Abstract

We discuss the asymptotic analysis of parameter estimation for Ewens–Pitman Partition with parameter \((\alpha, \theta)\) when \(0 < \alpha < 1\) and \(\theta > -\alpha\). For the following cases: \(\alpha\) unknown \(\theta\) known, \(\alpha\) known \(\theta\) unknown, and both \(\alpha\) and \(\theta\) unknown, we derive the asymptotic law of Maximum Likelihood Estimator (MLE). We show that the MLE for \(\theta\) does not have consistency, whereas the MLE for \(\alpha\) is \(n^{\alpha/2}\)-consistent and asymptotically mixed normal. Furthermore, we propose a confidence interval for \(\alpha\) from a mixing convergence of the MLE. In contrast, we propose Quasi-Maximum Likelihood Estimator (QMLE) as an estimator of \(\alpha\) with \(\theta\) unknown, which has the same asymptotic mixed normality as the MLE. We also derive the asymptotic error of MLE and QMLE. Finally, we compare them in terms of efficiency and coverage in numerical experiments.

1 Introduction

For a given positive integer \(n \in \mathbb{N}\), a partition of \([n] := \{1, 2, \ldots, n\}\) into \(k\) blocks is an unordered collection of non-empty disjoint sets \(\{U_1, U_2, \ldots, U_k\}\) whose union is \([n]\). We define \(P_n^k\) as the set of all partitions of \(n\) into \(k\) blocks and let \(P_n := \cup_{k=1}^n P_n^k\), the set of all partitions of \([n]\). Then, Ewens–Pitman partition with parameter \((\alpha, \theta)\) is the distribution on \(P_n\) with the following density:

\[
\forall \Pi_n \in P_n, \Pr(\Pi_n = \{U_1, \ldots, U_{K_n}\}) = \prod_{i=1}^{K_n-1} \frac{(\theta + i\alpha)}{(\theta + i)} \prod_{j=2}^{n} \left \{ \prod_{i=1}^{j-1} (-\alpha + i) \right \}^{S_{n,j}}, \quad (1.1)
\]

where \(S_{n,j} := \sum_{i=1}^{K_n} \mathbb{I}\{|U_i| = j\}\) is the number of blocks of size \(j\). Note that (1.1) is referred to as Ewens–Pitman sampling formula. Considering \(\sum_{j=1}^{n} S_{n,j} = K_n\) and \(\sum_{j=1}^{n} j S_{n,j} = n\), \((S_{n,j})_{j=1}^{n}\), which is described as ‘frequency of frequencies’ by [9], is sufficient statistics for \((\alpha, \theta)\). Here, the parameter space is divided into the following three cases: \(\{\alpha = 0, \theta > 0\}\), \(\{\alpha < 0, \exists k \in \mathbb{N}\text{ such that }\theta =\)

Figure 1: Illustration of the asymptotics of Ewens–Pitman partition when $0 < \alpha < 1, \theta > -\alpha$.

$-k\alpha$, and $\{0 < \alpha < 1, \theta > -\alpha\}$, each of which corresponds to a different asymptotic law. In this study, we focus on the third case (see Section 2.3 for the other cases), in which the following almost sure convergence holds (see Figure 1 for the illustration):

(i) $K_n/n^\alpha \to M_{\alpha\theta}$, (ii) $\forall j \in \mathbb{N}, \frac{S_{n,j}}{K_n} \to p_\alpha(j) := \frac{\alpha \prod_{i=1}^{j-1} (i-\alpha)}{j!}$,

where $M_{\alpha\theta}$ follows generalized Mittag-Leffler distribution $(\alpha, \theta)$, denoted by GMtLf($\alpha, \theta$) (see Section 2.2 for the definition), and the discrete distribution on $\mathbb{N}$ with density $p_\alpha(j)$ is referred to as Sibuya distribution (see Section 2.1).

Ewens–Pitman partition arises in many fields such as network analysis [4], nonparametric Bayesian inference [5, 2], microdata disclosure [11], and ecology [17], as well as forensic [3]. In those studies, estimation of $(\alpha, \theta)$ matters; especially that of $\alpha$ is of more interest considering it controls the asymptotic orders as shown in Figure 1. However, previous research on the estimation of $\alpha$ is limited. It is clear from $K_n/n^\alpha \to M_{\alpha\theta}$ by (i) of (1.2) that the naive estimator $\hat{\alpha}_n := \log K_n/\log n$ is log-$n$-consistent. Note that it is not rate optimal owing to the information loss from the sufficient statistics $(S_{n,j})_{j=1}^n$ to $K_n = \sum_{j=1}^n S_{n,j}$. Conversely, except for the naive estimator, no consistent estimators for $\alpha$ have been found to date, let alone rate-optimal estimators. In fact, [1] worked on the analysis of Maximum Likelihood Estimator (MLE), which is a natural candidate for the rate-optimal estimators. However, the asymptotics of the MLE for $\alpha$ has been an open problem to the best of our knowledge, whereas [4] confirmed numerically that it was consistent.

This study investigates the asymptotic law of the MLE for the parameter $(\alpha, \theta)$ when $0 < \alpha < 1$ and $\theta > -\alpha$. First, we derive the leading term of Fisher information of (1.1) as follows: (Proposition 3.3)

$I_{\alpha\theta}^{(n)} \sim n^\alpha \mathbb{E}[M_{\alpha\theta}] I(\alpha) = O(n^\alpha), \quad I_{\theta}^{(n)} \sim \alpha^{-1} \log n = O(\log n), \quad I_{\theta\theta}^{(n)} \to f_\alpha'(\theta/\alpha) = O(1)$.

