for \( 1 \leq j \leq a \), the conjugate vertex of \( i_j \) relative to \( S \). It follows from Proposition 3.19 that the list of vertices of \( S' \) is \( (L, \tilde{i}_1, \ldots, \tilde{i}_a) \).

Let \( p : \mathbb{R}^m \to \mathbb{R}^a \) be the projection relative to the vector space \( \text{Span} (Z_i, \text{for } i \in L) \). We associate to any simplex \( S (\tilde{L}, \alpha_1, \ldots, \alpha_a) \) of \( S_\mathcal{E} \), where \( \alpha_j \in \{i_j, \tilde{i}_j\} \), the \( a \)-dimensional convex cone

\[
\mathcal{C} (\alpha_1, \ldots, \alpha_a) = \text{Span}_{\geq 0} (p (Z_{\alpha_1}), \ldots, p (Z_{\alpha_a})) \subset \mathbb{R}^a,
\]

where \( \text{Span}_{\geq 0} (p (Z_{\alpha_1}), \ldots, p (Z_{\alpha_a})) \) denotes the set of linear combinations of \( p (Z_{\alpha_1}), \ldots, p (Z_{\alpha_a}) \) with nonnegative coefficients. A point \( p (Z_{\alpha_i}) \) of \( \mathcal{C} (\alpha_1, \ldots, \alpha_a) \) is called a vertex of index \( \alpha_j \).

Then, we replace the study of intersection of simplices by the study of intersection of cones. We have that two simplices of \( S_\mathcal{E} \) intersect if and only if their corresponding cones intersect. We define the trivial intersection of cones by: two cones \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \), with \( \tilde{L} \) the list of indices of their common vertices, intersect trivially if \( \mathcal{C}_1 \cap \mathcal{C}_2 = \text{Span}_{\geq 0} (p (Z_i), \text{for } i \in \tilde{L}) \). Then, two simplices intersect trivially if and only of their corresponding cones intersect trivially. Finally, since each simplex of \( S_\mathcal{E} \) is full dimensional (Lemma 3.17), its corresponding cone is \( a \)-dimensional.

**Claim 3.26.** The cone \( \mathcal{C} (i_1, \ldots, i_a) \) (resp. \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \)) cannot contain a vertex of \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \) (resp. \( \mathcal{C} (i_1, \ldots, i_a) \)).

Indeed, suppose \( p (Z_{i_j}) \) belongs to \( \mathcal{C} (i_1, \ldots, i_a) \), for \( 1 \leq j \leq a \). Then the cone \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_j, \ldots, \tilde{i}_a, i_j) \) can either be of dimension strictly lower than \( a \) or it intersects non trivially with \( \mathcal{C} (i_1, \ldots, i_a) \). Both case are forbidden, the first one because the corresponding simplex would be flat and the second one because \( S (\tilde{L}, \tilde{i}_1, \ldots, \tilde{i}_a) \) and \( S (\tilde{i}_1, \ldots, \tilde{i}_j, \ldots, \tilde{i}_a, i_j) \) would intersect non trivially, this is forbidden by the induction hypothesis.

Let \( x \in \mathcal{C} (i_1, \ldots, i_a) \cap \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \) and suppose \( x \) is not the origin. Since \( \mathcal{C} (i_1, \ldots, i_a) \) is convex, the segment \( [p (Z_{i_1}), x] \) is contained in \( \mathcal{C} (i_1, \ldots, i_a) \). It follows from Claim 3.26 that the segment \( [p (Z_{i_1}), x] \) cannot be contained in \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \), otherwise \( p (Z_{i_1}) \in \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \). Thus, there is at least a point \( y \) in \( [p (Z_{i_1}), x] \) belonging to the boundary of \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \). Then \( y \) belongs to at least a codimension one face of \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \), we denote by \( F \) this face. Let \( \tilde{I} \) be the set of indices of the verticies generating \( F \), i.e. \( F = \text{Span}_{\geq 0} (p (Z_i), \tilde{i} \in \tilde{I}) \). Let \( \tilde{i}_j \), for \( 1 \leq j \leq a \), be the index such that \( \{\tilde{i}_1, \ldots, \tilde{i}_a\} = \tilde{I} \cup \{\tilde{i}_j\} \). Then \( \mathcal{C} (i_1, \ldots, i_a) \) and \( \mathcal{C} (\tilde{I}, \tilde{i}_j) \) intersect in \( y \). Moreover, this intersection is non trivial otherwise \( y \in \text{Span}_{\geq 0} (p (Z_{i_j})) \), but then \( p (Z_{i_j}) \) belongs to \( \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) \), this is forbidden by Claim 3.26. The non trivial intersection of \( \mathcal{C} (i_1, \ldots, i_a) \) and \( \mathcal{C} (\tilde{I}, \tilde{i}_j) \) is forbidden by the induction hypothesis. Hence \( \mathcal{C} (i_1, \ldots, i_a) \cap \mathcal{C} (\tilde{i}_1, \ldots, \tilde{i}_a) = \{0\} \), that is their intersection is trivial. This ends the proof of the induction and thus of assertion 2.

