

# Trace Diagnostics for Signal-based Temporal Properties

Chaima Boufaied, Claudio Menghi, *Member, IEEE*, Domenico Bianculli, *Member, IEEE*,  
and Lionel C. Briand, *Fellow, IEEE*

**Abstract**—Trace checking is a verification technique widely used in Cyber-physical system (CPS) development, to verify whether execution traces satisfy or violate properties expressing system requirements. Often these properties characterize complex signal behaviors and are defined using domain-specific languages, such as SB-TemPsy-DSL, a pattern-based specification language for signal-based temporal properties. Most of the trace-checking tools only yield a Boolean verdict. However, when a property is violated by a trace, engineers usually inspect the trace to understand the cause of the violation; such manual diagnostic is time-consuming and error-prone. Existing approaches that complement trace-checking tools with diagnostic capabilities either produce low-level explanations that are hardly comprehensible by engineers or do not support complex signal-based temporal properties. In this paper, we propose *TD-SB-TemPsy*, a trace-diagnostic approach for properties expressed using SB-TemPsy-DSL. Given a property and a trace that violates the property, *TD-SB-TemPsy* determines the root cause of the property violation. *TD-SB-TemPsy* relies on the concepts of *violation cause*, which characterizes one of the behaviors of the system that may lead to a property violation, and *diagnoses*, which are associated with violation causes and provide additional information to help engineers understand the violation cause. As part of *TD-SB-TemPsy*, we propose a language-agnostic methodology to define violation causes and diagnoses. In our context, its application resulted in a catalog of 34 violation causes, each associated with one diagnosis, tailored to properties expressed in SB-TemPsy-DSL.

We assessed the applicability of *TD-SB-TemPsy* using an industrial case study from the satellite domain. The results show that *TD-SB-TemPsy* could finish within a timeout of 1 min for  $\approx 83.66\%$  of the trace-property combinations in our dataset, yielding a diagnosis in  $\approx 99.84\%$  of these cases; these results suggest that our tool is applicable and efficient in most cases.

## 1 INTRODUCTION

CYBER-PHYSICAL system (CPS) development requires engineers to verify whether the system meets its requirements. In industrial contexts, verification is often performed through *trace-checking* tools (e.g., [1], [2], [3], [4], [5], [6]). Engineers collect traces, sequences of records representing the behavior of the system, and use trace-checking tools to check whether the traces satisfy or violate properties expressing the system requirements. If properties are violated, the system has faults that need to be identified and corrected.

In the case of *pattern-based* trace-checking tools, properties are expressed using pattern-based languages. Pattern-based languages contain domain-specific constructs to express complex requirements [7] that increase their usability in industrial contexts [7], [8]. In this work, we consider requirements expressed in SB-TemPsy-DSL [1], a pattern-

based language that can express complex signal behaviors based on a recent taxonomy [9]. This language enables engineers to write properties describing important types of requirements for industrial CPSs, through constructs that express complex signal behaviors, such as spikes and oscillations.

When a property is checked on a trace, trace-checking tools usually provide a *Boolean verdict*: *true* if the trace satisfies the property, *false* otherwise. When the property is violated by a trace, engineers usually inspect the trace to understand the cause of the violation, leading to the analysis of a high number of records. For example, in our industrial case study in the satellite domain, the average number of records included in 361 traces is 438224. Inspecting a large number of records, and checking the causes of property violations, requires in general significant time. Additionally, this activity is error-prone and engineers may fail to identify the actual cause of the property violation. Therefore, they need automated tools that can explain the reasons leading to the violation of the properties. These tools should provide diagnostic information enabling engineers to understand the cause of violations.

Two complementary strategies were proposed in the literature to help engineers in these activities: (i) *isolating slices of traces* that explain the property violation; and (ii) checking whether traces show common *behaviors that lead to the property violation*. These two complementary strategies are discussed in the following.

- C. Boufaied is with the school of EECS, University of Ottawa, Ottawa, ON K1N 6N5, Canada (e-mail:chaima.boufaied@uottawa.ca).
- D. Bianculli is with the Interdisciplinary Centre for Security, Reliability, and Trust (SnT) of the University of Luxembourg, Luxembourg (e-mail: domenico.bianculli@uni.lu).
- C. Menghi is with McMaster University, Hamilton, Canada (e-mail: cmenghi@mcmaster.ca).
- L. Briand holds shared appointments with the Interdisciplinary Centre for Security, Reliability, and Trust (SnT) of the University of Luxembourg, Luxembourg and the school of EECS, University of Ottawa, Ottawa, ON K1N 6N5, Canada (e-mail: lionel.briand@uni.lu).

Approaches that isolate *slices of the trace* that explain the property violation (e.g., [10], [11], [12], [13]) usually assume that the properties are specified using a logical formula. To explain the property violation, these approaches iteratively analyze the sub-formulae of the logical formula and identify minimal slices of the trace that explain the satisfaction or violation of each sub-formula. Using this approach, the size of the explanation increases with the number of sub-formulae of the logical formula expressing the property. For properties expressed using pattern-based languages, which provide domain-specific constructs encoding complex logical formulae, using such an approach is likely to produce large explanations that are hardly comprehensible by engineers. Besides, none of these approaches was implemented and evaluated on realistic case studies.

Approaches that check for the presence of common behaviors leading to the property violation (e.g., [14], [15], [16]), which are assumed to correspond to common causes of such violation. Each cause therefore encodes one of the behaviors, observed in the trace, that may lead to a property violation and help explain it. However, existing approaches do not support complex signal-based temporal properties of CPS, such as the one expressed using SB-TemPsy-DSL. Besides, it is unclear how to extend these approaches to support signal-based temporal properties, since such approaches do not come with a precise methodology that describes how to add new causes that support more complex properties.

In this work, we propose *TD-SB-TemPsy*, a trace-diagnostic approach for signal-based temporal properties. *TD-SB-TemPsy* takes as input a trace and a property expressed using SB-TemPsy-DSL and violated by the trace; it provides as output an explanation that describes why the property is violated on that trace.

To detect the source of the property violation, we define the notions of *violation cause* and *diagnosis*. A violation cause characterizes one of the behaviors of the system that may lead to a property violation. For example, for a property requiring a signal to show a spike with an amplitude and a width lower than specific thresholds, the absence of any spike behavior in an increasing signal is a violation cause. Diagnoses are associated with violation causes and provide additional information to help engineers understand such causes. For example, a diagnosis for the previous violation cause contains two records (timestamps and signal values) where the signal shows its minimum and maximum values, while increasing. These values allow engineers to understand the range of values taken by the signal while it exhibits an increasing behavior.

We propose a novel *methodology to define violation causes and diagnoses* (Section 5). Our methodology provides formal guarantees of the soundness of the proposed violation causes: if a violation cause holds on a trace, the corresponding property is violated. Though we applied our methodology to define violation causes for properties expressed using SB-TemPsy-DSL, our methodology is language-agnostic and can therefore be applied to other pattern-based specification languages such as TemPsy [17] and FRETISH [18].

We present a *catalog of 34 violation causes, each associated with one diagnosis*, for signal-based temporal properties expressed in SB-TemPsy-DSL (Section 6). These violation causes are not complete as they do not encode all the

possible reasons that may lead to a property violation, but are the results of applying our methodology in the context of our industrial case study. However, following the same methodology, users can add new violation causes depending on their specific needs or on the requirements of particular domains.

We implemented *TD-SB-TemPsy* as a plugin for SB-TemPsy-Check [1], a trace-checking tool for SB-TemPsy-DSL. We assessed the applicability of *TD-SB-TemPsy* on a large industrial dataset. *TD-SB-TemPsy* could finish within a timeout of 1 min for  $\approx 83.66\%$  of the trace-property combinations in our dataset, yielding a diagnosis in  $\approx 99.84\%$  of these cases.

*Significance.* Since diagnoses were provided in  $\approx 99.84\%$  of the cases for which no timeout occurred, *TD-SB-TemPsy* was widely applicable across trace-property combinations in our dataset. Given the high expressiveness of SB-TemPsy-DSL, the many violation causes and related diagnoses we have defined in *TD-SB-TemPsy*, and the run-time performance of our tool, we expect significant impact for this technology across many CPS domains. Moreover, the methodology for defining violation causes and diagnoses can be adopted by other researchers working on the problem of trace diagnostics in the context of run-time verification.

To summarize, the main contributions of this paper are:

- *TD-SB-TemPsy*, a trace-diagnostic approach for signal-based temporal properties expressed in SB-TemPsy-DSL, based on the concepts of *violation cause* and *diagnosis*;
- a language-agnostic methodology for defining violation causes and diagnoses, with formal guarantees of the soundness of the proposed violation causes, and its application to SB-TemPsy-DSL;
- a catalog of 34 violation causes, each associated with one diagnosis, for signal-based temporal properties expressed in SB-TemPsy-DSL;
- a comprehensive evaluation of the applicability of *TD-SB-TemPsy* on an industrial case study.

*Paper structure.* This paper is organized as follows. Section 2 introduces our case study from the satellite domain and identify concrete motivations for our work. Section 3 illustrates the syntax and semantics of SB-TemPsy-DSL. Section 4 presents *TD-SB-TemPsy*, our pattern-based trace-diagnostic approach. Section 5 describes our methodology to define violation causes and diagnoses. Section 6 presents the violation causes and diagnoses proposed in this work. Section 8 evaluates our solution on an industrial case study. Section 9 discusses related work. Section 10 concludes the paper, providing directions for future work.

## 2 CASE STUDY AND MOTIVATIONS

Our case study is a satellite developed by our industrial partner. This is a representative CPS as it contains many complex software components that interact with actuators and sensors of the satellite.

During the satellite development, and after its deployment, engineers collect traces that describe the behavior of the satellite. A fragment of one of these traces is depicted in Figure 1 and plotted in Figure 2. A trace is a sequence of records that describe how the values of some signals change

$\beta$	2.0	153.5	55.0	0.5	80.0	203.5	20.0	0.5
$\rho$	1.0	52.5	125.0	125.5	25.0	75.5	35.0	200.5
timestamp	0.0	0.2	0.9	1.8	3.0	4.9	5.7	6.0

Record  $r_3$

Figure 1. A fragment of a trace from our case study.

Figure 2. Graphical representation of the trace in Figure 1.

over time. For example, the fragment of the trace in Figure 1 contains eight records. Each record contains a timestamp, identifying the time at which the record was collected, and the values assumed by some variables, each recording the values of one of the monitored signals at that time. In the example, the variables  $\beta$  and  $\rho$  record respectively the signals representing the beta angle [19] and the pointing error [20] of the satellite. For example, for record  $r_3$  the timestamp is 0.9, and the values of the variables  $\beta$  and  $\rho$  are respectively  $55.0^\circ$  and  $125.0^\circ$ . The recording interval of a trace is the difference between the maximum and the minimum timestamps. For example, the recording interval of the trace in Figure 1 is 6 s.

After the traces are collected, engineers analyze whether the behaviors recorded in the traces satisfy the CPS requirements. An example of a requirement (inspired by the ones from the case study) is the following:

R1: “Within the trace, the beta angle shall contain at least one spike with an amplitude lower than  $90^\circ$  and a width less than 0.5 s”.

The beta angle is the angle between the orbital plane of the satellite and the vector of the Sun (i.e., the direction from which the Sun is shining). After deployment, the satellite aligns its orbital plane. Therefore,  $\beta$  shall contain a spike with an amplitude lower than  $90^\circ$ . The trace shown in Figure 1 violates the requirement R1. As we will discuss in the next section, automated trace-checking tools, such as SB-TemPsy-Check [1] (see section 3), can verify whether a trace satisfies or violates a requirement. However, they do not provide any additional information to help engineers understand the cause of the violation. This means that engineers have to manually inspect the values of the variables recorded in the trace records and check why these values led to the violation of the requirement. In our example, looking at the plot in Figure 2, one can see that the two

<b>Property</b>	$\phi ::= \phi_1 \text{ or } \phi_2 \mid \delta$
<b>Clause</b>	$\delta ::= \delta_1 \text{ and } \delta_2 \mid \alpha$
<b>Atom</b>	$\alpha ::= \text{not } \text{sc} \mid \text{sc}$
<b>Scope</b>	$\text{sc} ::= \text{globally } p \mid \text{before } t p \mid \text{after } t p \mid \text{at } t p \mid \text{before } p_1 p \mid \text{after } p_1 p \mid \text{between } t_1 \text{ and } t_2 p \mid \text{between } p_1 \text{ and } p_2 p$
<b>Pattern</b>	$p ::= \text{assert } c \mid \text{s becomes } \sim v \mid \text{if } p_1 \text{ then } [\text{within } \bowtie t] p_2 \mid \text{exists spike in s } [\text{with } [\text{width } \sim_1 v_1] \mid [\text{amplitude } \sim_2 v_2]] \mid \text{exist oscillation in s } [\text{with } [\text{p2pAmp } \sim_1 v_1] \mid [\text{period } \sim_2 v_2]] \mid \text{s rises } [\text{monotonically}] \text{ reaching } v \mid \text{s falls } [\text{monotonically}] \text{ reaching } v \mid \text{s overshoots } [\text{monotonically}] v_1 \text{ by } v_2 \mid \text{s undershoots } [\text{monotonically}] v_1 \text{ by } v_2$ $\bowtie ::= \text{exactly} \mid \text{at most} \mid \text{at least}$
<b>Condition</b>	$c ::= c_1 \text{ and } c_2 \mid c_1 \text{ or } c_2 \mid s \sim v$

$t, t_1, t_2 \in \mathbb{R}; v, v_1, v_2 \in \mathbb{R}; \sim \in \{<, >, =, <>, <=, >=\};$   
 $s$  is a signal or a mathematical expression over the signals.

Figure 3. SB-TemPsy-DSL syntax.

spikes (i.e., *spike1* and *spike2* defined over the time intervals  $[0, 1.8]$  and  $[1.8, 6.0]$ ) of signal  $\beta$  have an amplitude value ( $A_1 = 153.5^\circ$  and  $A_2 = 203.5^\circ$ ) greater than  $90^\circ$  and show a width ( $w_1 = 1.8$  s and  $w_2 = 4.2$  s) greater than 0.5 s. Our pattern-based diagnostic approach (see section 4) aims to automatically detect the causes of requirement violation.

### 3 BACKGROUND: SB-TEMPSY-DSL

SB-TemPsy-DSL [1] is a domain-specific language for expressing requirements that concern signal-based temporal properties. The syntax of SB-TemPsy-DSL is shown in Figure 3; optional items are enclosed in square brackets; the symbol ‘|’ separates alternatives.<sup>1</sup> A *property* is a disjunction of clauses. A *clause* is a conjunction of atoms. An *atom* is defined in terms of a *scope* (non-terminal *sc*) or the negation operator (**not**) applied to constructs of type *scope* (*sc*). A *scope* operator constrains a *pattern* (non-terminal *p*) to hold within a given time interval. There are two types of *scope* operators: absolute scopes and event scopes. Absolute scopes are delimited by absolute time instants (e.g., **before**  $t$   $p$ ). Event scopes are delimited by other patterns (e.g., **before**  $p_1$   $p$ ). A *pattern* (e.g., **exists spike in**  $s$  [...]) specifies a constraint on the behavior of one or more signals. A *condition*, which is used within the **assert**  $c$  pattern, is a comparison ( $s \sim v$ ) between the value of a signal  $s$  and the value  $v$ , or a combination of two conditions with the **and** and **or** logical operators.

The syntax of SB-TemPsy-DSL enables engineers to define the property  $\phi_1$  expressing requirement R1 (see Section 2) as:  $\phi_1 \equiv \text{globally exists spike in } \beta \text{ with width } < 0.5 \text{ amplitude } < 90$ . Note that this property is made by a single atom (represented by the **globally** scope construct).