(1.3)

where $M_{\alpha\theta} \sim$ GMtLf($\alpha, \theta$) and $I(\alpha)$ is Fisher information of Sibuya distribution expressed by Proposition 3.1. Recall that these distributions appeared in (1.2). Furthermore, $f_\alpha'$ is the derivative of the function $f_\alpha : (-1, \infty) \to \mathbb{R}$ defined by

$f_\alpha : z \mapsto \psi(1+z) - \alpha \psi(1+\alpha z)$,

where $\psi(z) = \Gamma'(z)/\Gamma(z)$ is the digamma function. Note that $f_\alpha$ is bijective with $f_\alpha'(z) > 0$ and $f_\alpha''(z) < 0$ (see Lemma 3.2). (1.3) implies that there is no identifiability of $\theta$ (see Remark 2.2 for the mutual absolute continuity with respect to $\theta$) and the optimal convergence rate of estimators of $\alpha$ is at most $n^{\alpha/2}$, which is smaller than the typical rate $\sqrt{n}$ in I.I.D. cases owing to $0 < \alpha < 1$. Moreover, $\alpha$ and $\theta$ are asymptotically orthogonal, i.e., information about $\theta$ has less effect on the estimation of $\alpha$ as $n$ increases (see the left side of Figure 2).
Next, let us define $\hat{\alpha}_{n,\theta}$ as the MLE for $\alpha$ when $\theta$ is known. Then, $\hat{\alpha}_{n,\theta}$ is consistent, and the following stable convergence holds: (Theorem 3.9)

$$\sqrt{n} I(\alpha) \cdot (\hat{\alpha}_{n,\theta} - \alpha) \rightarrow N/\sqrt{M_{\alpha \theta}},$$

where $N \sim \mathcal{N}(0,1)$ is independent of the $\sigma$-field $\mathcal{F}_{\infty} := \sigma(\bigcup_{n=1}^{\infty} \mathcal{F}_n)$ with $\mathcal{F}_n$ defined as the $\sigma$-field generated by the partition of $n$ balls, and $M_{\alpha \theta} \sim \text{GMtLf}(\alpha, \theta)$ is $\mathcal{F}_{\infty}$-measurable.

Note that (i) of (1.2) and (1.5) with an extended Slutsky’s lemma for stable convergence (Lemma 2.3) result in

$$\sqrt{K_n} I(\alpha) \cdot (\hat{\alpha}_{n,\theta} - \alpha) \rightarrow N \mathcal{F}_{\infty}$-

mixing,

which implies that $[\hat{\alpha}_n \pm 1.96/\sqrt{I(\hat{\alpha}_n)K_n}]$ is a 95% confidence interval for $\alpha$ (see Corollary 3.9.1).

Intuitively speaking, $K_n$ corresponds to the sample size $n$ in typical I.I.D. cases. In contrast, (1.3) and (1.5) imply

$$\sqrt{n} I_n(\alpha) \cdot (\hat{\alpha}_{n,\theta} - \alpha) \rightarrow \sqrt{\mathbb{E}[M_{\alpha \theta}]} \cdot N \mathcal{F}_{\infty},$$

where the limit law is mixed normal by the randomness of $M_{\alpha \theta}$. Interestingly, the degree of mixing is weakened when $\theta$ is large or $\alpha$ is small (see Proposition 3.10 for details).

Finally, we consider the setting of $\alpha$ and $\theta$ unknown, where we define Quasi-Maximum likelihood estimator (QMLE) $\hat{\alpha}_{n,\theta^*}$ as the maximizer of the quasi-likelihood with respect to $\alpha$ with the unknown $\theta$ being replaced by users with an arbitrary $\theta^*$ (see Figure 2 for the illustration). We also define Simultaneous Maximum Likelihood Estimator (SMLE) $(\hat{\alpha}_n, \hat{\theta}_n)$ as the maximizer of the likelihood with respect to $(\alpha, \theta)$. Then, (1.5) also holds for $\hat{\alpha}_{n,\theta^*}$ and $\hat{\alpha}_n$. In particular, their errors to $\hat{\alpha}_{n,\theta}$ (MLE of $\alpha$ with $\theta$ known) converge in probability as follows: (Theorem 3.18, 3.23)

(i) $n^\alpha \log n (\hat{\alpha}_{n,\theta^*} - \hat{\alpha}_{n,\theta}) \rightarrow -\frac{\theta^* - \theta}{\alpha I(\alpha) M_{\alpha \theta}},$

(ii) $n^\alpha \log n (\hat{\alpha}_n - \hat{\alpha}_{n,\theta}) \rightarrow -\frac{\alpha f^{-1}_\alpha(\log M_{\alpha \theta}) - \theta}{\alpha I(\alpha) M_{\alpha \theta}},$

where $f^{-1}_\alpha$ is the inverse of the bijective function $f_\alpha$ defined by (1.4). Furthermore, we verify numerically that the law $\alpha f^{-1}_\alpha(\log M_{\alpha \theta})$ in (ii) is distributed around $\theta$ (see Remark 3.14). At first, the difference of (i) and (ii) seems negligible; however, we confirm in terms of coverage and efficiency that $\hat{\alpha}_{n,\theta^*}$ is significantly worse than $\hat{\alpha}_{n,\theta}$ when “plug-in error” $|\theta^* - \theta|$ is large whereas $\hat{\alpha}_n$ is about the same as $\hat{\alpha}_{n,\theta}$.

Outline of this paper: Section 2 is preliminaries for the following sections. Section 3.1 gives Fisher information of Sibuya distribution and Ewens–Pitman partition. Section 3.2, 3.3, and 3.4 correspond to the case of $\alpha$ unknown with $\theta$ known, $\theta$ unknown with $\alpha$ known, and both $\alpha$ and $\theta$ unknown, respectively. In Section 4, we compare MLE, QMLE, and SMLE numerically.
2 Preliminaries

2.1 Sibuya distribution

We denote the set of all positive integers by \( \mathbb{N} \). Then, for each \( 0 < \alpha < 1 \), Sibuya distribution with parameter \( \alpha \), which first appeared in [16], is a discrete distribution on \( \mathbb{N} \) with its probability mass function \( p_\alpha(j) \) defined as:

\[
\forall j \in \mathbb{N}, \quad p_\alpha(j) := \frac{\alpha}{j!} \prod_{i=1}^{j-1} (i - \alpha).
\]

Stirling’s formula \( \Gamma(z) \sim \sqrt{2\pi} \left( \frac{z}{e} \right)^z \) implies \( p_\alpha(j) \sim \frac{\alpha}{\Gamma(1 - \alpha)} \cdot j^{-1} \), and hence, it is heavy-tailed. Note that the Sibuya distribution arises in the extreme value theory. See [15, 13] for more details.