\( \square \)
Proving assertion 1 when \( \dim(\mathcal{C}) < m \). Suppose \( \mathcal{C} \) is of dimension \( d \) and let \( I \) be the set of indices of the vertices of \( \mathcal{C} \). Let \( p_\mathcal{C} : \mathbb{R}^m \to \mathbb{R}^{m-d} \) be the projection relative to the \( d \)-plan containing \( \mathcal{C} \), i.e. \( \text{Span}(p(Z_i), i \in I) \). To prove that \( U_\mathcal{C} \) is a neighborhood of \( \mathcal{C} \), it suffices to prove that \( p_\mathcal{C}(U_\mathcal{C}) = \bigcup_{S_i \in S_\mathcal{C}} p_\mathcal{C}(S_i) \) covers \( \mathbb{R}^{m-d} \). We prove that \( p_\mathcal{C}(U_\mathcal{C}) \) has no boundary. Since two cones intersect trivially, when a point leaves a cone by a unique face it lands in the conjugate cone relative to this face. Hence the dimension of the boundary of \( p_\mathcal{C}(U_\mathcal{C}) \) is less or equal to \( m - d - 2 \), but \( p_\mathcal{C}(U_\mathcal{C}) \) is a finite union of \( (m - d) \)-dimensional cones so this is impossible.

3.4 Constancy of the crossing number in \( A_{n,k,m}^0 \times \text{Mat}_{n,k+m}^0 \)

Since \( \text{Gr}_{k,n}^{d>0} \) and \( \text{Mat}_{n,k+m}^{d>0} \) are path connected (see [Pos06] for the positive Grassmannian), there exists a continuous path

\[
(C, Z) : [0, 1] \to \text{Gr}_{k,n}^{d>0} \times \text{Mat}_{n,k+m}^{d>0}
\]

between any two couples of points in \( A_{n,k,m}^0 \times \text{Mat}_{n,k+m}^{d>0} \). We also denote \( Y(t) = C(t) Z(t) \). We prove that the crossing number \( c_{n,k,m}(Y(t), Z(t)) \) is constant along these paths, hence proving Theorem 2. For every \( t \in [0, 1] \), we denote by \( L(t) \) the list of cells containing the origin \( \pi_{Y(t)}(Y(t)) \) of \( V_{Y(t)} \). In the following, we prove that for any \( t_0 \in [0, 1] \), there exists \( \epsilon > 0 \) such that \( c_{n,k,m}(Y(t), Z(t)) = \text{Card}(L(t)) \) is constant for \( t \in [t_0 - \epsilon, t_0 + \epsilon] \cap [0, 1] \).

Since \( [0, 1] \) is compact, we can extract a finite number of such balls to cover it, hence we deduce that the crossing number is constant on \([0, 1] \).

**Step 1.** Fix \( t_0 \in [0, 1] \) and let \( L(t_0) = \{ \mathcal{C}_1, \ldots, \mathcal{C}_{n_0} \} \) be the list of cells containing the origin at \( t_0 \). When \((C, Z) \) moves continuously in \( A_{n,k,m}^0 \times \text{Mat}_{n,k+m}^{d>0} \), the vertices \( Z_i(t) = \pi_{Y(t)}(Z_i) \) move continuously. By applying Proposition 3.22 to \( \mathcal{C}_i \) at \( t_0 \) we deduce by continuity that there exists \( \epsilon_i \) such that for every \( t \in [t_0 - \epsilon_i, t_0 + \epsilon_i] \).