1. The grammar of SB-TemPsy-DSL considered in this paper is slightly different from the original one [1]. Any SB-TemPsy-DSL property can be rewritten following this grammar by using standard rewriting rules [21].

$\lambda \models \phi_1 \text{ or } \phi_2 \text{ iff } (\lambda \models \phi_1) \vee (\lambda \models \phi_2);$	$\lambda \models \delta_1 \text{ and } \delta_2 \text{ iff } (\lambda \models \delta_1) \wedge (\lambda \models \delta_2);$	$\lambda \models \text{not sc iff } (\lambda \not\models \text{sc})$
$\lambda \models \text{before } t \text{ p iff } t_i < t \leq t_e \wedge \lambda, [t_i, t] \models \text{p};$	$\lambda \models \text{between } n \text{ and } m \text{ p iff } t_i \leq n < m \leq t_e \wedge \lambda, [n, m] \models \text{p}$	
$\lambda \models \text{globally } \text{p iff } \lambda, [t_i, t_e] \models \text{p};$	$\lambda \models \text{at } t \text{ p iff } t_i \leq t \leq t_e \wedge \lambda, [t, t] \models \text{p};$	$\lambda \models \text{after } t \text{ p iff } t_i \leq t < t_e \wedge \lambda, [t, t_e] \models \text{p}$
$\lambda \models \text{before } \text{p}_1 \text{ p iff } \forall t_1, t_2, ((t_i < t_1 < t_2 \leq t_e \wedge \lambda, [t_1, t_2] \models \text{p}_1) \Rightarrow \exists t_3, t_4, (t_i \leq t_3 < t_4 < t_1 \wedge \lambda, [t_3, t_4] \models \text{p}))$		
$\lambda \models \text{after } \text{p}_1 \text{ p iff } \forall t_1, t_2, ((t_i \leq t_1 < t_2 < t_e \wedge \lambda, [t_1, t_2] \models \text{p}_1) \Rightarrow \exists t_3, t_4, (t_2 < t_3 < t_4 \leq t_e \wedge \lambda, [t_3, t_4] \models \text{p}))$		
$\lambda \models \text{between } \text{p}_1 \text{ and } \text{p}_2 \text{ p iff } \forall t_1, t_2, t_3, t_4, ((t_i \leq t_1 < t_2 < t_3 < t_4 \leq t_e \wedge \lambda, [t_1, t_2] \models \text{p}_1 \wedge \lambda, [t_3, t_4] \models \text{p}_2) \Rightarrow \lambda, [t_2, t_3] \models \text{p})$		
$\lambda, [t_l, t_u] \models \text{assert } \text{c iff } \forall t \in [t_l, t_u], (\lambda, t \models \text{c}).$ For every time instant $t$ within $[t_l, t_u]$ , condition $\text{c}$ holds.		
$\lambda, [t_l, t_u] \models \text{s becomes } \sim v \text{ iff } \exists t \in (t_l, t_u), (\text{s}(t) \sim v \wedge \forall t_1 \in [t_l, t), (\text{s}(t_1) \not\sim v)).$ Formula $\text{s}(t) \sim v$ is true for some $t$ , and for any time instant $t_1$ before $t$ , $\text{s}(t_1) \not\sim v$ is false.		
$\lambda, [t_l, t_u] \models \text{exists spike in s [with [width } \sim_1 v_1 \text{] [amplitude } \sim_2 v_2 \text{]}_\alpha \text{ iff } \exists t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], (t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_m\_max}(s, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_min}(s, t_3, [t_2, t_4]) \wedge \text{uni\_m\_max}(s, t_4, [t_3, t_5])) [(\wedge (t_3 - t_1) \sim_1 v_1)_\beta \wedge \text{max}((\text{s}(t_2) - \text{s}(t_3)), (\text{s}(t_4) - \text{s}(t_5))) \sim_2 v_2)_\gamma]_\alpha.$ Signal $\text{s}$ has a strict maximum within two (non strict) minima. The values $v_1$ and $v_2$ constrain the width and the amplitude of the spike.*		
$\lambda, [t_l, t_u] \models \text{exist oscillation in s [with [period } \sim_1 v_1 \text{] [p2pAmp } \sim_2 v_2 \text{]}_\epsilon \text{ iff } \exists t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], (t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_max}(s, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_min}(s, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_max}(s, t_4, [t_3, t_5])) [(\wedge (t_4 - t_2) \sim_1 v_1)_\zeta \wedge (\text{s}(t_2) - \text{s}(t_3)) \sim_2 v_2 \wedge (\text{s}(t_4) - \text{s}(t_5)) \sim_2 v_2]_\epsilon]_\delta.$ Signal $\text{s}$ shows a strict maximum within two strict minima. The values $v_1$ and $v_2$ constrain the period and the amplitude of the oscillation.*		
$\lambda, [t_l, t_u] \models \text{s rises [monotonically]}_\alpha \text{ reaching } v \text{ iff } \exists t \in (t_l, t_u), (\text{s}(t) \geq v \wedge \forall t_1 \in [t_l, t), (\text{s}(t_1) < v) \wedge \text{monot}(\text{s}, t_1, t))_\alpha.$ There exists a time instant $t$ where $\text{s}(t) \geq v$ , and for any time instant $t_1$ before $t$ , $\text{s}(t_1) < v$ . The character $\alpha$ labels the formula indicating that the signal shall rise monotonically.		
$\lambda, [t_l, t_u] \models \text{s overshoots [monotonically]}_\alpha v_1 \text{ by } v_2 \text{ iff } \exists t \in (t_l, t_u), (\text{s}(t) \geq v_1 \wedge \forall t_1 \in [t_l, t), (\text{s}(t_1) \leq v_1 + v_2) \wedge \forall t_2 \in [t_l, t) (\text{s}(t_2) < v_1) \wedge \text{monot}(\text{s}, t_1, t))_\alpha.$ Signal $\text{s}$ is initially lower than $v_1$ . It then exceeds $v_1$ at time instant $t$ by remaining below $v_1 + v_2$ . The character $\alpha$ labels the formula indicating that the signal shall overshoot monotonically.		
$\lambda, [t_l, t_u] \models \text{if } \text{p}_1 \text{ then [within } \bowtie d \text{]}_\alpha \text{ p}_2 \text{ iff } \forall t_1, t_2 \in [t_l, t_u], ((t_1 < t_2 \wedge \lambda, [t_1, t_2] \models \text{p}_1) \Rightarrow \exists t_3, t_4 \in [t_2, t_u], (t_3 < t_4 \wedge \lambda, [t_3, t_4] \models \text{p}_2 \wedge (t_3 - t_2) \bowtie d)_\alpha)$ where $\bowtie$ is such that $\llbracket \text{exactly} \rrbracket \equiv '='$ , $\llbracket \text{at most} \rrbracket \equiv '<='$ , $\llbracket \text{at least} \rrbracket \equiv '>='$ . If pattern $\text{p}_1$ holds in an interval $[t_1, t_2]$ , then pattern $\text{p}_2$ holds in a subsequent interval $[t_3, t_4]$ .		
$\lambda, t \models \text{c}_1 \text{ and } \text{c}_2 \text{ iff } (\lambda, t \models \text{c}_1) \wedge (\lambda, t \models \text{c}_2);$	$\lambda, t \models \text{c}_1 \text{ or } \text{c}_2 \text{ iff } (\lambda, t \models \text{c}_1) \vee (\lambda, t \models \text{c}_2);$	$\lambda, t \models \text{s} \sim v \text{ iff } \text{s}(t) \sim v$

$t, t_1, t_2 \in \mathbb{R}; v, v_1, v_2 \in \mathbb{R}; \sim \in \{<, >, \neq, \leq, \geq\}; \text{s}$  is a signal in  $S$  or a mathematical expression over the signals in  $S$ .

$\text{monot}(\text{s}, t_1, t_2) ::= \forall t_3 \in [t_1, t_2], \forall t_4 \in (t_3, 2], (\text{s}(t_3) < \text{s}(t_4)).$

$\text{uni\_m\_max}(\text{s}, t, [t_a, t_b]) ::= \text{s}(t) = x \text{ and } \forall t_1 \in [t_a, t_b], \text{s}(t_1) < x \text{ and } \forall t_1, t_2 \in [t_a, t], \text{ if } t_1 < t_2 \text{ then } \text{s}(t_1) \leq \text{s}(t_2) \text{ and } \forall t_1, t_2 \in [t_a, t], \text{ if } t_1 < t_2 \text{ then } \text{s}(t_1) \geq \text{s}(t_2)$

$\text{uni\_sm\_max}(\text{s}, t, [t_a, t_b]) ::= \text{s}(t) = x \text{ and } \forall t_1 \in [t_a, t_b], \text{s}(t_1) < x \text{ and } \forall t_1, t_2 \in [t_a, t], \text{ if } t_1 < t_2 \text{ then } \text{s}(t_1) < \text{s}(t_2) \text{ and } \forall t_1, t_2 \in [t_a, t], \text{ if } t_1 < t_2 \text{ then } \text{s}(t_1) > \text{s}(t_2)$

\* We present the case where a (strict) minimum is followed by a strict maximum followed by a (strict) minimum. The dual case can be derived from our formulation. Similarly, we present the predicates that characterize a local (strict) maximum ( $\text{uni\_m\_max}$  and  $\text{uni\_sm\_max}$ ). Their dual case, i.e., the predicates that characterize a local (strict) minimum ( $\text{uni\_m\_min}$  and  $\text{uni\_sm\_min}$ ) can be derived from the above formulations.

Figure 4. SB-TemPsy-DSL formal semantics (based on [1])

The semantics of each construct  $\eta$  of SB-TemPsy-DSL is shown in Figure 4, which is divided into four parts. The first part contains the semantics of properties, clauses, and atoms. The other three parts address the semantics of scopes, patterns, and conditions. The semantics of a construct  $\eta$  is the formula  $\zeta(\eta)$  (in first-order logic) written on the right side of the *iff* (if and only if) sign. For properties, the semantics specifies the conditions that make a property  $\phi$  satisfied by the trace  $\lambda$ , i.e.,  $\lambda \models \phi$ . For example, the semantics of  $\phi_1 \text{ or } \phi_2$  requires at least one of them to hold on trace  $\lambda$ . For scopes, the semantics specifies the conditions that make a scope  $\text{sc}$  satisfied on the trace  $\lambda$ , i.e.,  $\lambda \models \text{sc}$ . For example, the semantics of the **globally** scope indicates that a pattern  $\text{p}$  scoped by the **globally** operator holds on the trace  $\lambda$  if the pattern  $\text{p}$  holds on the interval of the trace  $\lambda$  delimited by the timestamps  $t_i$  and  $t_e$ . The timestamps  $t_i$  and  $t_e$  indicate the initial and the last timestamps of the trace. For patterns, the semantics specifies the conditions that make a pattern  $\text{p}$  satisfied on the interval of the trace  $\lambda$  delimited by the timestamps  $t_l$  and  $t_u$  defined by a given scope, i.e.,  $\lambda, [t_l, t_u] \models \text{p}$ . Figure 4 also includes an informal description of the pattern semantics, after the formal definition. For example, the semantics of pattern “**exists spike in s with width**  $\sim_1 v_1$  **amplitude**  $\sim_2 v_2$ ” specifies that signal  $\text{s}$  shows a spike behavior with a width satisfying the constraint “ $\sim_1 v_1$ ” and an ampli-

tude satisfying the constraint “ $\sim_2 v_2$ ”. A spike informally denotes a temporary (large) increase (or decrease) of the value of a signal. It occurs when the signal has a strict maximum surrounded by two minima (or a strict minimum surrounded by two maxima). This behavior can be subjected to additional constraints on the width (i.e., the difference between the time instants at which the two minima — or the two maxima occur) and on the amplitude (i.e., the difference between the maximum and minimum values of the signal). Finally, the semantics of conditions specifies how to satisfy a condition  $\text{c}$  for a trace  $\lambda$  at time instant  $t$ , i.e.,  $\lambda, t \models \text{c}$ . For example, the semantics of  $\text{c}_1 \text{ and } \text{c}_2$  requires both  $\text{c}_1$  and  $\text{c}_2$  to hold on the trace  $\lambda$  at timestamp  $t$ .

SB-TemPsy-DSL is supported by SB-TemPsy-Check [1], an automated, model-driven trace-checking tool that verifies whether a property is satisfied or violated by a given trace. SB-TemPsy-Check yields a Boolean verdict: *true* if the property is satisfied, *false* otherwise. For example, when property  $\phi_1$  is checked on the trace shown in Figure 1, SB-TemPsy-Check returns the *false* verdict. However, SB-TemPsy-Check does not provide any additional information to help engineers understand the cause of the violation. Our trace diagnostic approach aims to solve this problem.

**Algorithm 1** *TD-SB-TemPsy*

**Inputs.**  $\lambda$ : trace  
 $\phi$ : violated property  
**Outputs.** *diags*: set of diagnoses instances

```

1: function TD-SB-TEMPsy( $\lambda, \phi$ )
2:   diags={};
3:   PropertyAtoms=GETATOMS( $\phi$ );
4:   for  $\alpha$  in PropertyAtoms do
5:     if CHECKATOMONTRACE( $\lambda, \alpha$ )==false then
6:       diags.add(TD-ATOM( $\lambda, \alpha$ ))
7:   return diags;

```

**4** PATTERN-BASED TRACE DIAGNOSTIC

This section describes *TD-SB-TemPsy*, our trace-diagnostic approach. At the core of the approach, there is the computation of *violation causes* and *diagnoses*. A violation cause characterizes one of the possible behaviors of the system that may lead to the property violation. An example of violation cause for property  $\phi_1$  and the trace in Figure 2 is that all the spikes have an amplitude greater than or equal to  $90^\circ$ . A diagnosis provides additional information to explain the violation cause. For example, a diagnosis for the previous violation cause is the amplitude  $A_1 = 150^\circ$  and the time interval  $[0\text{s}, 1.8\text{s}]$  of spike *spike1*, that is the closest (among those contained in the trace) to satisfy the amplitude constraint of property  $\phi_1$ .

Algorithm 1 shows the main steps of *TD-SB-TemPsy*. The inputs of *TD-SB-TemPsy* are a trace  $\lambda$  and a property  $\phi$  violated by  $\lambda$ . Trace  $\lambda$  is a set of consecutive records that contain the values of the variables at different time instants, such as the trace depicted in Figure 1. Property  $\phi$  is a specification of a requirement in SB-TemPsy-DSL defined according to the grammar presented in Figure 3.

The algorithm relies on the following intuition. Based on the SB-TemPsy-DSL grammar shown in Figure 3, property  $\phi$  is specified as a disjunction of clauses. Since the property is violated, the disjunction evaluates to false; this means that all its clauses must be violated. To be violated, each clause must contain one or more violated atoms (since a clause is a conjunction of atoms). Therefore, to explain the violation of property  $\phi$ , we return the diagnoses (if available<sup>2</sup>) for all the violated atoms of  $\phi$ . Each diagnosis explains why the corresponding atom is violated.

Algorithm 1 works as follows. After initializing a set of diagnoses instances to be returned (line 2), it extracts all the atoms from property  $\phi$  by analyzing its abstract syntax tree (line 3). Then, it iteratively analyzes each atom (line 4). It first checks, by calling a trace checker for SB-TemPsy-DSL like SB-TemPsy-Check [1], if the atom is violated by the trace (line 5). If it is the case, the algorithm computes (through algorithm TD-ATOM described below) the diagnosis (if available) that explains why the atom is violated (line 6). Finally, the algorithm returns the set of the computed diagnoses instances (line 7). *TD-SB-TemPsy* returns a diagnosis if the set of the computed diagnoses instances is not empty.