2.2 Mittag-Leffler distribution

For each \( 0 < \alpha < 1 \), Mittag-Leffler distribution \( (\alpha) \) is a probability distribution on \((0, \infty)\) with its density \( g_\alpha(x) \) characterized by

\[
\forall p > -1, \quad \int_0^\infty x^p g_\alpha(x) \, dx = \frac{\Gamma(p+1)}{\Gamma(p\alpha+1)}. \tag{2.1}
\]

For each \( \theta > -\alpha \), Generalized Mittag-Leffler distribution \( (\alpha, \theta) \), denoted by \( \text{GMtLf}(\alpha, \theta) \), has the density \( g_{\alpha,\theta}(x) \) defined by

\[
g_{\alpha,\theta}(x) := \frac{\Gamma(\theta+1)}{\Gamma(\theta/\alpha+1)} x^{\theta/\alpha} g_\alpha(x). \tag{2.2}
\]

Note that \( \text{GMtLf}(\alpha, \theta = 0) \) equals the Mittag-Leffler distribution \( (\alpha) \). Herein, we denote random variables following \( \text{GMtLf}(\alpha, \theta) \) by \( M_{\alpha\theta} \). From (2.1) and (2.2), its moment can be written as:

\[
\forall p > -(1 + \theta/\alpha), \quad E[(M_{\alpha\theta})^p] = \frac{\Gamma(\theta+1)}{\Gamma(\theta/\alpha+1)} \frac{\Gamma(\theta/\alpha + p + 1)}{\Gamma(\theta+pa+1)}. \tag{2.3}
\]

See [14, p. 10] for the definition based on subordinators.

2.3 Asymptotics of Ewens–Pitman Partition

Ewens–Pitman Partition can be described as a stochastic process that randomly and sequentially assigns balls into urns as follows: (i) The first ball belongs to urn \( U_1 \) with probability one. (ii) Suppose \( n \geq 1 \) balls are partitioned into \( K_n \) occupied urns \( \{U_1, U_2, \ldots U_{K_n}\} \). Then, the \((n+1)\)th ball belongs to

- Urn \( U_i \) with probability \((|U_i| - \alpha)/(\theta + n)\) \((|U_i| \) is the number of balls in \( U_i \)).
- A new urn with probability \((\theta + K_n\alpha)/(\theta + n)\).

It easily follows by induction that the probability of the resulting random partition \( \{U_1, U_2, \ldots U_{K_n}\} \) coincides with (1.1). Recall that Ewens–Pitman Partition has three parameter spaces: (i) \( \alpha = 0, \theta > 0 \), (ii) \( \alpha < 0, \exists k \in \mathbb{N} \) s.t. \( \theta = -k\alpha \), and (iii) \( 0 < \alpha < 1, \theta > -\alpha \). Herein, we discuss the parameter dependency of its asymptotics.

(i) \( \alpha = 0, \theta > 0 \): It is referred to as Ewens Partition. Substituting \( \alpha = 0 \) into (1.1), we see that the density is proportional to \( \theta^{K_n}/(\prod_{i=0}^{n-1} (\theta + i)) \), and hence \( K_n \) is the sufficient statistic for \( \theta \). Herein, we
define \( \theta^*_n := K_n / \log n \). Considering \( K_n \) is expressed as the sum of independent random variables \((\zeta_i)_{i=1}^\infty\) as \( K_n = \sum_{i=1}^n \zeta_i, \zeta_i \sim \text{Bernoulli}(\theta / (\theta + i - 1)) \) by the sequential definition, [12] proved \( \theta^*_n \to \theta \) (a.s.). Moreover, it quickly follows from the Lindeberg-Feller theorem (see, for example, [6, p. 128]) that \( (\theta^{-1} \log n)^{1/2}(\theta^*_n - \theta) \to \mathcal{N}(0,1) \) weakly. Furthermore, its Fisher information \( I^{(n)}_{\theta\theta} \) is calculated by \( I^{(n)}_{\theta\theta} = \mathbb{E}[K_n] \theta^{-2} + \sum_{i=0}^{n-1} (\theta + i)^{-2} \sim \theta^{-1} \log n \), from which we see that \( \theta^*_n \) is asymptotically efficient. In contrast, MLE for \( \theta \) is also asymptotically normal with the same asymptotic variance as \( \theta^*_n \). See [1, p. 80] for the MLE of \( \theta \) and [19] for the case of \( \theta \) increasing with \( n \).

(ii) \( \alpha < 0, \exists k \in \mathbb{N} \) s.t. \( \theta = -k\alpha \): In this case, the number of occupied urns \( K_n \) is finite, i.e., \( K_n \to k \) (a.s.), considering the probability of observing a new urn is proportional to \((-\alpha)(k - K_n)\), which is strictly positive until \( K_n \) reaches \( k \).

(iii) \( 0 < \alpha < 1, \theta > -\alpha \): In this case, the following asymptotics hold.

**Lemma 2.1.** Suppose \((\alpha, \theta)\) satisfies \( 0 < \alpha < 1, \theta > -\alpha \). Let \( S_{n,j} \) be the number of urns of size \( j \) and \( K_n = \sum_{j \geq 1} S_{n,j} \) the number of urns. Then, we have

(A) \( K_n / n^\alpha \to M_{a,\theta} \) a.s. and in \( p \)-th mean for all \( p > 0 \), where \( M_{a,\theta} \sim \text{GMLf}(\alpha, \theta) \).

(B) \( S_{n,j} / K_n \to P_\alpha(j) \) a.s. for all \( j \in \mathbb{N} \), where \( P_\alpha(j) \) is the density of Sibuya distribution.

**Sketch of proof.** Let \( \mathbb{P}_{\alpha,\theta} \) denote the law of Ewens–Pitman Partition with parameter \((\alpha, \theta)\). Then, (A) can be shown by applying the martingale convergence theorem to the likelihood ratio \( d\mathbb{P}_{\alpha,\theta} / d\mathbb{P}_{\alpha,0} \) under \( \mathbb{P}_{\alpha,0} \), where \( F_n \) is the \( \sigma \)-field generated by the partition of \( n \) balls. As for (B), Kingman’s representation theorem (see, for example, [7, p. 440]) implies that Ewens–Pitman Partition can be expressed as the tied observation of conditional i.i.d. samples from Poisson–Dirichlet distribution. Therefore, we can analyze \( S_{n,j} / K_n \) in the setting of classical occupancy problems. See [14, Theorem 3.8] for the detail of the proof of (A) and [14, Lemma 3.11] and [8] for (B).

**Remark 2.2** ([14, p. 71]). We can show the absolute mutual continuity of \( \mathbb{P}_{a,\theta} \) and \( \mathbb{P}_{a,0} \) for each \( \theta(> -\alpha) \) as a byproduct of the proof of (A). Precisely, the Radon-Nikodym density is given as:

\[
\frac{d\mathbb{P}_{\alpha,\theta}}{d\mathbb{P}_{\alpha,0}} = \frac{\Gamma(\theta + 1)}{\Gamma(\theta/\alpha + 1)} M^{\theta/\alpha}_{a,0} \text{-a.s.,}
\]

where \( M_{\alpha} \) is the almost sure limit of \( n^{-\alpha} K_n \) under \( \mathbb{P}_{\alpha,0} \). This is consistent with the fact that Fisher information about \( \theta \) is bounded (see Proposition 3.3).