- The set \( U_{\mathcal{C}_i} \) is still a neighborhood of \( \mathcal{C}_i \),
- the cells of \( L_{\mathcal{C}_i} \) do no intersect,
- the origin \( \pi_{Y(t)}(Y(t)) \) belongs to a unique cell of \( L_{\mathcal{C}_i} \).

We denote by \( \mathcal{C}_i(t) \) the cell of \( L_{\mathcal{C}_i} \) containing the origin at time \( t \). We define such \( \epsilon_i \) for every \( 1 \leq i \leq n_0 \) and let \( \epsilon := \min \{ \epsilon_1, \ldots, \epsilon_{n_0} \} \). Hence we defined \( n_0 \) paths

\[
[t_0 - \epsilon, t_0 + \epsilon] \to \mathcal{C}_i(t)
\]

which are pairwise disjoints at \( t_0 \).
Step 2. We prove that, up to redefining $\epsilon > 0$, two paths $t \to C_i(t)$ constructed in Step 1 do not intersect on $]t_0 - \epsilon, t_0 + \epsilon[$. Let $t_i = t_i^{(1)} < t_i^{(2)} < \cdots$ be the discontinuity points of $t \to C_i(t)$ on $[t_0, t_0 + \epsilon]$. Denote by $C_i^+$ the first value of $t \to C_i(t)$ on $[t_i, t_0 + \epsilon]$ different from $C_i$. There are two cases:

- if $C_i(t_i) = C_i^+$, then $C_i$ is an ancestor cell of $C_i^+$,
- if $C_i(t_i) = C_i^-$, then $C_i$ is a descendant cell of $C_i^+$.

Fix $i \neq j$ and suppose that the paths $t \to C_i(t)$ and $t \to C_j(t)$ intersect. If these two paths intersect right after $t_0$:

- if $t_i = t_j = t_0$ and $C_i^+ = C_j^+ = C$ then $C$ is an ancestor cell of $C_i$ and of $C_j$, so $C_i$ and $C_j$ belong to the same simplex. But then, at $t_0$ the origin belongs to two cells of the same simplex, hence this simplex is flatten, this is impossible by Lemma 3.17.
- if $t_i = t_0$, $t_j > t_0$ and $C_i^+ = C_j$, then $C_i$ and $C_j$ are in the same lineage. But then at $t_0$ the origin is contained in two cells in the same lineage, this is impossible since by definition the intersection of two cells in the same lineage is empty. The situation is similar if we exchange $i$ and $j$.

In the other cases of intersection of $t \to C_i(t)$ and $t \to C_j(t)$, it suffices to shorten the interval $[t_0, t_0 + \epsilon]$ by redefining $\epsilon$ in order to avoid the intersection. By doing a similar reasoning for $t \in ]t_0 - \epsilon, t_0[$, we prove that that there exists $\epsilon > 0$ such that the paths $t \to C_i(t)$, for $1 \leq i \leq n_0$ do no intersect on $]t_0 - \epsilon, t_0 + \epsilon[$.

Step 3. We now prove that for $t \in ]t_0 - \epsilon, t_0 + \epsilon[$, we have

$$L(t) = \{C_1(t), \ldots, C_{n_0}(t)\}$$

up to redefining $\epsilon$. By Step 2 we have the inclusion $\{C_1(t), \ldots, C_{n_0}(t)\} \subseteq L(t)$. Suppose that there exists $\tilde{t}$ in $]t_0, t_0 + \epsilon[$ such that either (i) for $t \in ]t_0, \tilde{t}[$ we have $L(t) = \{C_1(t), \ldots, C_{n_0}(t)\}$ and at $t = \tilde{t}$ the origin is contained in a cell $\tilde{C}$ not in $\{C_1(t), \ldots, C_{n_0}(t)\}$ or (ii) for $t \in ]t_0, \tilde{t}[$ we have $L(t) = \{C_1(t), \ldots, C_{n_0}(t)\}$ and for $t > \tilde{t}$ small enough the origin is contained in a cell $\tilde{C}$ not in $\{C_1(t), \ldots, C_{n_0}(t)\}$. Both cases are treated in the same way.