*Computing the diagnosis.* Algorithm 2 describes how to compute the diagnosis for an atom of an SB-TemPsy-DSL

2. As we will discuss later on, it is possible for a violated atom not to have any diagnosis.

**Algorithm 2** *TD-SB-TemPsy - Atoms*

**Inputs.**  $\lambda$ : trace  
 $\alpha$ : violated atom  
**Outputs.** *diag*: diagnosis for  $\alpha$  (if available)

```

1: function TD-ATOM( $\lambda, \alpha$ )
2:   vcs=GETVIOLATIONCAUSES( $\alpha$ );
3:   for  $i=0$ ;  $i <$  vcs.size();  $i++$  do
4:     if CHECKVIOLATIONCAUSE( $\lambda, \text{vcs}[i]$ )==true then
5:       return GETDIAGNOSIS( $\lambda, \text{vcs}[i]$ );
6:   return null;

```

property. The inputs of TD-ATOM are a trace  $\lambda$  and an atom  $\alpha$  violated by  $\lambda$ .

To compute the diagnosis for atom  $\alpha$ , Algorithm 2 extracts the *violation causes* associated with the atom (line 2) by calling the auxiliary function GETVIOLATIONCAUSES, which relies on a predefined mapping associating each type of atom of SB-TemPsy-DSL with one or more violation causes (see section 6). A violation cause encodes a behavior that may lead to the violation of an atom. For example, a violation cause for the atom of property  $\phi_1$  defined in Section 2 is the following:

**c\_spike<sub>1</sub>**: all the spikes in signal  $\beta$  violate the amplitude constraint.

If the behavior captured by this violation cause holds, the atom of formula  $\phi_1$  is violated. The violation of an atom can be caused by a violation of the scope used in the atom (or its negation), a violation of the pattern constrained by the scope, or both. Function GETVIOLATIONCAUSES returns a list of violation causes, sorted such that violation causes of the scope precede the violation causes of the pattern<sup>3</sup>. Then, the algorithm loops through this list of violation causes (line 3). The loop body includes a check that determines whether the violation cause holds on the trace (line 4); this is achieved through the call of the auxiliary function CHECKVIOLATIONCAUSE. If the violation cause holds, the algorithm stops, returning the corresponding diagnosis (line 5) using the auxiliary function GETDIAGNOSIS, which relies on a predefined mapping of diagnoses for each type of violation cause (see section 6). A diagnosis is relevant information that enables engineers to understand *why a violation cause holds on a trace*. For example, the diagnosis for the violation cause **c\_spike<sub>1</sub>** is the following

**d\_spike<sub>1</sub>**: the amplitude  $a$  and the time interval  $[t_1, t_2]$  of the spike that is the closest to satisfy the amplitude constraint.

The amplitude value of the spike that is the closest to satisfy the amplitude constraint enables engineers to determine how close is the atom to be satisfied. The time interval  $[t_1, t_2]$  enables engineers to isolate the portion of the trace containing that spike and to inspect the values assumed by the variables within the records included in this portion of the trace. The amplitude  $A_1 = 150^\circ$  and the time interval  $[0, 1.8]$  of *spike1* in Figure 2 is an instance of the **d\_spike<sub>1</sub>** diagnosis for our case study. Diagnoses like **d\_spike<sub>1</sub>** help engineers understand why an atom is violated by a trace. If all the violation causes are checked and none of them led

3. The priority of the different violation causes is application-specific. Our current implementation is based on the feedback received by the engineers of our industrial partners

to the computation of diagnoses, a null value is returned (line 6).

In the following, we present our methodology to define violation causes and diagnoses.

## 5 METHODOLOGY FOR DEFINING VIOLATION CAUSES AND DIAGNOSES

This section describes our methodology to define violation causes and diagnoses by using SB-TemPsy-DSL as an example. Our methodology considers each construct  $\eta$  used to define an atom  $\alpha$  of SB-TemPsy-DSL and follows three steps: *behavior analysis*, *definition of violation causes*, and *definition of diagnoses*.

### Behavior Analysis.

It identifies traces capturing relevant behaviors that violate the semantics of construct  $\eta$  as follows.

- 1) It considers an instance of construct  $\eta$  obtained by selecting some values for its parameters. This instance is a concrete example used to identifying the relevant behaviors that violate  $\eta$ . For example, for the **spike** construct of SB-TemPsy-DSL (see Figure 3), we considered the instance “exists spike in  $\beta$  with width  $< 0.5$  amplitude  $< 90$ ”, which sets the parameters  $s$ ,  $\sim_1$ ,  $v_1$ ,  $\sim_2$ , and  $v_2$  to the values  $\beta$ , “ $<$ ”,  $0.5$ , “ $<$ ”, and  $90$  respectively.
- 2) It considers the logical formula  $\zeta(\eta)$  describing the semantics of the construct  $\eta$ . For example, for the **spike** construct the logical formula describing its semantics is reported in Figure 4 (on the right side of the *iff* operator).
- 3) It identifies traces capturing relevant behaviors that violate the instance of construct  $\eta$  (i.e., that make formula  $\zeta(\eta)$  evaluate to *false*).

For example, Figure 5 shows a trace with four signals ( $\beta_1$ ,  $\beta_2$ ,  $\beta_3$ , and  $\beta_4$ ) that violate the instance we considered for the **spike** construct; for instance, signal  $\beta_4$  does not contain a strict maximum.

Figure 5. A trace with signals violating the expression “exists spike in  $\beta$  with width  $< 0.5$  amplitude  $< 90$ ”.

### Definition of Violation Causes.

It characterizes each of the traces identified by the behavior analysis step through a violation cause. Each violation cause

$vc$  is defined by writing a logical formula  $\zeta(vc)$  that specifies its semantics; the formula  $\zeta(vc)$  is true when trace  $\lambda$  satisfies violation cause  $vc$ .

For example, the shape of signal  $\beta_3$  can be defined, with respect to a trace  $\lambda$  delimited by timestamps  $t_i$  and  $t_e$ , through the logical formula:

$$\mathbf{c\_spike}_4 \equiv \forall t_1 \in [t_l, t_u), (\forall t_2 \in (t_1, t_u], (s(t_1) \geq s(t_2))).$$

This formula characterizes the behavior for which a signal  $s$  decreases. More precisely,  $\mathbf{c\_spike}_4$  holds on a trace  $\lambda$  if, for any timestamp  $t_1$  within  $t_l$  and  $t_u$ , the value  $s(t_1)$  of signal  $s$  at timestamp  $t_1$  is greater than or equal to the value  $s(t_2)$  of signal  $s$  for any timestamp  $t_2$  that follows  $t_1$ .

Violation causes for SB-TemPsy-DSL are illustrated in section 6 (and summarized in Figure 6). The formula  $\zeta(vc)$  characterizing the semantics of each violation cause is reported on the right side of the *iff* operator.

Since violation causes should encode root causes leading to property violations, a violation cause  $vc$  for a construct  $\eta$  should satisfy the following relation:

$$\text{if } \zeta(vc) = \text{true}, \text{ then } \zeta(\eta) = \text{false}$$

Intuitively, if violation cause  $vc$  holds on trace  $\lambda$ , i.e., formula  $\zeta(vc)$  is true, the trace  $\lambda$  should violate construct  $\eta$ , i.e., formula  $\zeta(\eta)$  should be false. To check the satisfaction of this relation, we automatically verified that the formula

$$\Psi \equiv \zeta(vc) \Rightarrow \neg \zeta(\eta)$$

holds. Formula  $\Psi$  holds if, whenever the violation cause holds ( $\zeta(vc)$  is true), the construct  $\eta$  does not hold ( $\zeta(\eta)$  is false). To check if formula  $\Psi$  holds, we verified whether the formula  $\neg \Psi$  is unsatisfiable. If the formula  $\neg \Psi$  is unsatisfiable,  $\Psi$  always holds. We used Microsoft Z3 [22] — an industry-strength tool — to check if  $\neg \Psi$  is unsatisfiable. For example, Z3 confirmed that the formula  $\neg \Psi$  obtained by considering the  $\mathbf{c\_spike}_4$  violation cause and the **spike** construct is unsatisfiable. Therefore, whenever violation cause  $\mathbf{c\_spike}_4$  holds, the **spike** construct is violated.

### Definition of diagnoses.

It defines a diagnosis for each of the violation causes. To define each diagnosis, we (i) analyzed the semantics of the corresponding violation cause, and (ii) identified minimum relevant information that enables engineers to understand why a violation cause holds on a trace.

For example, the diagnosis for violation cause  $\mathbf{c\_spike}_4$ , denoted by  $\mathbf{d\_spike}_4$ , includes the lowest and the highest values of signal  $s$  within the trace. These values allow engineers to understand the range of values of signal  $s$  while it exhibits a decreasing behavior. For example, for signal  $\beta_3$  in Figure 5, the diagnosis for violation cause  $\mathbf{c\_spike}_4$  is  $\langle\langle 0, 200 \rangle, \langle 6, 55 \rangle\rangle$  showing that signal  $\beta_3$  reaches its maximum value (200) at timestamp 0 and its minimum value (55) at timestamp 6. In this particular case, when the signal does not show any spike, this is the only information required for the engineers to understand why this particular violation was caused.

The diagnoses associated with the violation causes shown in Figure 6 are illustrated in section 6 (and summarized in Figures 7–8).

## Properties of the methodology.

Our methodology provides formal guarantees of the soundness of the proposed violation causes: if a violation cause holds on a trace, the corresponding property is violated.

Though we applied our methodology to define violation causes for properties expressed using SB-TemPsy-DSL, our methodology is *language-agnostic*. More specifically, this claim is supported by the fact that, in the definition of the methodology, we only refer to generic syntactic constructs of the specification language and generic logical formulae capturing their semantics (which we assume to be available in formal syntax and semantics definitions), as well as generic logical formulae of violation causes (which have to be defined from scratch). Examples of pattern-based languages for which this methodology can be applied (i.e., for which assumptions are satisfied) are TemPsy [17], FRETISH [18] and, more in general, languages based on specification pattern catalogues (such as those for robotic missions [7]).

## 6 VIOLATION CAUSES AND DIAGNOSES FOR SB-TEMPSY-DSL

In this section, we describe the *violation causes* and the corresponding *diagnoses* for each *construct* supported by SB-TemPsy-DSL. We first provide a high-level overview through Figure 6 (for *violation causes*) and Figures 7–8 (for *diagnoses*); the remaining subsections discuss in detail the violation causes and diagnoses for each main construct of SB-TemPsy-DSL.

Figure 6 presents the *violation causes* for the constructs of SB-TemPsy-DSL that can be used in the definition of an *atom*  $\alpha$ . It is divided into three parts that respectively contain the violation causes for the SB-TemPsy-DSL atoms, scopes, and patterns. Each violation cause has a name that identifies the construct of SB-TemPsy-DSL the violation cause refers to, and an incremental index that distinguishes violation causes that refer to the same construct; for example,  $c\_becomes_1$ ,  $c\_becomes_2$ , and  $c\_becomes_3$  are the three violation causes that refer to the **becomes** construct of SB-TemPsy-DSL. Each violation cause is parameterized with the *same* parameters as the corresponding construct. For example, the parameters of the  $c\_becomes_1$  violation cause ( $\sim$  and  $v$ ) are the same as those of the **becomes** construct in Figure 3. For conciseness, in Figure 6, we omit the parameters of the violation causes.

The semantics of each violation cause is the (first-order logic) formula  $\zeta(vc)$  on the right side of the *iff* operator; it is followed by an informal description of the semantics in English. The semantics of the violation causes specifies the conditions that make the violation causes satisfied by trace  $\lambda$ . For example, the semantics of the violation cause  $c\_becomes_1$  specifies that, for every timestamp  $t$ , the value  $s(t)$  does not satisfy  $s(t) \sim v$ . Note that the parameters of the SB-TemPsy-DSL constructs associated with the violation causes, e.g., the value of  $v$ , are used to define the semantics of the corresponding violation cause.

Figures 7–8 present the *diagnoses* for the *violation causes* in Figure 6. Figure 7 contains the diagnoses related to the violation causes for SB-TemPsy-DSL atoms and scopes,

while Figure 8 contains the diagnoses related to violation causes for patterns.

The name of the diagnosis is obtained by replacing the string “ $c\_$ ” with “ $d\_$ ” from the name of the corresponding violation cause. For example, diagnosis  $d\_becomes_1$  refers to violation cause  $c\_becomes_1$ .

The formal definition of the diagnosis is reported on the right side of the symbol “ $=$ ”. For example, the definition of the diagnosis  $d\_becomes_1$  is the tuple containing the maximum and the minimum values (as well as their timestamps) of signal<sup>4</sup>  $s$ . Violation causes sharing the same diagnosis are separated by the symbol “ $/$ ”. For example,  $d\_a\_at_1/d\_a\_bef_1/d\_a\_aft_1$  is the diagnosis associated with violation causes  $c\_a\_at_1$ ,  $c\_a\_bef_1$ , and  $c\_a\_aft_1$ . The *informal definition* provides a high-level description of the diagnosis.

### 6.1 Patterns

#### 6.1.1 **assert**: Event-based Data Assertion

**Violation cause:** This pattern is violated if there exists at least one record in the trace that violates the condition used in the assertion. Recall that a record is used to represent a timestamp and a signal value observed in that timestamp. Therefore, the corresponding violation cause  $c\_assert_1$  checks for the presence of a timestamp in which the assertion condition  $c$  is violated.

For example, the trace shown in Figure 9 violates the expression “**assert**  $\beta_1 < 4$ ” because signal  $\beta_1$  shows a value equal to 5 at timestamp 4, satisfying the violation cause  $c\_assert_1$  on the interval  $[0, 7]$ .

**Diagnoses:** The diagnosis  $d\_assert_1$  associated with violation cause  $c\_assert_1$  includes the first timestamp  $t$  at which one or more signals ( $s_1, s_2, \dots, s_n$ ) violate the assertion condition  $c$ , as well as the values taken by these signals at  $t$ . This diagnosis allows engineers to identify the root cause of the violation of the assertion condition by looking at the first timestamp in which this violation was observed.

For instance, in the case of the trace shown in Figure 9, the diagnosis is the tuple containing timestamp 4 and the value of  $\beta_1(4) = 5$  taken by signal  $\beta_1$ .

#### 6.1.2 **becomes**: State-based Data Assertion

**Violation causes:** This pattern can be violated in at least three ways, as illustrated with different signal behaviors in Figure 10 using the expression “ $\beta$  **becomes**  $> 3$ ”:

- $c\_becomes_1$ : The signal value violates the pattern constraint  $\sim v$  throughout the time interval over which the pattern is evaluated. For instance, signal  $\beta_1$  in the figure is never greater than 3.
- $c\_becomes_2$ : The signal value satisfies the pattern constraint  $\sim v$  throughout the time interval over which the pattern is evaluated. This violation cause is the dual of the previous case. For instance, signal  $\beta_2$  in the figure is always greater than value 3.
- $c\_becomes_3$ : The signal violates the semantics of the pattern by satisfying the negation of the pattern constraint (i.e.,  $\lambda, [t_l, t_u] \models s$  **becomes**  $\not\sim v$  holds).

4. To minimize cluttering, hereafter we omit to indicate that each signal value is associated with a signal name.

---

$\lambda \models \mathbf{c\_not}_1 \text{ sc}$  iff  $\lambda \models \text{sc}$ . The atom  $\text{sc}$  is satisfied.

$\lambda \models \mathbf{c\_a\_at}_1$  iff  $t < t_i \vee t_e < t$ . The value of  $t$  is not within the time interval  $[t_i, t_e]$ .

$\lambda \models \mathbf{c\_a\_bef}_1$  iff  $t \leq t_i \vee t_e < t$ . The value of  $t$  is not within the time interval  $[t_i, t_e]$ .

$\lambda \models \mathbf{c\_a\_aft}_1$  iff  $t < t_i \vee t_e \leq t$ . The value of  $t$  is not within the time interval  $[t_i, t_e]$ .

$\lambda \models \mathbf{c\_a\_bet}_1$  iff  $n < t_i \vee t_e < m \vee m \leq n$ . Either the value of  $n$  or  $m$  is not within  $[t_i, t_e]$ , or the value of  $n$  is not smaller than  $m$ .