### 2.4 Stable convergence

Herein, we introduce stable convergence and its application to the Martingale central limit theorem, which will appear in the proof of the asymptotic mixed normality in Section 3. Let \((\Omega, \mathcal{F}, P)\) denote a probability space and let \( X \) be a separable metrizable topological space equipped with its Borel \( \sigma \)-field \( \mathcal{B}(X) \). For a probability space \((\Omega, \mathcal{F}, P)\), let \( L^p(\Omega, \mathcal{F}, P) = \mathcal{L}^p(P) \) denote the set of \( \mathcal{F} \)-measurable functions that satisfy \( \int |f|^p dP < +\infty \) for a real number \( p > 0 \), and we denote the set of continuous bounded functions on \( X \) by \( C_b(X) \).

**Definition 2.1.** Let \( \mathcal{G} \subset \mathcal{F} \) be a sub \( \sigma \)-field. Then, a sequence of \((\mathcal{X}, \mathcal{B}(\mathcal{X}))\)-valued random variables \((X_n)_{n \geq 1}\) is said to converge \( \mathcal{G} \)-stably to \( X \), written by \( X_n \to X \) \( \mathcal{G} \)-stably, if

\[
\forall f \in \mathcal{L}^1(P), \forall h \in C_b(X), \lim_{n \to \infty} \mathbb{E}[f \mathbb{E}[h(X_n)|\mathcal{G}]] = \mathbb{E}[f \mathbb{E}[h(X)|\mathcal{G}]]. \tag{2.4}
\]

If \( X \) is independent of \( \mathcal{G} \), \((X_n)_{n \geq 1}\) is said to converge \( \mathcal{G} \)-mixing, denoted by \( X_n \to X \) \( \mathcal{G} \)-mixing.

By putting \( f = 1 \) in (2.4), we can see that stable convergence implies weak convergence. In contrast, if \( \mathcal{G} = \{0, \Omega\} \), \( \mathbb{E}[f \mathbb{E}[h(X_n)|\mathcal{G}]] = \int f \, dP \cdot \mathbb{E}[h(X_n)] \) holds for all \( f \in \mathcal{L}^1(P) \), and hence, \( X_n \to X \) \( \mathcal{G} \)-stably coincides with \( X_n \to X \) weakly.
Lemma 2.3 ([10, p. 34]). For $(X, B(X))$, $(Y, B(Y))$, a pair of separable metrizable spaces with metric $d$, let $(X_n)_{n \geq 1}$ be a sequence of $(X, B(X))$-valued random variables and $(Y_n)_{n \geq 1}$ be a sequence of $(Y, B(Y))$-valued random variables. Assuming there exists a certain random variable $X$ such that $X_n \to X$ $\mathcal{G}$-stably, the following statements hold.

(A) Let $X = Y$. If $d(X_n, Y_n) \to 0$ in probability, $Y_n \to X$ $\mathcal{G}$-stably.

(B) If $Y_n \to Y$ in probability and $Y$ is $\mathcal{G}$-measurable, $(X_n, Y_n) \to (X, Y)$ $\mathcal{G}$-stably.

(C) If $g : X \to Y$ is $(B(X), B(Y))$-measurable and continuous $P^X$-a.s., $g(X_n) \to g(X)$ $\mathcal{G}$-stably.

Remark 2.4. Note that (B) is the generalization of the classical Slutsky’s lemma to stable convergence. To make the assertion meaningful, we need to take a large sub $\sigma$-field $\mathcal{G}$, but if we take it too large, the $\mathcal{G}$-stable convergence of $X_n$ may not hold.

Lemma 2.5 ([10, p. 109]). Let $(X_n)_{n \geq 1}$ be a martingale difference sequence with respect to a filtration $\mathcal{F} = (\mathcal{F}_m)_{m=1}^\infty$ and define $\mathcal{F}_\infty := \sigma(\bigcup_{m=1}^\infty \mathcal{F}_m)$. For a sequence of positive real number $(a_m)_{m \geq 1}$ with $a_m \to \infty$, we assume the following two conditions:

(i) $a_m^{-2} \sum_{n=1}^m \mathbb{E}[|X_n^2|\mathcal{F}_{n-1}] \to \eta^2$ in probability for some random variable $\eta \geq 0$.

(ii) $a_m^{-2} \sum_{n=1}^m \mathbb{E}[X_n^2I\{|X_n| \geq ca_m\}\mathcal{F}_{n-1}] \to 0$ in probability for all $\epsilon > 0$.

Then, the following holds: $a_m^{-1} \sum_{n=1}^m X_n \to \eta N \mathcal{F}_\infty$-stably where $N \sim N(0,1)$ is independent of $\mathcal{F}_\infty$.

Corollary 2.5.1. In the setting of Lemma 2.5, if $X_n$ is a bounded random variable for all $n \in \mathbb{N}$, (i) is sufficient for the assertion to hold.

Proof. It suffices to show that (ii) in Lemma 2.5 is satisfied automatically. By the assumption, there exists a constant value $C$, such that $|X_n| \leq C$. Conversely, $a_m \to \infty$ implies that there exists a integer $N_\epsilon$ for all $\epsilon > 0$, such that $m \geq N_\epsilon \Rightarrow a_m > C/\epsilon$. Note that $m > N_\epsilon \Rightarrow |X_n| < C < a_m \epsilon$. Then, for all $m > N_\epsilon$, $\sum_{n=1}^m \mathbb{E}[X_n^2I\{|X_n| \geq \epsilon a_m\}\mathcal{F}_{n-1}] = \sum_{n=1}^{N_\epsilon} \mathbb{E}[X_n^2I\{|X_n| \geq \epsilon a_m\}\mathcal{F}_{n-1}] \leq N_\epsilon C^2 < +\infty$, which implies $a_m^{-2} \sum_{n=1}^m \mathbb{E}[X_n^2I\{|X_n| \geq \epsilon a_m\}\mathcal{F}_{n-1}] \to 0$ (a.s.), especially in probability. Therefore, (ii) holds. $\square$