- If $\tilde{t} > t_0$ then by redefining $\epsilon \in ]0, \tilde{t} - t_0[$, we have $L(t) = \{C_1(t), \ldots, C_{n_0}(t)\}$ on $[t_0, t_0 + \epsilon]$.
- If $\tilde{t} = t_0$, then we are in situation (ii) according to Step 1. Hence, at $t_0$ the origin is contained a descendant cell $C_i$ of $C$. This cell $C_i$ is in $L(t_0)$. By Step 1, we deduce that $\tilde{C}$ belongs to the path $t \to C_i(t)$ for $t > t_0$ close enough to $t_0$, this is a

By doing a similar reasoning for $t < t_0$, we prove that there exists $\epsilon$ such that $L(t) = \{C_1(t), \ldots, C_{n_0}(t)\}$ for $t \in ]t_0 - \epsilon, t_0 + \epsilon[$ and thus the crossing number is constant on $]t_0 - \epsilon, t_0 + \epsilon[$. This ends the proof.
3.5 Indepedence of the crossing number in \( n \)

Let \( m = 2r - 1 \) for some positive integer \( r \). We use the same approach than for the winding number. We showed that the crossing number is independent of the point in \( \text{Mat}_{n,k,m}^0 \times A_{n,k,m}^0 \). We now show that for two specific choices of couples, one in \( \text{Mat}_{n,k,m}^0 \times A_{n+1,k,m}^0 \) and the other one in \( \text{Mat}_{n,k,m}^0 \times A_{n,k+1,m}^0 \) the crossing number is the same. Thus the crossing number is independent of \( n \).

**Proposition 3.27.** There exist \((Z', Y) \in \text{Mat}_{n+1,k,m}^0 \times A_{n+1,k,m}^0 \) and \((Z, Y) \in \text{Mat}_{n,k,m}^0 \times A_{n,k,m}^0 \) such that

\[
c_{n+1,k,m}(Y, Z') = c_{n,k,m}(Y, Z).
\]

**Proof.** Let \( Z' = (Z_1, \ldots, Z_{n+1}) \in \text{Mat}_{n+1,k,m}^0 \) then \( Z = (Z_1, \ldots, Z_n) \in \text{Mat}_{n,k,m}^0 \). We first show that \( A_{n,k,m}^0 \cap A_{n+1,k,m}^0 \neq \emptyset \). Indeed, let \( C \in \text{Gr}_{k,n}^0 \) so that \( Y = C Z \in A_{n,k,m}^0 \). We define the matrix \( C' \) by adding a \((n+1)\)th column of zeros to \( C \), hence we have \( Y = C Z = C' Z' \). Then \( Y \in A_{n,k,m}^0 \cap A_{n+1,k,m}^0 \) but since \( A_{n,k,m}^0 \) is open we also have \( A_{n,k,m}^0 \cap A_{n+1,k,m}^0 \neq \emptyset \).

Then, choose \( Y_2 \) in \( A_{n,k,m}^0 \cap A_{n+1,k,m}^0 \) such that

\[
(Y_2, i_1, i_1 + 1, \ldots, i_r, i_r + 1) \neq 0,
\]

where \((i_1, i_1 + 1, \ldots, i_r, i_r + 1) \in \binom{n+1}{m} \). This is always possible since the dimension of \( A_{n,k,m}^0 \cap A_{n+1,k,m}^0 \) is \( km \) since it is an intersection of open sets, and the vanishing locus of the twistor coordinates \( \langle Y_2, i_1, i_1 + 1, \ldots, i_r, i_r + 1 \rangle = 0 \) is of codimension \( 1 \). Thus, if the origin of \( Y_2 \) is contained in a simplex, it is contained in its \( m \)-dimensional cell.