$\lambda \models \mathbf{c\_e\_bef}_1$  iff  $\exists t_1, t_2, (t_i < t_1 < t_2 \leq t_e \wedge \lambda, [t_1, t_2] \models p_1 \wedge \forall t_3, t_4, (t_i \leq t_3 < t_4 < t_1 \Rightarrow \lambda, [t_3, t_4] \not\models p))$ . Pattern  $p_1$  holds within  $[t_1, t_2]$ . Pattern  $p$  is violated before  $p_1$ .

$\lambda \models \mathbf{c\_e\_aft}_1$  iff  $\exists t_1, t_2, (t_i \leq t_1 < t_2 < t_e \wedge \lambda, [t_1, t_2] \models p_1 \wedge \forall t_3, t_4, (t_2 < t_3 < t_4 \leq t_e \Rightarrow \lambda, [t_3, t_4] \not\models p))$ . Pattern  $p_1$  holds within  $[t_1, t_2]$ . Pattern  $p$  is violated after  $p_1$ .

$\lambda \models \mathbf{c\_e\_bet}_1$  iff  $\exists t_1, t_2, t_3, t_4, (t_i \leq t_1 < t_2 < t_3 < t_4 \leq t_e \wedge \lambda, [t_1, t_2] \models p_1 \wedge \lambda, [t_3, t_4] \models p_2 \wedge \lambda, [t_2, t_3] \not\models p)$ . Pattern  $p_1$  holds within  $[t_1, t_2]$  and pattern  $p_2$  holds within  $[t_3, t_4]$ , but pattern  $p$  does not hold between  $p_1$  and  $p_2$ .

---

$\lambda, [t_l, t_u] \models \mathbf{c\_assert}_1$  iff  $\exists t \in [t_l, t_u], (\lambda, t \not\models \text{c})$ . There exists a timestamp  $t$  within  $[t_l, t_u]$  in which condition  $\text{c}$  is violated

$\lambda, [t_l, t_u] \models \mathbf{c\_becomes}_1$  iff  $\forall t \in (t_l, t_u), (\mathbf{s}(t) \not\sim \mathbf{v})$ . The signal values violate the pattern constraint  $\sim \mathbf{v}$  throughout the time interval, delimited by  $t_l$  and  $t_u$ , over which the pattern is evaluated.

$\lambda, [t_l, t_u] \models \mathbf{c\_becomes}_2$  iff  $\forall t \in (t_l, t_u), (\exists t_1 \in [t_l, t), (\mathbf{s}(t_1) \sim \mathbf{v}))$ . All the signal values observed within the time interval  $[t_l, t_u]$  satisfy the pattern constraint  $\sim \mathbf{v}$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_becomes}_3$  iff  $\exists t \in (t_l, t_u), (\forall t_1 \in [t_l, t), (\mathbf{s}(t_1) \sim \mathbf{v}) \wedge \forall t_2 \in (t, t_u], (\mathbf{s}(t_2) \not\sim \mathbf{v}))$ . The signal satisfies the semantics of the pattern instance in which the constraint  $\sim \mathbf{v}$  is negated (i.e.,  $\lambda, [t_l, t_u] \models \mathbf{s\ becomes} \not\sim \mathbf{v}$  holds).

$\lambda, [t_l, t_u] \models \mathbf{c\_spike}_1$  iff  $\forall t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], ((t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_min}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_max}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_4, [t_3, t_5])) \Rightarrow \neg(\text{amp}(\mathbf{s}, t_1, t_2, t_3) \sim \mathbf{v}_2))$ . All the spike instances violate the amplitude constraint\*.

$\lambda, [t_l, t_u] \models \mathbf{c\_spike}_2$  iff  $\forall t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], ((t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_min}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_max}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_4, [t_3, t_5])) \Rightarrow \neg(\text{width}(t_2, t_4) \sim \mathbf{v}_1))$ . All the spike instances violate the width constraint\*.

$\lambda, [t_l, t_u] \models \mathbf{c\_spike}_3$  iff  $\forall t \in [t_l, t_u], (\mathbf{s}(t) = \mathbf{s}(t_l))$ . The signal  $\mathbf{s}$  is constant.

$\lambda, [t_l, t_u] \models \mathbf{c\_spike}_4$  iff  $\forall t_1 \in [t_l, t_u), (\forall t_2 \in (t_1, t_u), (\mathbf{s}(t_1) \geq \mathbf{s}(t_2)))$ . The signal  $\mathbf{s}$  decreases.

$\lambda, [t_l, t_u] \models \mathbf{c\_spike}_5$  iff  $\forall t_1 \in [t_l, t_u), (\forall t_2 \in (t_1, t_u), (\mathbf{s}(t_1) \leq \mathbf{s}(t_2)))$ . The signal  $\mathbf{s}$  increases.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_1$  iff  $\forall t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], ((t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_min}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_max}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_4, [t_3, t_5])) \Rightarrow \neg(\text{p2p}(\mathbf{s}, t_2, t_3) \sim \mathbf{v}_2) \wedge \neg(\text{p2p}(\mathbf{s}, t_3, t_4) \sim \mathbf{v}_2))$ . All the oscillation instances violate the amplitude constraint.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_2$  iff  $\forall t_1, t_2, t_3, t_4, t_5 \in [t_l, t_u], ((t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_min}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_max}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_4, [t_3, t_5])) \Rightarrow \neg(\text{width}(t_2, t_4) \sim \mathbf{v}_1))$ . All the oscillation instances violate the period constraint.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_3$  iff  $\exists t_1, t_2, t_3 \in [t_l, t_u], (t_1 < t_2 < t_3 \wedge \text{ext}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \forall t_4, t_5, t_6 \in [t_l, t_u], ((t_5 \neq t_2 \wedge t_4 < t_5 < t_6) \Rightarrow \neg \text{ext}(\mathbf{s}, t_5, [t_4, t_6])))$ . The signal  $\mathbf{s}$  contains only one strict local extremum (minimum or maximum).

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_4$  iff  $\exists t_1, t_2, t_3 \in [t_l, t_u], (t_1 < t_2 < t_3 \wedge \text{ext}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \exists t_4, t_5, t_6 \in [t_l, t_u], (t_5 \neq t_2 \wedge t_4 < t_5 < t_6 \wedge \text{ext}(\mathbf{s}, t_5, [t_4, t_6]) \wedge \forall t_7, t_8, t_9 \in [t_l, t_u], (t_2 \neq t_8 \neq t_5 \wedge t_7 < t_8 < t_9 \wedge \neg \text{ext}(\mathbf{s}, t_8, [t_7, t_9])))$ . The signal  $\mathbf{s}$  shows only two local extrema.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_5$  iff  $\forall t \in [t_l, t_u], (\mathbf{s}(t) = \mathbf{s}(t_l))$ . The signal  $\mathbf{s}$  is constant.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_6$  iff  $\forall t_1 \in [t_l, t_u), (\forall t_2 \in (t_1, t_u), (\mathbf{s}(t_1) \geq \mathbf{s}(t_2)))$ . The signal  $\mathbf{s}$  decreases.

$\lambda, [t_l, t_u] \models \mathbf{c\_oscillation}_7$  iff  $\forall t_1 \in [t_l, t_u), (\forall t_2 \in (t_1, t_u), (\mathbf{s}(t_1) \leq \mathbf{s}(t_2)))$ . The signal  $\mathbf{s}$  increases.

$\lambda, [t_l, t_u] \models \mathbf{c\_rises}_1$  iff  $\forall t \in [t_l, t_u], (\mathbf{s}(t) < \mathbf{v})$ . The signal value is always below  $\mathbf{v}$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_rises}_2$  iff  $\forall t \in [t_l, t_u], (\mathbf{s}(t) \geq \mathbf{v})$ . The signal value is always greater than or equal to  $\mathbf{v}$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_rises}_3$  iff  $\exists t \in (t_l, t_u), (\mathbf{s}(t) \geq \mathbf{v} \wedge \forall t_1 \in [t_l, t), (\mathbf{s}(t_1) < \mathbf{v}) \wedge \neg(\text{mon}(\mathbf{s}, t_1, t)))$ . The signal rises at timestamp  $t$ , reaching value  $\mathbf{v}$ . However, it violates the monotonicity constraint defined in the pattern.

$\lambda, [t_l, t_u] \models \mathbf{c\_rises}_4$  iff  $\exists t \in (t_l, t_u), (\forall t_1 \in [t_l, t), (\mathbf{s}(t_1) \geq \mathbf{v}) \wedge \forall t_2 \in (t, t_u], (\mathbf{s}(t_2) < \mathbf{v}))$ . The value of the signal is initially above the threshold value  $\mathbf{v}$ . The signal then drops and remains below that value.

$\lambda, [t_l, t_u] \models \mathbf{c\_overshoots}_1$  iff  $\forall t \in [t_l, t_u], (\mathbf{s}(t) < \mathbf{v}_1)$ . The signal  $\mathbf{s}$  is always below  $\mathbf{v}_1$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_overshoots}_2$  iff  $\exists t \in [t_l, t_u], (\mathbf{s}(t) > \mathbf{v}_1 + \mathbf{v}_2 \wedge \forall t_1 \in (t, t_u), (\mathbf{s}(t_1) > \mathbf{v}_1 + \mathbf{v}_2))$ . The signal  $\mathbf{s}$  exceeds (and remains above) the value  $\mathbf{v}_1 + \mathbf{v}_2$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_overshoots}_3$  iff  $\exists t \in (t_l, t_u), (\mathbf{s}(t) \geq \mathbf{v}_1 \wedge \mathbf{s}(t) \leq \mathbf{v}_1 + \mathbf{v}_2 \wedge \forall t_2 \in [t_l, t), (\mathbf{s}(t_2) \leq \mathbf{v}_1) \wedge \forall t_1 \in (t, t_u], (\mathbf{s}(t_1) \leq \mathbf{v}_1 + \mathbf{v}_2) \wedge \neg(\text{mon}(\mathbf{s}, t_1, t)))$ . The signal overshoots value  $\mathbf{v}_1$ , without exceeding the maximum threshold set to  $\mathbf{v}_1 + \mathbf{v}_2$ , but it violates the monotonicity constraint.

$\lambda, [t_l, t_u] \models \mathbf{c\_overshoots}_4$  iff  $\exists t \in (t_l, t_u), (\forall t_1 \in [t_l, t), (\mathbf{s}(t_1) \geq \mathbf{v}_1 \wedge \mathbf{s}(t_1) \leq \mathbf{v}_1 + \mathbf{v}_2) \wedge \forall t_2 \in (t, t_u], (\mathbf{s}(t_2) < \mathbf{v}_1))$ . The signal undershoots, going below  $\mathbf{v}_1$  after timestamp  $t$ , and remains below that value instead of overshooting.

$\lambda, [t_l, t_u] \models \mathbf{c\_if-then}$  iff  $\exists t_1, t_2 \in [t_l, t_u], (\lambda, [t_1, t_2] \models \mathbf{p}_1 \wedge (\forall t_3, t_4 \in [t_2, t_u], (\lambda, [t_3, t_4] \not\models \mathbf{p}_2)))$ . Pattern  $\mathbf{p}_1$  holds within the time interval  $[t_1, t_2]$ . Pattern  $\mathbf{p}_2$  never holds after the satisfaction of pattern  $\mathbf{p}_1$ , until the end of the time interval, right-bounded by value  $t_u$ .

$\lambda, [t_l, t_u] \models \mathbf{c\_if-then}$  iff  $\exists t_1, t_2 \in [t_l, t_u], (\lambda, [t_1, t_2] \models \mathbf{p}_1 \wedge \forall t_3, t_4 \in [t_2, t_u], (\lambda, [t_3, t_4] \models \mathbf{p}_2 \Rightarrow \neg((t_3 - t_2) \llbracket \times \rrbracket \mathbf{d})))$  where  $\llbracket \times \rrbracket \mathbf{d}$  is such that  $\llbracket \text{exactly} \rrbracket \equiv '=$ ,  $\llbracket \text{at most} \rrbracket \equiv '<='$ ,  $\llbracket \text{at least} \rrbracket \equiv '>='$ . Pattern  $\mathbf{p}_1$  is satisfied within the time interval  $[t_1, t_2]$ . Any time interval  $[t_3, t_4]$  satisfying pattern  $\mathbf{p}_2$  violates the time distance constraint on the size of  $t_3 - t_2$ .

---

\* We present the case where a (strict) minimum is followed by a strict maximum followed by a (strict) minimum. The dual case can be derived from our formulation.

$\text{ext}(\mathbf{s}, t_2, [t_1, t_3]) = (\text{uni\_sm\_max}(\mathbf{s}, t_2, [t_1, t_3]) \vee \text{uni\_sm\_min}(\mathbf{s}, t_2, [t_1, t_3])); \quad \text{p2p}(\mathbf{s}, t_1, t_2) = |\mathbf{s}(t_1) - \mathbf{s}(t_2)|;$   
 $\text{amp}(\mathbf{s}, t_1, t_2, t_3) = \max(|\mathbf{s}(t_2) - \mathbf{s}(t_1)|, |\mathbf{s}(t_2) - \mathbf{s}(t_3)|); \quad \text{width}(t_1, t_2) = (|t_2 - t_1|)$

Figure 6. Violation causes for the constructs of SB-TemPsy-DSL

---

**d\_not\_assert** =  $\langle t, \mathbf{s}_1(t), \mathbf{s}_2(t), \dots, \mathbf{s}_n(t) \mid (\lambda, t \models c) \rangle$ . One timestamp and all the corresponding signal values where condition  $c$  is satisfied.

**d\_not\_becomes** =  $\langle t, \mathbf{s}(t) \mid t \in (t_l, t_u), (\mathbf{s}(t) \sim v \wedge \forall t_1 \in [t_l, t), (\mathbf{s}(t_1) \not\sim v)) \rangle$ . The first record that satisfies  $\mathbf{s}(t) \sim v$ , such that  $\mathbf{s}(t_1) \not\sim v$  for any time  $t_1$  before  $t$ .

**d\_not\_spike** =  $\langle (t_1, \mathbf{s}(t_1)), (t_5, \mathbf{s}(t_5)) \mid \exists t_2, t_3, t_4 \in [t_l, t_u], (t_l < t_1 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_m\_max}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_m\_max}(\mathbf{s}, t_4, [t_3, t_5])) [[\wedge (t_3 - t_1) \sim_1 v_1]_\beta [\wedge \max((\mathbf{s}(t_2) - \mathbf{s}(t_3)), (\mathbf{s}(t_4) - \mathbf{s}(t_5))) \sim_2 v_2]_\gamma]_\alpha \rangle$ . The first  $\langle t_1, \mathbf{s}(t_1) \rangle$  and the last  $\langle t_5, \mathbf{s}(t_5) \rangle$  records that show an occurrence of a spike\*.

**d\_not\_oscillation** =  $\langle (t_1, \mathbf{s}(t_1)), (t_5, \mathbf{s}(t_5)) \mid \exists t_2, t_3, t_4 \in [t_l, t_u], (t_l < t_2 < t_2 < t_3 < t_4 < t_5 \wedge \text{uni\_sm\_max}(\mathbf{s}, t_2, [t_1, t_3]) \wedge \text{uni\_sm\_min}(\mathbf{s}, t_3, [t_2, t_4]) \wedge \text{uni\_sm\_max}(\mathbf{s}, t_4, [t_3, t_5])) [[\wedge (t_4 - t_2) \sim_1 v_1]_\zeta [\wedge (\mathbf{s}(t_2) - \mathbf{s}(t_3)) \sim_2 v_2 \wedge (\mathbf{s}(t_4) - \mathbf{s}(t_5)) \sim_2 v_2]_\epsilon]_\delta \rangle$ . The first  $\langle t_1, \mathbf{s}(t_1) \rangle$  and the last  $\langle t_5, \mathbf{s}(t_5) \rangle$  records that show an occurrence of oscillations\*.