3 Main result
From now on, we shall always assume $0 < \alpha < 1$ and $\theta > -\alpha$.

3.1 Fisher Information
We define Fisher Information of Sibuya distribution, denoted by $I(\alpha)$, and expressed as

$$I(\alpha) := -\sum_{j=1}^{\infty} p_\alpha(j) \cdot \partial_\alpha^2 \log p_\alpha(j), \quad p_\alpha(j) = \frac{\alpha \prod_{i=1}^{j-1}(i-\alpha)}{j!}.$$  \hspace{1cm} (3.1)

Proposition 3.1. $I(\alpha)$ defined by (3.1) is continuous on $(0, 1)$ with the following expressions:

$$I(\alpha) \overset{(A)}{=} \frac{1}{\alpha^2} + \sum_{j=1}^{\infty} p_\alpha(j) \sum_{i=1}^{j-1} \frac{1}{(i-\alpha)^2} \overset{(B)}{=} \frac{1}{\alpha^2} + \sum_{j=1}^{\infty} \frac{p_\alpha(j)}{\alpha(j-\alpha)} > 0.$$

Sketch of proof. Use Fubini-Tonelli’s theorem and equation $\sum_{j=i+1}^{\infty} p_\alpha(j) = p_\alpha(i)(i-\alpha)/\alpha$. See the Supplementary Material for details. $\square$
Both (A) and (B) appear in the proof of our main result. In contrast, the computation of $I(\alpha)$ is required for the confidence interval proposed by Corollary 3.9.1. In this case, formula (B) is better in terms of numerical errors, considering $p_\alpha(j) = O(j^{-\alpha-1})$ implies $\sum_{j=\alpha}^{\infty} p_\alpha(j) \sum_{i=1}^{j-1} (i - \alpha)^{-2} = O(n^{-\alpha})$ and $\sum_{j=\alpha}^{\infty} p_\alpha(j) (\alpha(j - \alpha))^{-1} = O(n^{-\alpha-1})$. We plot the graph of $I(\alpha)$ in Figure 3 using formula (B) with $j$ truncated at $10^5$. It may be possible to express $I(\alpha)$ without infinite series by utilizing special functions, which is one of our future research topics.

Towards the analysis of Fisher information of Ewens–Pitman partition below and the asymptotics of the MLE for $\theta$ in Section 3.3, we define the function $f_\alpha : (1, \infty) \to \mathbb{R}$ for each $\alpha \in (0, 1)$ by

$$f_\alpha : z \mapsto \psi(1 + z) - \alpha \psi(1 + \alpha z), \quad (3.2)$$

where $\psi(x) = \Gamma'(x)/\Gamma(x)$ is the digamma function.

**Lemma 3.2.** For each $\alpha \in (0, 1)$, the map $f_\alpha : (1, \infty) \to \mathbb{R}$ defined by (3.2) is bijective with $f_\alpha'(z) > 0$ and $f_\alpha''(z) < 0$ for all $z \in (-1, \infty)$.  

**Proof.** See the Supplementary Material. □

We define the logarithm of the likelihood given by (1.1), denoted by $l_n(\alpha, \theta)$ and expressed as

$$l_n(\alpha, \theta) := \frac{K_n}{\alpha} - \frac{n-1}{\alpha} \log(\theta + i\alpha) - \sum_{i=1}^{n-1} \log(\theta + i) + \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \log(i - \alpha). \quad (3.3)$$

Furthermore, we define $I^{(n)}_{\alpha \alpha}$, $I^{(n)}_{\alpha \theta}$, and $I^{(n)}_{\theta \theta}$ by

$$I^{(n)}_{\alpha \alpha} := \mathbb{E}[(\partial_\alpha l_n(\alpha, \theta))^2], \quad I^{(n)}_{\alpha \theta} := \mathbb{E}[\partial_\alpha l_n(\alpha, \theta) \cdot \partial_\theta l_n(\alpha, \theta)], \quad I^{(n)}_{\theta \theta} := \mathbb{E}[(\partial_\theta l_n(\alpha, \theta))^2]. \quad (3.4)$$

Note that they can be interpreted as Fisher information about $(\alpha, \theta)$ that is obtained by the partition of $n$ balls under Ewens–Pitman partition.

**Proposition 3.3.** For $(\alpha, \theta)$ satisfying $0 < \alpha < 1, \theta > -\alpha$, the leading terms of (3.4) are given by

$$I^{(n)}_{\alpha \alpha} \sim n^\alpha \mathbb{E}[M_{\alpha \theta}] I(\alpha), \quad I^{(n)}_{\alpha \theta} \sim (n^\alpha \log n), \quad I^{(n)}_{\theta \theta} \sim \alpha^{-2} f_\alpha'(\theta/\alpha) < +\infty$$

where $I(\alpha)$ is defined by (3.1), $f_\alpha'$ is the derivative of $f_\alpha$ defined by (3.2), and $M_{\alpha \theta} \sim \text{GMtL}(\alpha, \theta)$.  

**Proof.** See the Supplementary Material. [18] has already given these orders without derivation. □
3.2 Maximum Likelihood Estimator for $\alpha$ when $\theta$ is known

**Definition 3.1** (MLE for $\alpha$ with $\theta$ known). Suppose $0 < \alpha < 1$ and $\theta > -\alpha$. We define $\hat{\alpha}_{n, \theta}$ by

$$\hat{\alpha}_{n, \theta} := \arg\max_{x \in (-\theta, 0, 1)} l_n(\alpha = x, \theta),$$

where $l_n(\alpha, \theta)$ is the log-likelihood expressed by (3.3).

Before we prove the consistency and asymptotic mixed normality of $\hat{\alpha}_{n, \theta}$, we argue its uniqueness.

We define the random function $\hat{\Psi}_{n, \theta}$ on $(-\theta \lor 0, 1)$ by

$$\forall x \in (-\theta \lor 0, 1), \quad \hat{\Psi}_{n, \theta}(x) := \frac{\partial_x l_n(x, \theta)}{K_n} = \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i^2}{\theta + ix} - \frac{n}{K_n} \sum_{j=1}^{n} \frac{1}{j - x}. \tag{3.5}$$