In order to prove that the crossing number \( c_{n,k,m}(Y_2, Z) \) and \( c_{n+1,k,m}(Y_2, Z') \) is the same it suffices to prove that the origin cannot belong to a cell

\[
C (i_1, i_1 + 1, \ldots, i_r - 1 + 1, n, n + 1),
\]

where \((i_1, i_1 + 1, \ldots, i_r - 1 + 1) \in \binom{n-1}{m-2} \). However such a cell contains the origin if

\[
\text{sign} \langle Y_2, i_1, i_1 + 1, \ldots, i_r - 1 + 1, n, n + 1 \rangle = -\text{sign} \langle Y_2, i_1, i_1 + 1, \ldots, i_r - 1 + 1, n, n + 1 \rangle
\]

and it follows from the strict coarse boundary conditions for \( Y_2 \in A_{n+1,k,m}^0 \) and for \( Y_2 \in A_{n,k,m}^0 \) that the LHS and RHS are positive.

3.6 The crossing number for \( n = k + m \)

Let \( m = 2r - 1 \) for some positive integer \( r \). We show that there exists \( Z \in \text{Mat}_{n,n}^0 \) and \( C \in \text{Gr}_{k,k+m}^0 \) such that the crossing number

\[
c_{n=k+m,k,m}(C Z, Z) = \begin{cases} 
2k+m-1 \binom{k+m-2}{m-1} & \text{for } k \text{ odd}, \\
2 \binom{k+m-2}{m-1} & \text{for } k \text{ even}.
\end{cases}
\]

(18)
Since we proved that the crossing number is independent of $Z, Y$ and $n$, this ends the proof of Theorem 2.

**Step 1.** Each simplex containing the origin of $V_Y$ is full dimensional by Lemma 3.17, we choose $C \in \text{Gr}^{>0}_{k,n}$ such that the origin of $V_Y$ only intersects these simplices in their interior. Equivalently, we pick $C \in \text{Gr}^{>0}_{k,n}$ such that each twistor coordinate

$$\langle CZ, i_1, i_1 + 1, \ldots, \hat{i}_j + \epsilon, \ldots, i_r, i_r + 1 \rangle,$$

for $\epsilon \in \{0,1\}$ and $(i_1, i_1 + 1, i_2, \ldots, i_r + 1) \in \binom{[n]}{m}$, this is always possible since the locus of points with one vanishing twistor coordinate is of codimension 1 in $\text{Gr}^{>0}_{k,n}$.

**Step 2.** Let $(i_1, i_1 + 1, i_2, \ldots, i_r, i_r + 1) \in \binom{[n]}{m}$, the origin belongs the simplex $S(i_1, i_1 + 1, \ldots, i_r, i_r + 1)$ if and only if it satisfies the following two conditions:

$$\text{sign} \left\langle i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1 \right\rangle = -\text{sign} \left\langle i_1, i_1 + 1, \ldots, \hat{i}_j, \ldots, i_r, i_r + 1 \right\rangle,$$

(Condition (i))

and

$$\text{sign} \left\langle i_1, i_1 + 1, \ldots, \hat{i}_j, \ldots, i_r, i_r + 1 \right\rangle$$

is independent of $j$. (Condition (ii))

Since $n = k + m$ the twistor coordinates are give by determinants of squared matrices, we have

$$\left\langle i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1 \right\rangle = \det \left( I_{i_1, i_1 + 1}, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1 \right) \det(Z),$$

where $I_{i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1}$ is the $m \times (k + m)$ matrix whose $l$th row has a 1 at the $l$th index of the list $i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r + 1$ and zeros elsewhere. Using the standard expansion of the determinant we get

$$\det \left( I_{i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1} \right) = (-1)^{k+j-\epsilon} \det \left( C_{[n]\backslash\{i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1\}} \right).$$

Hence, since $Z \in \text{Mat}^{>0}_{n,n}$ and $C \in \text{Gr}^{>0}_{k,k+m}$ we obtain

$$\text{sign} \left\langle i_1, i_1 + 1, \ldots, \hat{i}_j + 1, \ldots, i_r, i_r + 1 \right\rangle = (-1)^{s+j+\epsilon}.$$

Thus, condition (i) is always satisfied and condition (ii) is satisfied precisely if

$$i_1 = i_2 = \cdots = i_r \mod 2.$$  \hspace{1cm} (19)

Thus the crossing number is equal to the number of sequences $(i_1, \ldots, i_r)$ between 1 and $n-1$ such that $i_{j+1} > i_j + 1$ satisfying Eq. (19). This is exactly the expression of the crossing number given in Eq. (18).