**d\_not\_rises** =  $\langle t, \mathbf{s}(t) \mid t \in (t_l, t_u), (\mathbf{s}(t) \geq v \wedge \forall t_1 \in [t_l, t), (\mathbf{s}(t_1) < v) [\wedge \text{mon}(\mathbf{s}, t_l, t)]_\alpha \rangle$ . The first record  $\langle t, \mathbf{s}(t) \rangle$  at which the signal becomes greater than or equal to  $v$ , where the optional monotonicity constraint is satisfied, if defined in the property.

**d\_not\_overshoots** =  $\langle t, \mathbf{s}(t) \mid t \in (t_l, t_u), (\mathbf{s}(t) \geq v_1 \wedge \forall t_1 \in [t_l, t_u), (\mathbf{s}(t_1) \leq v_1 + v_2) \wedge \forall t_2 \in [t_l, t), (\mathbf{s}(t_2) < v_1) [\wedge \text{mon}(\mathbf{s}, t_l, t)]_\alpha \rangle$ . The first record at which signal  $\mathbf{s}$  reaches value  $v_1$ . The signal never goes above the maximum allowed amplitude of  $v_1 + v_2$  and satisfies the monotonicity constraint, if defined in the property.

**d\_not\_if-then** =  $\langle [t_1, t_2], [t_3, t_4] \mid (t_l < t_1 < t_2 < t_3 < t_4 < t_u \wedge \lambda, [t_1, t_2] \models p_1 \wedge \lambda, [t_3, t_4] \models p_2 [\wedge (t_3 - t_2) [\bowtie] d]_\alpha \rangle$ . An interval  $[t_1, t_2]$  where pattern  $p_1$  holds and a subsequent interval  $[t_3, t_4]$  where pattern  $p_2$  holds.

---

**d\_a\_at**/**d\_a\_bef**<sub>1</sub>/**d\_a\_aft**<sub>1</sub> =  $\langle [t_i, t_e], t \rangle$ . The time interval  $[t_i, t_e]$  and the absolute boundary  $t$ , that is not within that interval.

**d\_a\_bet**<sub>1</sub> =  $\langle [t_i, t_e], n, m \rangle$ . Values  $n$  and  $m$  and the interval  $[t_i, t_e]$ .

**d\_e\_bef**<sub>1</sub> =  $\langle [t_1, t_2] \mid (t_l < t_1 < t_2 \leq t_u \wedge \lambda, [t_1, t_2] \models p_1 \wedge \forall t_3, t_4, (t_l \leq t_3 < t_4 < t_1 \Rightarrow \lambda, [t_3, t_4] \not\models p) \rangle$ . The interval  $[t_1, t_2]$  where  $p_1$  holds, and before which the property pattern  $p$  failed to hold.

**d\_e\_aft**<sub>1</sub> =  $\langle [t_1, t_2] \mid (t_l \leq t_1 < t_2 < t_u \wedge \lambda, [t_1, t_2] \models p_1 \wedge \forall t_3, t_4, (t_2 < t_3 < t_4 \leq t_u \Rightarrow \lambda, [t_3, t_4] \not\models p) \rangle$ . The interval  $[t_1, t_2]$ , where  $p_1$  holds and after which the property pattern  $p$  failed to hold.

**d\_e\_bet**<sub>1</sub> =  $\langle [t_2, t_3] \mid (\exists t_1 \in [t_l, t_u), t_1 \leq t_1 < t_2 < t_3 < t_u \wedge \lambda, [t_1, t_2] \models p_1 \wedge \exists t_4 \in (t_3, t_u), t_3 < t_4 \leq t_u \wedge \lambda, [t_3, t_4] \models p_2 \wedge \lambda, [t_2, t_3] \not\models p) \rangle$ . The time interval  $[t_2, t_3]$ , where  $t_2$  is the last timestamp in which pattern  $p_1$  held and  $t_3$  is the first timestamp in which pattern  $p_2$  held.

---

Figure 7. Diagnoses associated with the violation causes of atoms and scopes in Figure 6.

For instance, signal  $\beta_3$  in the figure becomes less than or equal to 3 (instead of becoming greater than 3). More precisely, it goes below value 3 at timestamps 4, and remains below that value until the end of the time interval, delimited by timestamp 7.

**Diagnoses:** The diagnoses associated with the three violation causes above are the following:

- **d\_becomes**<sub>1</sub> and **d\_becomes**<sub>2</sub> include two records from the signal showing a minimum and a maximum value. In this way, we show the range of values over which the signal changes. In the example shown in Figure 10, we report records  $\langle (7, 2.8), (4, 0.5) \rangle$  for signal  $\beta_1$  and records  $\langle (0.5, 5), (5, 3.3) \rangle$  for signal  $\beta_2$ .
- **d\_becomes**<sub>3</sub> includes the last-seen record at which the signal value satisfies the constraint  $\sim v$ , followed by the next-seen record at which the signal value satisfies  $\not\sim v$ . Through this diagnosis, we want to capture the exact time interval, delimited by two consecutive timestamps, within  $[t_l, t_u]$ , in which the signal exhibits a behavior compatible with the negation of the constraint specified in the **becomes** expression. For instance, for signal  $\beta_3$  in Figure 10, the diagnosis is  $\langle (3, 4.3), (4, 0.8) \rangle$ .

### 6.1.3 Spike

**Violation causes:** This pattern can be violated in at least five ways, as illustrated with different signal behaviors in Figure 5 using the expression “**exists spike in  $\beta$  with amplitude  $< 90$  width  $< 0.5$** ”. These alternatives are the following:

- **c\_spike**<sub>1</sub>: All spike instances in the signal violate the amplitude constraint. For instance, signal  $\beta_1$  in the figure shows two spike amplitude values greater than 90 (150 and 200, respectively).
- **c\_spike**<sub>2</sub>: All spike instances in the signal violate the width constraint. For example, signal  $\beta_1$  shows two spike width values greater than 0.5 (1.8 and 4.2, respectively).

- **c\_spike**<sub>3</sub>: The signal is constant throughout the time interval over which the pattern is evaluated. For example, the constant signal  $\beta_2$  in the figure always takes the value 100 within the time interval  $[0, 6]$ .
- **c\_spike**<sub>4</sub>: The signal decreases, within the time interval over which the pattern is evaluated, without showing any spike behavior. For example, signal  $\beta_3$  in the figure decreases within the time interval  $[0, 6]$ , going from value 190 to 30.
- **c\_spike**<sub>5</sub>: The signal increases within the time interval over which the pattern is evaluated, without showing any spike behavior. For instance, signal  $\beta_4$  increases within the time interval  $[0, 6]$ , going from value 30 to 190.

**Diagnoses:** The diagnoses associated with the five violation causes above are the following:

- **d\_spike**<sub>1</sub> includes the time interval in which the spike with the closest amplitude to satisfy the amplitude constraint occurs, as well as the amplitude value of that spike instance (see page 5 for a detailed explanation). The intuition behind this diagnosis is that when a spike property with an amplitude constraint is violated, the engineers are interested in knowing the amplitude value of the spike that is the closest to satisfy the amplitude constraint, to assess how close the signal behavior was to satisfy the property. For instance, for signal  $\beta_1$  in Figure 5, the diagnosis is  $\langle [0, 1.8], 150 \rangle$ .
- **d\_spike**<sub>2</sub> is defined in a similar way, but with respect to the width constraint. It includes the time interval in which the spike with the closest width to satisfy the width constraint occurs, as well as the width value of that spike instance. Similar to **d\_spike**<sub>1</sub>, the choice of this specific width value enables engineers to determine the closest value of a spike width to the satisfaction of the width constraint defined in the pattern. For instance, for signal  $\beta_1$  in Figure 5, the diagnosis is  $\langle [0, 1.8], 1.8 \rangle$ .

**d\_assert**<sub>1</sub> =  $\langle t, s_1(t), s_2(t), \dots, s_n(t) \mid (\lambda, t \not\models c) \wedge \forall t_1 \in [t_l, t], (\lambda, t_1 \models c) \rangle$ . The first timestamp  $t$  and the values, taken in correspondence of  $t$ , of the signals that lead to the violation of condition  $c$ .

**d\_becomes**<sub>1</sub>/**d\_becomes**<sub>2</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \forall t \in [t_l, t_u], (s(t) \leq s(t_1) \wedge s(t) \geq s(t_2)) \rangle$ . The maximum and the minimum values (and the corresponding timestamps) of signal  $s$ .

**d\_becomes**<sub>3</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid t_l \leq t_1 < t_2 \leq t_u \wedge s(t_1) \sim v \wedge s(t_2) \not\sim v \wedge \neg \exists t_3 \in [t_l, t_u], (t_1 < t_3 < t_2) \rangle$ . The last time instant  $t_1$  (and the corresponding value) at which the signal  $s$  satisfies the predicate  $s(t_1) \sim v$ , exactly followed by the next time instant  $t_2$  (and the corresponding value) at which the signal value satisfies the predicate  $s(t_2) \not\sim v$ .

**d\_spike**<sub>1</sub> =  $\langle [t_l, t_2], a \mid (\exists t_3, t_4, t_5 \in [t_l, t_u], (spk(s, t_3, t_1, t_4, t_2, t_5) \wedge \neg(amp(s, t_1, t_4, t_2) \sim_2 v_2) \wedge a = amp(s, t_1, t_4, t_2) \wedge \forall t_6, t_7, t_8, t_9, t_{10} \in [t_l, t_u], ((t_7 \neq t_1 \wedge t_8 \neq t_4 \wedge t_9 \neq t_2 \wedge spk(s, t_6, t_7, t_8, t_9, t_{10})) \Rightarrow |a - v_2| < ampv(s, t_7, t_8, t_9, v_2)))) \rangle$ . The amplitude  $a$  and the interval  $[t_l, t_2]$  of the spike that is the closest to satisfy the amplitude constraint.

**d\_spike**<sub>2</sub> =  $\langle [t_l, t_2], w \mid (\exists t_3, t_4, t_5 \in [t_l, t_u], (spk(s, t_3, t_1, t_4, t_2, t_5) \wedge \neg(width(t_1, t_2) \sim_1 v_1) \wedge w = width(t_1, t_2) \wedge \forall t_6, t_7, t_8, t_9, t_{10} \in [t_l, t_u], ((t_7 \neq t_1 \wedge t_8 \neq t_4 \wedge t_9 \neq t_2 \wedge spk(s, t_6, t_7, t_8, t_9, t_{10})) \Rightarrow |w - v_1| < widthv(t_7, t_9, v_1)))) \rangle$ . The width  $w$  and the time interval  $[t_l, t_2]$  of the spike that is the closest to satisfy the width constraint.

**d\_spike**<sub>3</sub> =  $\langle [t_l, t_u], s(t_l) \rangle$ . The first and the last timestamps ( $t_l$  and  $t_u$ ) delimiting the interval throughout which signal  $s$  is constant, and the signal value.

**d\_spike**<sub>4</sub>/**d\_spike**<sub>5</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \forall t \in [t_l, t_u], (s(t) \leq s(t_1) \wedge s(t) \geq s(t_2)) \rangle$ . The maximum and the minimum values (and their timestamps) taken by signal  $s$ .

**d\_oscillation**<sub>1</sub> =  $\langle [t_l, t_5], a \mid (\exists t_2, t_3, t_4 \in [t_l, t_u], (osc(s, t_1, t_2, t_3, t_4, t_5) \wedge \neg(p2p(s, t_2, t_3) \sim_2 v_2 \vee p2p(s, t_3, t_4) \sim_2 v_2) \wedge a = \max(p2p(s, t_2, t_3), p2p(s, t_3, t_4)) \wedge \forall t_6, t_7, t_8, t_9, t_{10} \in [t_l, t_u], ((t_8 \neq t_2 \wedge t_9 \neq t_3 \wedge t_{10} \neq t_4 \wedge osc(s, t_6, t_8, t_9, t_{10}, t_7)) \Rightarrow (|a - v_2| \leq p2pv(s, t_8, t_9, v_2) \wedge |a - v_2| \leq p2pv(s, t_9, t_{10}, v_2)))) \rangle$ . The amplitude  $a$  and the time interval  $[t_l, t_5]$  of the closest oscillation instance to satisfy the amplitude constraint.

**d\_oscillation**<sub>2</sub> =  $\langle [t_l, t_5], w \mid (\exists t_2, t_3, t_4 \in [t_l, t_u], (osc(s, t_1, t_2, t_3, t_4, t_5) \wedge \neg(width(t_2, t_4) \sim_1 v_1) \wedge w = width(t_2, t_4) \wedge \forall t_6, t_7, t_8, t_9, t_{10} \in [t_l, t_u], ((t_8 \neq t_2 \wedge t_9 \neq t_3 \wedge t_{10} \neq t_4 \wedge osc(s, t_6, t_8, t_9, t_{10}, t_7)) \Rightarrow (|w - v_1| < widthv(t_8, t_{10}, v_1)))) \rangle$ . The period  $w$  and the interval  $[t_l, t_2]$  of the closest oscillations instance to satisfy the period constraint.

**d\_oscillation**<sub>3</sub> =  $\langle t_1, s(t_1) \mid \exists t_2, t_3 \in [t_l, t_u], t_l \leq t_2 < t_1 < t_3 \leq t_u \wedge (uni\_sm\_min(s, t_1, [t_2, t_3]) \vee uni\_sm\_max(s, t_1, [t_2, t_3])) \rangle$ . The record at which the only seen strict extremum occurs in the signal, within the time interval  $[t_l, t_u]$ .

**d\_oscillation**<sub>4</sub> =  $\langle (t_1, s(t_1)), (t_4, s(t_4)) \mid \exists t_2, t_3 \in [t_l, t_u], t_l \leq t_2 < t_1 \wedge t_1 < t_4 \wedge t_4 < t_3 \leq t_u \wedge (uni\_sm\_min(s, t_1, [t_2, t_4]) \vee uni\_sm\_max(s, t_1, [t_2, t_4])) \wedge (uni\_sm\_min(s, t_4, [t_1, t_3]) \vee uni\_sm\_max(s, t_4, [t_1, t_3])) \wedge t_4 \neq t_1 \rangle$ . The two records at which the strict maximum and the strict minimum occur in the signal, within the time interval  $[t_l, t_u]$ .

**d\_oscillation**<sub>5</sub> =  $\langle [t_l, t_u], s(t_l) \rangle$ . The first and the last timestamps ( $t_l$  and  $t_u$ ) delimiting the interval throughout which signal  $s$  is constant, and the signal value.

**d\_oscillation**<sub>6</sub>/**d\_oscillation**<sub>7</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \forall t \in [t_l, t_u], (s(t) \leq s(t_1) \wedge s(t) \geq s(t_2)) \rangle$ . The maximum and the minimum values (and their timestamps) taken by the signal  $s$ .

**d\_rises**<sub>1</sub>/**d\_rises**<sub>2</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \forall t \in [t_l, t_u], (s(t) \leq s(t_1) \wedge s(t) \geq s(t_2)) \rangle$ . The maximum and the minimum values (and their timestamps) of signal  $s$ .

**d\_rises**<sub>3</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \neg(\exists t \in [t_l, t_u], (t_1 < t < t_2)) \wedge \exists t \in (t_l, t_u), (s(t) \geq v \wedge \forall t_3 \in [t_l, t], (s(t_3) < v) \wedge t_1 < t_2 < t \wedge s(t_1) > s(t_2)) \rangle$ . Two signal values that violate the monotonicity constraint and the corresponding consecutive timestamps  $t_1$  and  $t_2$ .

**d\_rises**<sub>4</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid t_l \leq t_1 < t_2 \leq t_u \wedge s(t_1) \geq v \wedge s(t_2) < v \wedge \neg \exists t \in [t_l, t_u], (t_1 < t < t_2) \rangle$ . The record at which the signal  $s$  is greater than or equal to value  $v$ , followed by the record at which the signal falls, going below  $v$ .