Suppose $n \geq 2$. Then, $\hat{\Psi}_{n, \theta}(x)$ is strictly decreasing on $(-\theta \lor 0, 1)$ considering it holds that

$$\forall x \in (-\theta \lor 0, 1), \quad \hat{\Psi}_{n, \theta}'(x) = -\frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i^2}{(\theta + ix)^2} - \frac{n}{K_n} \sum_{j=1}^{n} \frac{1}{(i - x)^2} < 0, \tag{3.6}$$

with probability 1 (if $1 < K_n$ the first term in (3.6) is strictly negative; else, $S_{n,j} = n \geq 2$ implies the negativeness of the second term). Therefore, $\hat{\alpha}_{n, \theta}$ exists and equals the unique solution of $\hat{\Psi}_{n, \theta}(x) = 0$ if and only if $\lim_{x \to (-\theta \lor 0)} \hat{\Psi}_{n, \theta}(x) > 0 > \lim_{x \to -1} \hat{\Psi}_{n, \theta}(x)$. The necessary and sufficient condition for that is given by [1, Lemma 5.1]

$$1 < K_n < n \text{ and } \theta < \Theta_n := \frac{K_n(K_n - 1)}{\sum_{j=2}^{\infty} S_{n,j} \sum_{i=1}^{j-1} i^{-1}}. \tag{3.7}$$

See the Supplementary Material for the derivation of (3.7). Note that (1.1) and Stirling’s formula imply

$$\Pr(K_n = n) = \prod_{i=1}^{n-1} \left(\frac{\theta + i\alpha}{\theta + i}\right)^n < \begin{cases} \left(\frac{\theta + \alpha}{\theta + 1}\right)^n, & \theta \geq 0 \\ \alpha^n, & \alpha < \theta < 0, \end{cases}$$

$$\Pr(K_n = 1) = \prod_{i=1}^{n-1} \left(\frac{i - \alpha}{i + \theta}\right) = \frac{\Gamma(1 + \theta)\Gamma(n - \alpha)}{\Gamma(n + \theta)\Gamma(1 - \alpha)} \sim \frac{\Gamma(1 + \theta)}{\Gamma(1 - \alpha)} n^{-(\theta + \alpha)},$$

so, $\Pr(\{1 < K_n < n\}) = \Pr(K_n = 1) + \Pr(K_n = n) = O(n^{-(\theta + \alpha)}) = o(1)$ by $\theta + \alpha > 0$. Conversely, Lemma 2.1 and Corollary 3.6.1 applied with $x = 0$ yield

$$\Theta_n = \frac{n^\alpha}{\sum_{j=2}^{\infty} S_{n,j}/K_n \sum_{i=1}^{j-1} i^{-1}} \rightarrow \frac{M_{\alpha \theta}}{2 \sum_{j=2}^{\infty} p_{\alpha}(j) \sum_{i=1}^{j-1} i^{-1}} \lessgtr +\infty \text{ in probability},$$

and hence $\Pr(\theta \geq \Theta_n) \rightarrow 0$. For these reasons, $\hat{\Psi}_{n, \theta}(x)$ is a strictly decreasing function on $(-\theta \lor 0, 1)$ and $\hat{\alpha}_{n, \theta}$ in Definition 3.1 is the unique root of $\hat{\Psi}_{n, \theta}$ with high probability.

Towards the proof of consistency, we define the deterministic function $\Psi(\cdot; \alpha) : (0, 1) \rightarrow \mathbb{R}$ with parameter $\alpha \in (0, 1)$ by

$$\forall x \in (0, 1), \quad \Psi(x) = \Psi(x; \alpha) := \frac{1}{x} - \sum_{j=2}^{\infty} p_{\alpha}(j) \sum_{i=1}^{j-1} \frac{1}{i - x}. \tag{3.8}$$

**Lemma 3.4.** For the function $\Psi$ defined by (3.8), the following assertions hold.
(A) \( \Psi \) is of class \( C^1 \) on \((0,1)\).

(B) \( \Psi(x) = -x^{-2} - \sum_{j=2}^{\infty} p_n(j) \sum_{i=1}^{j-1} (i-x)^{-2} < 0 \) and hence \( \Psi'(x = \alpha) = -I(\alpha) \) where \( I(\alpha) \) is Fisher information of Sibuya distribution defined by (3.1).

(C) \( \Psi(x = \alpha) = 0 \).

Sketch of proof. (A) and (B) can be shown by elementary calculation. (C) follows from the fact \( \partial_\alpha \sum_{j=1}^{\infty} p_n(j) = \partial_\alpha 1 = 0 \) and interchange of the differential and summation. See the Supplementary Material for details.

To show a suitable convergence of \( \hat{\Psi}_{n,\theta} \) to \( \Psi \), we provide the following Lemma.

**Lemma 3.5.** \( \sum_{j=1}^{\infty} |S_{n,j}/K_n - p_\alpha(j)| \to 0 \) (a.s.).

**Sketch of proof.** We use (B) of Lemma 2.1 and the logic of the dominated convergence theorem. See the Supplementary Material for details.

**Corollary 3.5.1.** For any bounded function \( g : \mathbb{N} \to \mathbb{R} \), \( \sum_{j=1}^{\infty} (S_{n,j}/K_n - p_\alpha(j)) g(j) \to 0 \) (a.s.).

**Proof.** Let us take a positive constant \( C \) s.t. \( |g(j)| \leq C \) for all \( j \in \mathbb{N} \). Then, Lemma 3.5 implies \( |\sum_{j=1}^{\infty} (S_{n,j}/K_n - p_\alpha(j)) g(j)| \leq \sum_{j=1}^{\infty} |S_{n,j}/K_n - p_\alpha(j)||g(j)| \leq C \sum_{j=1}^{\infty} |S_{n,j}/K_n - p_\alpha(j)| \to 0 \) (a.s.).

**Lemma 3.6.** For all \( x \in (-\theta \cup 0, 1) \), \( \hat{\Psi}_{n,\theta}(x) \to \Psi(x) \) in probability.

**Proof.** For all \( \epsilon > 0 \), note \( \Pr(\|n^{-\alpha} \cdot \partial_\alpha l_n(\alpha, \theta)\| > \epsilon) \leq n^{-2\alpha} \epsilon^{-2} I_\alpha^{(n)} = O(n^{-\alpha}) \) by Chebyshev’s inequality and \( I_\alpha^{(n)} = O(n^\alpha) \) (Proposition 3.3) and hence \( n^{-\alpha} \partial_\alpha l_n(\alpha, \theta) = o_p(1) \). Then, \( K_n/n^\alpha \to M_{\alpha,\theta} > 0 \) (a.s.) by (B) of Lemma 2.1 (hence \( n^\alpha/K_n = O_p(1) \)) and \( \Psi(\alpha) = 0 \) by (C) of Lemma 3.4 yield \( \hat{\Psi}_{n,\theta}(\alpha) - \Psi(\alpha) = n^\alpha/K_n \cdot n^{-\alpha} \partial_\alpha l_n(\alpha, \theta) - 0 = O_p(1) o_p(1) = o_p(1) \). Here we fix \( x \in (-\theta \cup 0, 1) \). Then, triangle inequality results in \( |\hat{\Psi}_{n,\theta}(x) - \Psi(x)| \leq |\hat{\Psi}_{n,\theta}(x) - \Psi(x) - (\hat{\Psi}_{n,\theta}(\alpha) - \Psi(\alpha))| + o_p(1) \). From (3.5), (3.8), for all \( \hat{x} \in (-\theta \cup 0, 1) \), it holds that