**d\_overshoots**<sub>1</sub>/**d\_overshoots**<sub>2</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid \forall t \in [t_l, t_u], (s(t) \leq s(t_1) \wedge s(t) \geq s(t_2)) \rangle$ . The maximum and the minimum values (and timestamps) of signal  $s$ .

**d\_overshoots**<sub>3</sub> =  $\langle t_1, s(t_1), t_2, s(t_2) \mid \neg(\exists t \in [t_l, t_u], (t_1 < t < t_2)) \wedge \exists t \in (t_l, t_u), (s(t) \geq v_1 \wedge \forall t_4 \in [t_l, t], (s(t_4) \leq v_1) \wedge \forall t_5 \in [t, t_u], (s(t_5) \leq v_1 + v_2) \wedge (t_l < t_1 < t_2 < t) \wedge s(t_1) \geq s(t_2)) \rangle$ . Two consecutive records of a signal that overshoots, but does not satisfy the monotonicity constraint.

**d\_overshoots**<sub>4</sub> =  $\langle (t_1, s(t_1)), (t_2, s(t_2)) \mid t_l \leq t_1 < t_2 \leq t_u \wedge s(t_1) \geq v_1 \wedge s(t_1) \leq v_1 + v_2 \wedge s(t_2) < v_1 \wedge \neg \exists t \in [t_l, t_u], (t_1 < t < t_2) \rangle$ . The record at which the signal  $s$  is greater than or equal to value  $v_1$  and less than or equal to  $v_1 + v_2$ , followed by the record at which the signal undershoots, going below  $v_1$ .

**d\_if-then**<sub>1</sub> =  $\langle [t_2, t_u] \mid (\exists t_1 \in [t_l, t_2], \lambda, [t_1, t_2] \models p_1 \wedge \forall t_3, t_4 \in (t_2, t_u], (\lambda, [t_3, t_4] \not\models p_2)) \rangle$ . The time interval delimited by  $t_2$  (the last time instant of the last occurrence of pattern  $p_1$ ) up to the last time instant ( $t_u$ ) of the trace.

**d\_if-then**<sub>2</sub> =  $\langle [t_2, t_3], t_3 - t_2 \mid (\exists t_1 \in [t_l, t_2], \lambda, [t_1, t_2] \models p_1 \wedge \exists t_4 \in (t_3, t_u], (\lambda, [t_3, t_4] \models p_2 \Rightarrow \neg((t_3 - t_2) \llbracket \times \rrbracket d) \wedge \forall t_5, t_6 \in (t_2, t_3), (\lambda, [t_5, t_6] \not\models p_2)) \rangle$ . The time interval  $[t_2, t_3]$  representing the time distance between patterns  $p_1$  and  $p_2$  hold, and the exact value of that violated time distance ( $t_3 - t_2$ ).

\*  $spk(s, t_1, t_2, t_3, t_4, t_5) = uni\_m\_min(s, t_2, [t_1, t_3]) \wedge uni\_sm\_max(s, t_3, [t_2, t_4]) \wedge uni\_m\_min(s, t_4, [t_3, t_5])$

\*  $osc(s, t_1, t_2, t_3, t_4, t_5) = uni\_sm\_min(s, t_2, [t_1, t_3]) \wedge uni\_sm\_max(s, t_3, [t_2, t_4]) \wedge uni\_sm\_min(s, t_4, [t_3, t_5])$

$ampv(s, t_1, t_2, t_3, v) = |amp(s, t_1, t_2, t_3) - v|$ ;  $p2pv(s, t_1, t_2, v) = |p2p(s, t_1, t_2) - v|$ ;  $widthv(t_1, t_2, v) = |width(t_1, t_2) - v|$

Figure 8. Diagnoses associated with the violation causes of patterns in Figure 6.

- **d\_spike**<sub>3</sub> includes the time interval  $[t_l, t_u]$  over which the property pattern is evaluated, as well as the value taken by the constant signal throughout that interval. This diagnosis shows that the signal is constant (i.e., it shows a single value) throughout the full time interval  $[t_l, t_u]$ , over which the pattern is evaluated. For instance, for signal  $\beta_2$  in Figure 5, the diagnosis is  $\langle [0, 6], 100 \rangle$ .
- **d\_spike**<sub>4</sub> and **d\_spike**<sub>5</sub> include two records from the signal corresponding to its minimum and maximum values (and the timestamps at which these values occur). In this way, we show the range of values over which the signal changes (decreasing or increasing). In the example shown in Figure 5, we report

records  $\langle (0, 200), (6, 55) \rangle$  for the decreasing signal  $\beta_3$  and records  $\langle (0, 30), (6, 190) \rangle$  for the increasing signal  $\beta_4$ .

### 6.1.4 Oscillation

**Violation causes:** This pattern can be violated in at least seven ways, as illustrated with different signal behaviors in Figure 11 using the expression “**exist oscillation in  $\beta$  with  $p2pAmp < 90$  period  $< 0.5$** ”. These alternatives are the following:

- **c\_oscillation**<sub>1</sub>: All oscillation instances in the signal violate the amplitude constraint. For instance, signal  $\beta_1$  in the figure shows two oscillation instances, both

Figure 9. A trace violating the expression “**assert**  $\beta < 4$ ”.

Figure 10. A trace with signals violating the expression “ **$\beta$  becomes**  $> 3$ ”.

having an amplitude value greater than 90 (125 and 200, respectively).

- **c\_oscillation<sub>2</sub>**: All oscillation instances in the signal violate the period constraint. For instance, signal  $\beta_1$  shows two oscillation instances whose period value is greater than 0.5: the first oscillation has a period of 0.8 (i.e., the time difference between timestamps 0.2 and 1), while the second oscillation has a period of 1 (i.e., the time difference between timestamps 3.5 and 4.5).
- **c\_oscillation<sub>3</sub>**: The signal does not show any oscillation; instead, it shows only one strict local extremum (a maximum or a minimum). This is the case, for instance, of signal  $\beta_2$  in the figure, that exhibits a strict local maximum (reaching the value of 150 at timestamp 1.5).
- **c\_oscillation<sub>4</sub>**: The signal does not show any oscillation; instead, it shows only two strict local extrema. For instance, signal  $\beta_3$  in the figure exhibits a strict local minimum (taking value 80 at timestamp 1.5), followed by a strict local maximum (taking value 150 at timestamp 2).
- **c\_oscillation<sub>5</sub>**: The signal is constant throughout the time interval  $[t_l, t_u]$  (see, for example, signal  $\beta_4$  in the figure).
- **c\_oscillation<sub>6</sub>**: The signal decreases without showing any oscillatory behavior. For instance, signal  $\beta_5$  in the figure decreases, going from value 180 at timestamp 0.1 to value 20 at timestamp 5.8.
- **c\_oscillation<sub>7</sub>**: The signal increases without showing any oscillatory behavior. For example, signal  $\beta_6$  in

the figure increases, going from value 40 at timestamp 0.2 to value 150 at timestamp 5.8.

Figure 11. A trace with signals violating the expression “**exist oscillation in**  $\beta$  **with period**  $< 0.5$  **p2pAmp**  $< 90$ ”.

**Diagnoses:** The diagnoses associated with the seven violation causes above are the following:

- **d\_oscillation<sub>1</sub>** includes the time interval in which the oscillation with the closest amplitude to satisfy the amplitude constraint occurs, as well as the amplitude value of that oscillation instance. The choice of this diagnosis enables engineers to determine the oscillation instance with the closest amplitude to the satisfaction of the amplitude constraint defined in the pattern. For instance, for signal  $\beta_1$  in Figure 11, the diagnosis is  $\langle [0, 1.9], 125 \rangle$ .
- **d\_oscillation<sub>2</sub>** includes the time interval in which the oscillation with the closest period to satisfy the period constraint occurs, as well as the period of that oscillation instance. For instance, for signal  $\beta_1$  in Figure 11, the diagnosis is  $\langle [0, 1.9], 0.8 \rangle$ . Similar to **d\_oscillation<sub>1</sub>**, we allow engineers to identify the oscillation instance that shows the closest period value to the satisfaction of the period constraint defined in the pattern.
- **d\_oscillation<sub>3</sub>** includes the timestamp (and the corresponding signal value) in which the signal exhibits a strict extremum. The reported diagnosis allows engineers to identify the first time in which the signal exhibited a considerable deviation, leading to a change of the sign of its derivative. For instance, for signal  $\beta_2$  in Figure 11, the diagnosis is  $\langle 1.5, 150 \rangle$ .
- **d\_oscillation<sub>4</sub>** includes the two records from the signal in which the strict maximum and the strict minimum occur. By considering this diagnosis, engineers are able to see a considerable change of the signal shape, showing two different consecutive strict extrema. For instance, for signal  $\beta_3$  in Figure 11, the diagnosis is  $\langle (1.5, 80), (2, 150) \rangle$ .
- **d\_oscillation<sub>5</sub>** includes the time interval  $[t_l, t_u]$  throughout which the signal  $s$  is constant, as well as the value taken by that signal. Similar to **d\_spike<sub>3</sub>**, this diagnosis shows that the signal is constant throughout the full time interval  $[t_l, t_u]$  over which the pattern is evaluated. For instance, for signal  $\beta_4$  in Figure 11, the diagnosis is  $\langle [0, 6], 180 \rangle$ .

- **d\_oscillation<sub>6</sub>** and **d\_oscillation<sub>7</sub>** include the records in which the maximum and the minimum values of the signal were observed. In this way, we show the range of values over which the signal changes (i.e., decreases or increases). In the example shown in Figure 11, we report records  $\langle(0.1, 180), (5.8, 20)\rangle$  for signal  $\beta_5$  and records  $\langle(0.2, 40), (5.8, 150)\rangle$  for signal  $\beta_6$ .

### 6.1.5 Rise time

**Violation causes:** This pattern can be violated in at least four ways, as illustrated with different signal behaviors in Figure 12 using the expression “ $\beta$  rises monotonically reaching 3”.

- **c\_rises<sub>1</sub>**: The signal is always below the threshold value  $v$  defined in the pattern constraint. For instance, signal  $\beta_1$  is always below the value of 3, showing values ranging between 0.8 and 2.5.
- **c\_rises<sub>2</sub>**: The signal is always greater than or equal to the threshold value  $v$ . For instance, signal  $\beta_2$  is always above the value 3, showing values ranging between 4 and 6.
- **c\_rises<sub>3</sub>**: The signal shows a rising behavior, but violates the monotonicity constraint defined in the pattern. For instance, signal  $\beta_3$  rises reaching the target value (showing a value of 4 at timestamp 4), but it violates the monotonicity constraint since its value decreases from 2 (at timestamp 2) to 0.5 (at timestamp 3).
- **c\_rises<sub>4</sub>**: The signal is initially above the threshold value  $v$ . It then falls (and remains) below that value, instead of rising. For instance, signal  $\beta_4$  falls (and remains) below the target value of 3 (starting from timestamp 4, up to timestamp 7, showing values ranging within the interval  $[0.5, 2]$ ) instead of rising.

Figure 12. A trace with signals violating the expression “ $\beta$  rises monotonically reaching 3”.

**Diagnoses:** The diagnoses associated with the four violation causes above are the following:

- **d\_rises<sub>1</sub>** and **d\_rises<sub>2</sub>** include the records in which the signal shows a maximum and a minimum value. In this way, we show the range of values the signal takes. For instance, for signal  $\beta_1$  in Figure 12, the diagnosis is  $\langle(5, 0.8), (6.7, 2.5)\rangle$ . Similarly, diagnosis for signal  $\beta_2$  is  $\langle(0.5, 4), (7, 6)\rangle$ .
- **d\_rises<sub>3</sub>** includes two consecutive records where the monotonicity constraint is violated. In this way, we

show the exact interval over which the signal deviated from the last time it exhibited an increasing behavior, showing a negative derivative. For instance, for signal  $\beta_3$  in Figure 12, the diagnosis is  $\langle(2, 2), (3, 0.5)\rangle$ .

- **d\_rises<sub>4</sub>** includes two consecutive records in which the signal shows a dual behavior (i.e., it falls instead of rising). More precisely, the signal value in the first record is above the threshold value  $v$ . The signal value in the second reported record is, however, below that value. This diagnosis determines the interval over which the signal shows a dual behavior, within the time interval  $[t_l, t_u]$  over which the pattern is evaluated. For instance, the diagnosis of signal  $\beta_4$  in Figure 12 is  $\langle(3, 3.1), (4, 0.5)\rangle$ .

### 6.1.6 Overshoot

**Violation causes:** This pattern can be violated in at least four ways, as illustrated with different signal behaviors in Figure 13 using the expression “ $\beta$  overshoots monotonically 3 by 1”:

- **c\_overshoots<sub>1</sub>**: The signal violates the pattern constraint, by always showing values below the threshold value  $v_1$ . For example, signal  $\beta_1$  is always below the value of 3.
- **c\_overshoots<sub>2</sub>**: The signal goes beyond the maximum allowed value, which consists of the sum of the target value  $v_1$  and the maximum threshold value  $v_2$  ( $v_1 + v_2$ ), and remains above that value. For instance, signal  $\beta_2$  exceeds 4 (showing a value of 4.5 at timestamp 2) and remains above the value of 4, ranging over  $[4.1, 4.9]$ .
- **c\_overshoots<sub>3</sub>**: The signal overshoots the threshold value  $v_1$ , without going beyond the maximum allowed value (delimited by  $v_1 + v_2$  defined in the pattern). However, it violates the monotonicity constraint. For instance, signal  $\beta_3$  overshoots, reaching the value of 3.8 at timestamp 4, without going beyond the value of 4 after then. It violates the monotonicity constraint within the time interval  $[2, 3]$ , since its value goes from 2 down to 0.5.
- **c\_overshoots<sub>4</sub>**: The signal shows a dual behavior: it undershoots, going below the value  $v_1$ , and remains below that value instead of overshooting. For instance, signal  $\beta_4$  goes (and remains) below the value of 3. It reaches value 2 at timestamp 3 and takes, right after then, values ranging over  $[0.5, 2]$ .

**Diagnoses:** The diagnoses associated with the four violation causes above are the following:

- **d\_overshoots<sub>1</sub>** and **d\_overshoots<sub>2</sub>** include the records in which the signal shows a maximum and a minimum value. The reported diagnosis allows engineers to understand the range of values taken by the signal. For instance, for signal  $\beta_1$  in Figure 13, the diagnosis is  $\langle(5, 0.8), (6.7, 2.5)\rangle$ .
- **d\_overshoots<sub>3</sub>** includes two consecutive records from a signal that overshoots, but violates the monotonicity constraint. This diagnosis shows the time interval over which the signal violated the monotonicity constraint within  $[t_l, t_u]$ . For instance, for signal  $\beta_3$  in Figure 13, the diagnosis is  $\langle(2, 2), (3, 0.5)\rangle$

Figure 13. A trace with signals violating the expression “ $\beta$  overshoots monotonically 3 by 1”.

- **d\_overshoots<sub>4</sub>** includes two consecutive records in which the signal shows a dual behavior (i.e., it undershoots instead of overshooting). More specifically, we report the last record at which the signal value is delimited by  $[v_1, v_1 + v_2]$ , followed by the next-seen record at which it undershoots, going below  $v_1$ . This diagnosis allows engineers to understand the interval over which the signal shows a dual behavior within the time interval  $[t_l, t_u]$ . For instance, for signal  $beta_4$  in Figure13, the diagnosis is  $\langle(2, 3.8), (3, 2.1)\rangle$ .

### 6.1.7 Order relationship

**Violation causes:** A property with an **if-then** construct is based on two patterns, each of which represents one of the pattern constructs we support in SB-TemPsy-DSL. According to the construct syntax **if**  $p_1$  **then**  $p_2$ ,  $p_1$  is referred to as a cause pattern and  $p_2$  as an effect pattern. We consider two possible violation causes of a property with the **if-then** construct.

- **c\_if-then<sub>1</sub>**: the cause pattern  $p_1$  holds at some time interval  $[t_1, t_2]$  within the time interval  $[t_l, t_u]$ , but then, the effect pattern  $p_2$  fails to hold until the last timestamp ( $t_u$ ) of that time interval.
- **c\_if-then<sub>2</sub>**: the cause pattern  $p_1$  holds within a time interval  $[t_1, t_2]$  but since then, whenever the effect pattern  $p_2$  holds (after  $p_1$ ) within a time interval  $[t_3, t_4]$ , the time distance ( $t_3 - t_2$ ) between the occurrences of two patterns  $p_1$  and  $p_2$  is violated.

**Diagnoses:** The diagnoses associated with a violation of an expression with an **if-then** construct are the following:

- **d\_if-then<sub>1</sub>** includes the time interval delimited by the last timestamp ( $t_2$ ) of the last occurrence of pattern  $p_1$  and the last timestamp  $t_u$  of the time interval  $[t_l, t_u]$ , showing the exact interval over which the effect pattern  $p_2$  failed to hold. The corresponding diagnosis is then the following:  $\langle[t_2, t_u]\rangle$ .
- **d\_if-then<sub>2</sub>** includes the time interval delimited by the last timestamp ( $t_2$ ) in which the cause pattern  $p_1$  holds, and the first timestamp ( $t_3$ ) in which the effect pattern  $p_2$  holds again. The diagnosis also includes the violated time distance ( $t_3 - t_2$ ) between the occurrence of patterns  $p_1$  and  $p_2$ . The diagnosis is the following:  $\langle[t_2, t_3], t_3 - t_2\rangle$ .

## 6.2 Scopes

Since the same syntactic constructs of SB-TemPsy-DSL (e.g., the keyword **before**) can be used to define both absolute and event scopes (see Figure 3), we use the identifiers **a\_** and **e\_** before the violation cause name depending on whether it refers to an absolute or an event scope. Additionally, we use **bef**, **aft**, and **bet** as shortcuts for **before**, **after**, and **between**, respectively. For example, **c\_a\_bef<sub>2</sub>** denotes a violation cause for the **before** absolute scope.

**Violation causes:**

- **c\_a\_at<sub>1</sub>**, **c\_a\_bef<sub>1</sub>** and **c\_a\_aft<sub>1</sub>** are violations related to absolute boundaries (i.e., timestamps) that are not within the time interval of the trace over which the property is evaluated.
- **c\_a\_bet<sub>1</sub>** indicates that either at least one of the scope boundaries is outside the time interval  $[t_i, t_e]$  or the left boundary (which is supposed to be smaller than the right one) is greater than or equal to the right boundary.
- **c\_e\_bef<sub>1</sub>** states that scope pattern  $p_1$  holds in the execution trace, whereas the property pattern  $p$  fails to hold sometime before  $p_1$  held.
- **c\_e\_aft<sub>1</sub>** indicates that scope pattern  $p_1$  holds in the execution trace, whereas the property pattern  $p$  fails to hold after that.
- **c\_e\_bet<sub>1</sub>** states that scope patterns  $p_1$  and  $p_2$  hold in the execution trace, whereas the property pattern  $p$  fails to hold between the last timestamp where  $p_1$  held and the first timestamp in which  $p_2$  held.

**Diagnoses:** The diagnoses associated with scope-based violations are the following:

- **d\_a\_at<sub>1</sub>**, **d\_a\_bef<sub>1</sub>** and **d\_a\_aft<sub>1</sub>** include the time interval  $[t_i, t_e]$  that delimits the execution trace, as well as the absolute boundary  $t$  that is not within the range delimited by that time interval.
- **d\_a\_bet<sub>1</sub>** includes the time interval  $[t_i, t_e]$  of the execution trace over which the property is evaluated, as well as the left and the right absolute boundaries of the scope (i.e., timestamps  $n$  and  $m$ , respectively; see Figure 3).
- **d\_e\_bef<sub>1</sub>** includes the time interval  $[t_1, t_2]$  in which the scope pattern  $p_1$  held and before which the property pattern  $p$  failed to hold.
- **d\_e\_aft<sub>1</sub>** includes the time interval  $[t_1, t_2]$  in which the scope pattern  $p_1$  held and after which the property pattern  $p$  failed to hold.
- **d\_e\_bet<sub>1</sub>** includes the time interval  $[t_2, t_3]$  where  $t_2$  represents the last timestamp in which pattern  $p_1$  (the left event-boundary) held and  $t_3$  (the right event-boundary) is the first timestamp in which pattern  $p_2$  held throughout the execution trace.

## 6.3 Atoms

**Violation causes:** The violation cause **c\_not<sub>1</sub>** for the construct “**not sc**” requires **sc** to be satisfied, since for “**not sc**” to be violated, **sc** must be satisfied (see the semantics in Figure 4).

**Diagnosis:** As depicted in Figure 7, many diagnosis are associated with the violation cause **c\_not<sub>1</sub>**. Indeed, for **c\_not<sub>1</sub>** the diagnosis should explain why the violation

cause  $\mathbf{c\_not}_1$  (see Figure 6) holds, i.e., why  $sc$  is satisfied. The reasons that lead to the satisfaction of  $sc$  depend on the SB-TempPsy-DSL scope and the pattern used to define  $sc$ . When  $sc$  is satisfied, both the scope and the pattern are satisfied. Our diagnosis explains *why the pattern used to define  $sc$  holds*. For this reason, the name of the diagnosis is obtained by adding the string “ $\mathbf{d\_not}$ ” before the name of the pattern used to define  $sc$ . In the following, we explain each of the diagnoses w.r.t the pattern defining  $sc$ :

- diagnosis  $\mathbf{d\_not\_assert}$  includes a timestamp  $t$  in which one or more signals ( $s_1, s_2, \dots, s_n$ ) defined in the related property satisfy the corresponding condition  $c$  as well as the corresponding value(s) taken by each of these signals.
- diagnosis  $\mathbf{d\_not\_becomes}$  includes the first timestamp  $t$  that satisfies the property condition, as well as the value of the signal recorded at  $t$ .
- diagnosis  $\mathbf{d\_not\_spike}$  includes the first and the last records of a spike instance that occurred within the time interval  $[t_l, t_u]$ .
- diagnosis  $\mathbf{d\_not\_oscillation}$  includes the first and the last records of an oscillation instance.
- diagnosis  $\mathbf{d\_not\_rises}$  includes the first record at timestamp  $t$  in which (1) the signal defined in the property rises, reaching the property threshold  $v$ , and (2) the monotonicity constraint (if defined in the pattern) is satisfied within the time interval  $[t_l, t]$ .
- diagnosis  $\mathbf{d\_not\_overshoots}$  includes the first record at which the signal defined in the property overshoots (i.e., reaching a value that ranges between values  $v$  and  $v_1 + v_2$ ) and satisfies the monotonicity constraint, if defined in the pattern.
- diagnosis  $\mathbf{d\_not\_if-then}$  includes two time intervals delimiting where the cause pattern and the effect one of the property hold throughout the execution trace.

## 7 TD-SB-TempPsy AT WORK

In this section, we illustrate how *TD-SB-TempPsy* works by applying algorithm 1 to three example properties, each of them with different constructs.

### 7.1 Property with a single atom

Let us consider property P1, checked on the trace shown in Figure 5:

$$P1 \equiv \mathbf{after\ 7\ exists\ spike\ in\ } \beta_1 \\ \mathbf{with\ width\ } < 0.5 \mathbf{\ amplitude\ } < 90.$$

Based on the SB-TempPsy-DSL grammar in Figure 3, this property is made of a single atom of the form  $\mathbf{after\ } t\ p$ , i.e., it consists of an  $\mathbf{after}$  scope construct (delimited by an absolute time instant, parameter  $t = 7$ ) constraining a pattern  $p$  of type  $\mathbf{spike}$ .

Given the presence of only one atom in the property, algorithm 1 first determines whether the atom itself is violated by the trace (line 5). Since the trace violates the specification defined by the atom, algorithm 1 continues by computing the associated diagnosis using function TD-ATOM (algorithm 2).

Algorithm 2 relies on the auxiliary function GETVIOLATIONCAUSES, which analyzes the syntactic structure of the

atom and determines the possible violation causes associated with it. In this case, the possible violation causes are the one associated with the  $\mathbf{after}$  scope construct with an absolute boundary, i.e.,  $\mathbf{c\_a\_aft}_1$ , and the five ones associated with the  $\mathbf{spike}$  construct, i.e.,  $\mathbf{c\_spike}_i$  with  $1 \leq i \leq 5$ . This means that function GETVIOLATIONCAUSES returns the list  $vc_s = [\mathbf{c\_a\_aft}_1, \mathbf{c\_spike}_1, \mathbf{c\_spike}_2, \mathbf{c\_spike}_3, \mathbf{c\_spike}_4, \mathbf{c\_spike}_5]$ .

The algorithm continues by looping through the violation causes in  $vc_s$ , to determine the first violation cause that holds on the trace; it will then return the corresponding diagnosis. In this example, the violation cause  $\mathbf{c\_a\_aft}_1$  holds on the trace since the value of parameter  $t$  (7) is outside the time interval  $[0, 6]$ . The corresponding diagnosis  $\mathbf{d\_a\_aft}_1 = \langle [0, 6], 7 \rangle$  shows the interval  $[0, 6]$  and the absolute boundary 7.

### 7.2 Property with a single atom and negation

Let us consider property P2, checked on the trace shown in Figure 10:

$$P2 \equiv \mathbf{not\ globally\ } \beta_3 \mathbf{\ becomes\ } < 3$$

Based on the SB-TempPsy-DSL grammar in Figure 3, this property is made of a single atom of the form  $\mathbf{not\ } sc$ , where  $sc \equiv \mathbf{globally\ } p$  consists of a  $\mathbf{globally}$  scope construct constraining a pattern  $p$  of type  $\mathbf{becomes}$ .

As in the previous example, with only one atom in the property, algorithm 1 determines whether the atom itself is violated by the trace (line 5). Since the trace violates the specification defined by the atom, algorithm 1 continues by computing the associated diagnosis using function TD-ATOM (algorithm 2).

During the execution of algorithm 2, the auxiliary function GETVIOLATIONCAUSES returns the list  $vc_s = [\mathbf{c\_not}_1]$ , since, in this example, the only possible violation cause is associated with the  $\mathbf{not}$  construct.

Algorithm 2 will then compute the diagnosis corresponding to the only violation cause included in list  $vc_s$ , using the auxiliary function GETDIAGNOSIS. In this example, the violation cause  $\mathbf{c\_not}_1$  holds on the trace since there exists a time instant (timestamp 3) in which the value of signal  $\beta_3$  decreases from value 4.5 to 0.9 (at timestamp 4). The corresponding diagnosis  $\mathbf{d\_not\_becomes} = \langle 4, 0.9 \rangle$  shows the first record (at timestamp 4) in which the predicate associated with the  $\mathbf{becomes}$  pattern holds, as well as the value of the signal.

### 7.3 Property with a conjunction of two atoms

Let us consider property P3, checked on the trace shown in Figure 12

$$P3 \equiv \mathbf{globally\ } \beta_3 \mathbf{\ rises\ monotonically\ reaching\ } 3 \\ \mathbf{and\ between\ } 2 \mathbf{\ and\ } 6 \mathbf{\ assert\ } \beta_3 \leq 4$$

Based on the SB-TempPsy-DSL grammar in Figure 3, this property is made of a single clause that consists of a conjunction of two atoms  $\delta_1$  and  $\delta_2$ , where  $\delta_1 \equiv \mathbf{globally\ } \beta_3 \mathbf{\ rises\ monotonically\ reaching\ } 3$  and  $\delta_2 \equiv \mathbf{between\ } 2 \mathbf{\ and\ } 6 \mathbf{\ assert\ } \beta_3 \leq 4$ . Atom  $\delta_1$  consists of a  $\mathbf{globally}$  scope construct constraining a pattern  $p$  of type  $\mathbf{rises}$ ; atom  $\delta_2$  consists of a  $\mathbf{between}$  scope construct

(delimited by two absolute time instants, parameters  $t_1 = 2$  and  $t_2 = 7$ ) constraining a pattern  $p$  of type **assert**.

Given the presence of two atoms in the property, the loop at lines 4–6 of algorithm 1 is executed twice. More in details, algorithm 1 first determines whether atom  $\delta_1$  is violated by the trace. Since the trace violates the specification defined by the atom, algorithm 1 continues by computing the associated diagnosis using function TD-ATOM (algorithm 2). During the execution of the latter, the auxiliary function GETVIOLATIONCAUSES returns the list  $vcs = [c\_rises_1, c\_rises_2, c\_rises_3, c\_rises_4]$ , since four possible violation causes are associated with the **rises** pattern construct. Function CHECKVIOLATIONCAUSE will then determine that the first violation cause (among those in  $vcs$ ) that holds on the trace is **c\_rises<sub>3</sub>**, since signal  $\beta_3$  violates the monotonicity constraint in two time instants (at timestamp 2 with value 2 and at timestamp 3 with value 0.5). The corresponding diagnosis, computed by function GETDIAGNOSIS, is **d\_rises<sub>3</sub>** =  $\langle\langle 2, 2 \rangle, \langle 3, 0.5 \rangle\rangle$ , consisting of the tuples (each with a timestamp and the corresponding signal value) that violate the monotonicity constraint.

A similar process is followed for atom  $\delta_2$ , which is also violated by the trace. In this case, function GETVIOLATIONCAUSES returns the list  $vcs = [c\_a\_bet_1, c\_assert_1]$ , since the possible violation causes are associated with the **between** scope construct and the **assert** pattern construct. The first violation cause that holds on the trace is **c\_assert<sub>1</sub>**, since signal  $\beta_3$  violates the predicate associated with the assertion at timestamp 5, when its value reaches 4.9. The corresponding diagnosis **d\_assert<sub>1</sub>** =  $\langle 5, 4.9 \rangle$  shows the timestamp and the signal value. Algorithm 1 then ends by returning the set of the diagnoses instances, containing **d\_rises<sub>3</sub>** and **d\_assert<sub>1</sub>**.

## 8 EVALUATION

Recall that, in CPSs, temporal properties are often complex, since they are typically expressed as constraints on different signal behaviors. Although we support characterizations of individual signal behaviors, these can be and are often considered together to report violations within a single property. As a result, we are interested in assessing the *applicability* of *TD-SB-TemPsy*, that is to which extent and how efficiently *TD-SB-TemPsy* is able to report diagnoses of industrial properties violated by industrial traces.

### 8.1 Implementation

We implemented *TD-SB-TemPsy* as an OCL [23] plugin for SB-TemPsy-Check [1]. The plugin contains the definitions of OCL constraints that encode the violation causes (see Figure 6) as well as OCL functions that compute the diagnoses (see Figures 7–8) associated with the violation causes. The full OCL encoding is available at <https://figshare.com/s/50f355f84a28fcbcc153>.

### 8.2 Dataset

To investigate the applicability of *TD-SB-TemPsy*, we considered 361 traces provided by our industrial partner; each of these traces logs in-orbit operations of a satellite. The number of records in the traces ranges from 25 358 to 9 328 178

( $avg = 438\,224$ ,  $StdDev \approx 596\,505$ ), and the recording interval ranges from 25 min to 23 h.29 min ( $avg = 6\text{ h.}38\text{ min}$ ,  $StdDev = 7\text{ h.}5\text{ min}$ ).