\[
\hat{\Psi}_{n,\theta}(\hat{x}) - \Psi(\hat{x}) = \frac{1}{x K_n} \sum_{i=1}^{K_n-1} \left( \frac{1}{x} + \frac{\theta + i \hat{x}}{\frac{\theta}{x} + i \hat{x}} \right) - \frac{1}{x K_n} \sum_{i=1}^{K_n-1} \frac{1}{x + i \hat{x}} - \frac{1}{x K_n} \sum_{i=1}^{K_n-1} \frac{1}{x + i \hat{x}}
\]

Therefore, \( |\hat{\Psi}_{n,\theta}(x) - \Psi(x) - (\hat{\Psi}_{n,\theta}(\alpha) - \Psi(\alpha))| \) is bounded above by

\[
\left| \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \frac{1}{x K_n} \left( \frac{1}{i - x} - \frac{1}{i - \alpha} \right) \right| + \frac{|\theta|}{x K_n} \sum_{i=1}^{K_n-1} \frac{1}{\theta + i \alpha} + \frac{1}{\theta + i \alpha} + \frac{|\theta|}{\alpha K_n} \sum_{i=1}^{K_n-1} \frac{1}{\theta + i \alpha},
\]

where the first term is \( o_p(1) \) by Corollary 3.5.1 applied with \( g(j) = \sum_{i=1}^{j-1} ((i-x)^{-1} - (i-\alpha)^{-1}) \).

The remaining terms are clearly \( o_p(1) \) from \( K_n \to \infty \) and \( K_n^{-1} \log K_n \to 0 \) (a.s.). This concludes the proof.

**Corollary 3.6.1.** For all \( x \in [0, 1] \), \( \sum_{j=2}^{n} (S_{n,j}/K_n) \sum_{i=1}^{j-1} (i-x)^{-1} \to \sum_{j=2}^{\infty} p_\alpha(j) \sum_{i=1}^{j-1} (i-x)^{-1} < +\infty \) in probability.

**Proof.** The convergence of the limit follows by the same argument for the convergence of \( \Psi(x) \) in Lemma 3.4. Note that (3.9) with \( \hat{x} = \alpha \) and Lemma 3.6 lead to the assertion when \( x = \alpha \). For \( x \neq \alpha \), apply Corollary 3.5.1 again with \( g(j) = \sum_{i=1}^{j-1} ((i-x)^{-1} - (i-\alpha)^{-1}) \).
Lemma 3.7 (Consistency). For $\hat{\alpha}_{n,\theta}$ in Definition 3.1, $\hat{\alpha}_{n,\theta} \to \alpha$ in probability.

Proof. Recall that $\hat{\Psi}'_{n,\theta}(x) < 0$ for all $x \in (-\theta \vee 0, 1)$, and with high probability, its root uniquely exists and equals $\hat{\alpha}_{n,\theta}$. Then, for all $\epsilon > 0$ satisfying $\epsilon < (\alpha - (-\theta \vee 0)) \wedge (1 - \alpha)$, we have $\Pr (|\hat{\alpha}_{n,\theta} - \alpha| > \epsilon) \leq \Pr (\hat{\alpha}_{n,\theta} < \alpha - \epsilon) + \Pr (\hat{\alpha}_{n,\theta} > \alpha + \epsilon) \leq \Pr (0 > \hat{\Psi}_{n,\theta}(\alpha - \epsilon)) + \Pr (0 < \hat{\Psi}_{n,\theta}(\alpha + \epsilon))$. Conversely, (B) and (C) of Lemma 3.4 imply $\hat{\Psi}(\alpha - \epsilon) > \hat{\Psi}(\alpha) = 0 > \hat{\Psi}(\alpha + \epsilon)$. Then Lemma 3.6 implies $\Pr (0 > \hat{\Psi}_{n,\theta}(\alpha - \epsilon)) = \Pr (\hat{\Psi}(\alpha - \epsilon) - \hat{\Psi}_{n,\theta}(\alpha - \epsilon) > \hat{\Psi}(\alpha - \epsilon) > 0) = o(1)$ and $\Pr (0 < \hat{\Psi}_{n,\theta}(\alpha + \epsilon)) = \Pr (\hat{\Psi}(\alpha + \epsilon) - \hat{\Psi}_{n,\theta}(\alpha + \epsilon) > -\hat{\Psi}(\alpha + \epsilon) > 0) = o(1)$. Therefore, we have $\Pr (|\hat{\alpha}_{n,\theta} - \alpha| > \epsilon) \to 0$, completing the proof. \hfill \Box

Now we define $F_n$ as the $\sigma$-filed generated by the partitions of $n$ balls under Ewens–Pitman partition, and denote the $\sigma$-filed $\sigma(\cup_{n=1}^{\infty}F_n)$ by $F_{\infty}$.

Lemma 3.8. For $I(\alpha)$ and $l_n(\alpha, \theta)$ defined by (3.1) and (3.3), it holds that

$$n^{-\alpha/2} \cdot \partial_{\alpha} l_n(\alpha, \theta) \to \sqrt{M_{\alpha \theta}} I(\alpha) \cdot N \text{ } F_{\infty} \text{-stably as } n \to \infty,$$

where $M_{\alpha \theta} = \lim_{n \to \infty} n^{-\alpha}K_n \sim \text{GMMgf}(\alpha, \theta)$ and $N \sim \mathcal{N}(0, 1)$ is independent of $F_{\infty}$.

Proof. We will apply Corollary 2.5.1 with $X_n$ regarded as the increment of the score function $\partial_{\alpha} l_n(\alpha, \theta) = \sum_{i=1}^{K_n-1} i/(\theta + i) - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} (i - \alpha)^{-1}$ and $a_m = \alpha^{m/2}$. Note that score function is $\mathcal{F}_n$-martingale in general, and hence $(X_n)_{n=1}^{\infty}$ is a $\mathcal{F}_n$-martingale difference sequence (or we can check it directly by the argument in Step 1 below).