We considered 98 properties defined with our industrial partner and expressed in SB-TemPsy-DSL. The number of occurrences of each scope and pattern construct of SB-TemPsy-DSL in the properties is the following. For scopes: **globally** 73, **before** 1, **after** 8, **at** 3, **between** 15; for patterns: **assert** 111, **becomes** 13, **spike** 5, **oscillation** 23, **rises** 3, **falls** 7, **overshoots** 4, **undershoots** 4, **if-then** 23. All the listed scopes and pattern constructs are used in the definition of at least one property; we remark that none of the properties used the **not** sc construct for defining atoms.

We considered  $361 \times 98 = 35\,378$  trace-property combinations, each obtained from one of the 361 traces and one of the 98 properties. We removed 13 426 trace-property combinations for which the trace did not log (in any of its records) any variable used in the property and therefore did not enable the verification of its satisfaction. Then, we iteratively considered each of the remaining 21 952 trace-property combinations. Due to the sampling strategy used by our industrial partner, two records of the same trace may log different variables, i.e., a value may not be present in every record for some of the variables. Therefore, to ensure that the traces have the format described in section 2, we proceeded as follows. For each trace-property combination, we (a) removed entirely from the trace all the records that only contain variable values that do not refer to any of the variables used in the considered property, since these records do not affect its satisfaction; (b) removed, from each of the remaining records, the values of the variables that were not used in the property, while preserving the rest of the record; (c) generated missing values for the remaining variables by using various interpolation functions [24]. We considered different interpolation functions depending on the type of the signal, as commonly done in the literature (e.g., [2]).

Then, we analyzed each of the resulting 21 952 trace-property combinations. Since *TD-SB-TemPsy* aims to support engineers in detecting the source of property violations, we are interested in selecting the trace-property combinations that lead to such violations. We executed SB-TemPsy-Check by setting a timeout of 1 min, thus enabling us to consider all the trace-property combinations in approximately  $1\text{ min} \times 21952 = 15$  days of computation. Out of the 21 952 trace-property combinations, 2328 of them timed out ( $\approx 10.60\%$ ). Among the remaining 19 624 ( $\approx 89.40\%$ ) trace-property combinations that did not timeout, 14 940 combinations represent traces that violate a property (76.13%). Though this may appear surprising at first, some of the properties only refer to specific phases of the satellite life cycle (e.g., satellite launch, deployment). We nevertheless checked these properties by considering all the traces provided by our industrial partner, including the ones that refer to the actual regular operations of the satellite. These trace-property combinations naturally led to a property

violation<sup>5</sup>.

Our final dataset contains 14 940 trace-property combinations leading to a property violation. In this dataset, the number of records in the traces ranges from 1 to 11 901 ( $avg \approx 1032$ ,  $StdDev \approx 1471$ ), the recording interval ranges from 0s, for traces with a single record, to 23 h.28 min ( $avg = 4\text{h}.51\text{min}$ ,  $StdDev = 6\text{h}.24\text{min}$ ). Notice that the number of records and the recording intervals of the traces of the final dataset are significantly smaller than those observed for the original traces. This is due to the fact that, for each trace-property combination, we removed from the trace all the records that only contained variable values that did not refer to any of the variables of the considered property (see step (a) above).

We remark that, to the best of our knowledge, there is no public dataset containing traces and properties suitable for works in the area of monitoring or diagnostics for signal-based temporal properties. For example, existing works in this area, that use different specification languages (e.g., STL [10], [13] and HLS [2]), have not released their traces and properties. Moreover, the lack of standardized benchmarks in the field of runtime verification is a well-known issue [25], hindered by the diversity of the tools' specification languages [26]. Existing specification-based generators for synthesized traces target a particular specification language, such as MFODL [27], MLTL [28], and MTL [29]. No trace generator exists for SB-TemPsy-DSL or for other languages for signal-based properties (like STL and HLS).

### 8.3 Applicability

We assessed the applicability of *TD-SB-TemPsy* by considering the 14940 trace-property combinations in our dataset. Applicability entails the capacity to report diagnoses within reasonable time.

We remark that we could not perform a comparison between *TD-SB-TemPsy* and state-of-the-art tools, for a number of reasons. First, some alternative approaches [14], [15], [16] do not support signal-based temporal properties, thus making any comparison impossible. The only alternative that supports signal-based properties is AMT2.0 [10], [13]. However, the tool is no longer publicly available<sup>6</sup> and its successor *rtamt* [30] has dropped support for diagnostics capabilities, rendering impossible any experimental comparison.

#### Methodology.

We executed *TD-SB-TemPsy* on each trace-property combination in the dataset, with a timeout of 1 min, leading to approximately  $1\text{min} \times 14940 = 10$  days of computation. For each execution, we recorded whether *TD-SB-TemPsy* finished within the timeout and the diagnoses (if any) it yielded. To assess the applicability of *TD-SB-TemPsy*, we analyzed the number of combinations in which *TD-SB-TemPsy* finished within the timeout and whether it yielded a diagnosis, i.e., whether at least one violation cause was applicable. We conducted our evaluation on a high-performance

5. A property that does not refer to the regular operations of the satellite is expected to be violated if checked on a trace recording such regular operations.

6. <https://www-verimag.imag.fr/AMT-2-0.html>

Table 1

Number (#N) of diagnosis instances generated by *TD-SB-TemPsy* for each scope and pattern construct of SB-TemPsy-DSL (as used in the properties in our datasets).

Type	Construct	#N	Construct	#N	Construct	#N
main dataset						
Scope	<b>globally</b>	0	<b>before</b>	294	<b>after</b>	2640
	<b>at</b>	1002	<b>between</b>	660		
Pattern	<b>assert</b>	7098	<b>becomes</b>	0	<b>spike</b>	321
	<b>oscillation</b>	460	<b>rises</b>	0	<b>falls</b>	0
	<b>overshoots</b>	0	<b>undershoots</b>	0	<b>if-then</b>	11
MD1 dataset						
Pattern	<b>becomes</b>	656	<b>overshoots</b>	942	<b>undershoots</b>	940
MD2 dataset						
Pattern	<b>rises</b>	90	<b>falls</b>	90		

computing platform, using nodes equipped with Dell C6320 units (2 Xeon E5-2680v4@2.4 GHz, 128 GB).

#### Results.

*TD-SB-TemPsy* finished within the timeout for  $\approx 80.66\%$  of the combinations (12 051 out of 14 940).

For the remaining 2889 combinations that *timed out*,  $\approx 9.48\%$  of these combinations (274 out of 2889) come from properties using the **if-then** construct,  $\approx 76.71\%$  of the combinations (2216 out of 2889) come from properties using the event scope constructs, and  $\approx 13.81\%$  of the combinations (399 out of 2889) come from properties that used the **or** and **and** operators to combine properties and clauses defined using the aforementioned constructs. For these combinations, the computational overhead to compute the diagnosis led to timeouts. Note that, in practice, engineers are likely to use larger timeouts than the one selected here, which is due to experimental constraints, and, therefore, we expect the percentage of combinations that time out to decrease.

For the 12 051 trace-property combinations that *finished within the timeout*, *TD-SB-TemPsy* always returned a diagnosis. We recall that a diagnosis is made by one or more diagnosis instances that are generated by *TD-SB-TemPsy* for the different atoms of the formula (see Section 4). These instances describe why the scope and pattern constructs of SB-TemPsy-DSL used for the definitions of the atom are violated by a trace. *TD-SB-TemPsy* produced one diagnosis instance for each atom of the formula (corresponding to the input property) for 94.38% of the combinations (11 374 out of 12 051). For the remaining 5.62% of the combinations (677 out of 12 051), some atoms of the formula did not lead to any diagnosis instance. In total, the 12 051 combinations returned 12 486 diagnosis instances.

The top part of Table 1 shows the number of diagnosis instances (column #N) computed by *TD-SB-TemPsy* for each scope and pattern construct of SB-TemPsy-DSL (as used in the properties in our main dataset). These results suggest that a relatively high percentage of the diagnosis instances ( $1002 + 294 + 660 + 2640 = 4596$  out of 12 486,  $\approx 36.81\%$ ) are related to scope constructs. Indeed, since we considered all the possible trace-property combinations in our dataset, there are many combinations for which the time instant

values used to define the scope operators exceeded the maximum timestamp recorded in the trace. The remaining  $\approx 63.19\%$  of the diagnosis instances ( $7098+460+321+11 = 7890$  out of  $12\,486$ ) are related to patterns constructs. *TD-SB-TemPsy* returned diagnosis instances for the **assert**, **spike**, **oscillation**, and **if-then** constructs, though with different prevalence. *TD-SB-TemPsy* did not report any diagnosis instances for the **becomes**, **rises**, **falls**, **overshoots**, and **undershoots** constructs. We further analyzed the properties containing these constructs and noticed that, in all these cases, *TD-SB-TemPsy* detected a violation of the corresponding scope. In such cases, the diagnosis instances returned by *TD-SB-TemPsy* are only related to the scope constructs.

To guarantee a complete applicability assessment of *TD-SB-TemPsy*, covering all SB-TemPsy-DSL constructs, we built two additional datasets (MD1 and MD2), derived from the main one, using the following strategies:

**MD1 (replacing the property scope).** We considered all the 2562 trace-property combinations where the properties are defined using only one single pattern of type **becomes**, **overshoots**, or **undershoots** within a scope operator. We changed the scope of the patterns to **globally** in order to avoid any scope violations, thus making the detection of violations of these property patterns possible. As a result, we obtained 2562 additional trace-property combinations which constitute the MD1 dataset.

**MD2 (changing the pattern definition).** The patterns **rises** and **falls** were not used in any property containing only one single pattern, but were always used within the **if-then** construct. Therefore, we considered the 180 trace-property combinations where the properties contained the **rises** and **falls** patterns and extracted from the **if-then** construct the subproperties that were using these patterns. This led to 180 additional trace-property combinations, which constitute the MD2 dataset.

We executed *TD-SB-TemPsy* on the MD1 and MD2 datasets with a timeout of 1 min. In the case of MD1, *TD-SB-TemPsy* yielded diagnosis instances for  $\approx 99.06\%$  of the combinations (2538 out of 2562), with no timeout; the distribution of these instances is shown in the middle part of Table 1. For MD2, *TD-SB-TemPsy* yielded diagnosis instances for all 180 combinations; the distribution of these instances is shown in the bottom part of Table 1.

In conclusion, the results showed that *TD-SB-TemPsy* was widely applicable in the context of an industrial case study. Indeed, when considering the main dataset as well as MD1 and MD2, *TD-SB-TemPsy* was able to finish within the small timeout of 1 min for  $12\,051 + 2562 + 180 = 14\,793$  out of  $14\,940 + 2562 + 180 = 17\,682$  ( $\approx 83.66\%$ ) of the trace-property combinations in our dataset, returning a diagnosis for  $12\,051 + 2538 + 180 = 14\,769$  combinations ( $\approx 99.84\%$  of the cases). These results suggest that, in practice, our set of violation causes provide sufficient coverage of observed violations.

## 8.4 Threats to Validity

In terms of *internal validity*, the choice of a timeout of 1 min, justified by the high computational time for the experiments (15 days), led to a number of trace-property combinations

for which *TD-SB-TemPsy* did not finish its execution. Considering a larger timeout would further increase the applicability of *TD-SB-TemPsy*.

In terms of *external validity*, the trace-property combinations in our dataset may be a threat for the generalization of our results, as other datasets may differ in terms of (a) the constructs used for expressing the properties, (b) the type of property violations. We mitigated this threat by selecting an industrial case study in the satellite domain that is representative of complex CPS, with large traces and many complex properties elicited with experts. Further, we modified scopes and patterns in our case study properties to expand our analysis such as to consider more trace-property combinations.

Regarding *conclusion validity*, the trace-property combinations in our dataset did not trigger all the 34 violation causes in our catalogue (see Figure 6). More in details, trace-property combinations from the main dataset cover 9 out of the 34 violation causes. Including additional datasets (MD1 and MD2), covered violation causes reach 17 out of 34 (8 new ones). These 8 new covered violations causes are distributed as follows: 2 **becomes**, 2 **rises** (and its dual **falls**) and 4 **overshoots** (and its dual **undershoots**).

## 8.5 Data Availability

We cannot publicly release the traces and properties used in the experiments because they are subject to a non-disclosure agreement. The raw output of *TD-SB-TemPsy* and the script used for the analysis of the evaluation data are available at <https://figshare.com/s/50f355f84a28fcbcc153>; we are going to make this dataset public upon acceptance. Also upon acceptance, we are going to release *TD-SB-TemPsy* under a FOSS license.

## 9 RELATED WORK

The problem of enriching Boolean verification verdicts with additional information that supports reasoning on the causes of such verdicts has been widely studied in the literature. This section discusses related work in the trace-checking and model-checking areas. We included the latter since a trace can be seen as a model made by a sequence of consecutive states, each representing one trace record, with transitions connecting the consecutive records.

In the *trace-checking* area, there are two main strategies (see Section 1) that aim to provide additional information on the causes of a property violation: (i) isolating slices of the traces that explain the property violation (e.g., [10], [11], [12], [13]); and (ii) checking whether the traces show common behaviors that lead to the property violation (e.g., [14], [15], [16]). The first strategy produces large explanations for complex properties since the size of the explanation increases with the number of operators of the formula expressing the property of interest. Existing approaches based on the second strategy do not support complex signal-based temporal properties (as the ones considered in this work) and are not complemented by a precise methodology that describes how to add new causes that support more complex properties. Therefore, in this work we have proposed a novel, language-agnostic methodology for defining *violation*

causes and diagnoses, and applied it in the context of signal-based temporal properties expressed in SB-TemPsy-DSL.

In the *model-checking* area, some approaches (e.g., [31], [32], [33], [34], [35], [36], [37], [38], [39], [40]) extract information from the model (e.g., model slices) to explain the model checking verdict. Typically, these approaches have limited scalability and therefore are not easily applicable to the trace-checking scenario. *TD-SB-TemPsy* relies on a conceptually different technique, which leverages violation causes and diagnoses to explain trace checking verdicts. Moreover, its implementation uses existing technologies that showed encouraging scalability results in previous works; our evaluation confirms the applicability of our solution. Other approaches (e.g., [41], [42], [43], [44], [45], [46], [47]) rely on deductive reasoning techniques to explain model checking verdicts. Different from the approach proposed in this work, they usually provide an exhaustive explanation for a verdict by considering some initial assertions (e.g., simple conditions on the values assumed by the variables in the states of the model) and examining how logical operators can be applied to reach a specific logical conclusion. However, the proofs produced by deductive reasoning approaches are usually difficult to understand for non-experts. Besides, their size significantly grows with the size of the model to analyze [48]. Therefore, when the model represents a trace, which is typically large in practice (i.e., because of a large number of records), the generated proofs are likely to be extremely large and difficult to understand by engineers.

## 10 CONCLUSION

In this paper, we proposed *TD-SB-TemPsy*, a trace-diagnostic approach for signal-based temporal properties, based on violation causes and diagnoses. We defined a methodology for defining violation causes and diagnoses that provides formal soundness guarantees. We proposed a catalog of 34 violation causes, each associated with one diagnosis, for properties expressed in SB-TemPsy-DSL. We evaluated *TD-SB-TemPsy* by assessing its applicability on a large set of trace-property combinations from an industrial case study in the satellite domain. *TD-SB-TemPsy* finished within the stringent timeout of 1 min for  $\approx 83.66\%$  of these combinations and provided a diagnosis for  $\approx 99.84\%$  of these cases. In practice, outside of experimental settings, longer timeouts can be considered.

In the future, we plan to perform a large-scale, systematic evaluation to assess (a) the scalability of *TD-SB-TemPsy* with respect to the trace size and (b) its applicability when dealing with different violation causes. This evaluation requires the use of synthesized traces, which enable varying the trace size and controlling the causes of property violations. In addition, we intend to conduct a user study to assess the usefulness of the diagnoses provided by *TD-SB-TemPsy*, for example in the context of fault localization. Furthermore, we foresee the application of our methodology for defining violation causes to other pattern-based specification languages, to corroborate our language-agnosticism claim through concrete examples.