Step 1. $\exists C > 0$ s.t. $|X_n| \leq C$ for all $n \in \mathbb{N}$: By the sequential definition of Ewens–Pitman partition in Section 2.3, we get:

- With probability $(\theta + K_n\alpha)/(\theta + n)$,
  $$K_{n+1} = K_n + 1, S_{n+1,1} = S_{n,1} + 1, S_{n+1,j} = S_{n,j} (j \geq 2),$$
  and hence $X_n = K_n/(\theta + \alpha K_n)$, which is positive and bounded above by $(\theta + \alpha)^{-1} \vee \alpha^{-1}$.

- With probability $S_{n,j}(l - \alpha)/(\theta + n)$ ($l = 1, 2, \ldots, n$),
  $$K_{n+1} = K_n, S_{n+1,l} = S_{n,l} - 1, S_{n+1,l+1} = S_{n,l+1} + 1,$$
  and $S_{n+1,j} = S_{n,j} (j \notin \{l, l+1\})$. Then $X_n = \sum_{i=1}^{l-1} (i - \alpha)^{-1} - \sum_{i=1}^{l} (i - \alpha)^{-1} = -(l - \alpha)^{-1}$, which is negative and lower bounded by $- (1 - \alpha)^{-1}$.

Therefore, $|X_n| \leq (\theta + \alpha)^{-1} \vee \alpha^{-1} \vee (1 - \alpha)^{-1} = C$.

Step 2. $\alpha^{-m} \sigma_m^2 \to I(\alpha) M_{\alpha \theta}$ (a.s.): Note that $\sigma_m^2 = \sum_{n=1}^{m} \mathbb{E} [X_n^2 | F_n]$ is calculated as

$$\sigma_m^2 = \sum_{n=1}^{m} \left\{ \frac{\theta + n K_n}{\theta + n} \left( \frac{K_n}{\theta + n K_n} \right)^2 + \sum_{j=1}^{n} \frac{j - \alpha}{\theta + n} S_{n,j} \left( \frac{1}{j - \alpha} \right)^2 \right\}$$

$$= \sum_{n=1}^{m} \frac{\theta^{\alpha-1}}{n + \theta} \frac{n}{n + \theta} \frac{K_n}{\alpha^2 (\theta + K_n)} + \sum_{j=1}^{n} \frac{S_{n,j}}{K_n} \frac{1}{\alpha (j - \alpha)} = \sum_{n=1}^{m} \hat{c}_n X_n. \quad (3.10)$$

Note that $n^{-\alpha} K_n \to M_{\alpha \theta}$ (a.s.) by Lemma 2.1, (B) of Proposition 3.1, and Corollary 3.5.1 applied with $g(j) = (j - \alpha)^{-1}$ yield

$$X_n \to 1 \cdot M_{\alpha \theta} \cdot \left( \frac{1}{\alpha^2} + \sum_{j=1}^{\infty} \frac{p_{\alpha}(j)}{\alpha (j - \alpha)} \right) = M_{\alpha \theta} I(\alpha) \text{ (a.s.).} \quad (3.11)$$
Now we rewrite (3.10) as follows;

\[ m^{-\alpha} \sigma_m^2 = M_{\alpha \theta} I(\alpha) \cdot m^{-\alpha} \sum_{n=1}^{m} c_n + m^{-\alpha} \sum_{n=1}^{m} c_n (X_n - M_{\alpha \theta} I(\alpha)). \] (3.12)

Note \( m^\alpha = \int_{0}^{m} \alpha x^{\alpha-1} dx < \sum_{n=1}^{m} c_n = \sum_{n=1}^{m} \alpha n^{\alpha-1} < \int_{1}^{m+1} \alpha x^{\alpha-1} dx = (m + 1)^\alpha - 1 \) for all \( m \in \mathbb{N} \), which implies that \( m^{-\alpha} \sum_{n=1}^{m} c_n \to 1 \) as \( m \to \infty \). Then, the first term in (3.12) converges to \( M_{\alpha \theta} I(\alpha) \) (a.s.). Then, we fix \( \epsilon > 0 \). (3.11) implies that \( \exists N_\epsilon \in \mathbb{N} \), such that \( \forall n > N_\epsilon, |X_n - M_{\alpha \theta} I(\alpha)| < \epsilon \). Then, the absolute value of the second term in (3.12) is bounded above by

\[ m^{-\alpha} \sum_{n=1}^{m} c_n |X_n - M_{\alpha \theta} I(\alpha)| \leq m^{-\alpha} \sum_{n=1}^{N_\epsilon} c_n |X_n - M_{\alpha \theta} I(\alpha)| + \epsilon \cdot m^{-\alpha} \sum_{n=N_\epsilon+1}^{m} c_n \to \epsilon \text{ (a.s.),} \]

and hence, \( 0 \leq \limsup_{m \to \infty} m^{-\alpha} \sum_{n=1}^{m} c_n (X_n - M_{\alpha \theta} I(\alpha)) < \epsilon \). Considering we took \( \epsilon > 0 \) arbitrarily, we have \( m^{-\alpha} \sum_{n=1}^{m} n^{\alpha-1} (X_n - M_{\alpha \theta} I(\alpha)) \to 0 \) (a.s.). Therefore, \( m^{-\alpha} \sigma_m^2 \to M_{\alpha \theta} I(\alpha) \) (a.s.).

**Theorem 3.9.** For \( \hat{\alpha}_{n,\theta} \) in Definition 3.1 the following holds:

\[ \sqrt{n^\alpha I(\alpha)} \cdot (\hat{\alpha}_{n,\theta} - \alpha) \to N/\sqrt{M_{\alpha \theta}} \quad \text{F}_\infty \text{-stably as } n \to \infty, \] (3.13)

where \( M_{\alpha \theta} = \lim_{n \to \infty} n^{-\alpha} K_n \sim \text{GMtLf}(\alpha, \theta) \), \( N \sim N(0,1) \) is independent of \( \mathcal{F}_\infty \), and \( I(\alpha) \) is Fisher information of the Sibuya distribution defined by (3.1).

**Proof.** Recall \( \Psi'_{n,\theta}(\hat{\alpha}_{n,\theta}) < 0 \) and \( \Psi_{n,\theta}(\hat{\alpha}_{n,\theta}) = 0 \) with high probability. We apply Taylor’s theorem on the left side so that there exists \( \hat{\alpha} \) that satisfies \( |\hat{\alpha} - \alpha| \sqrt{|\hat{\alpha} - \alpha|} \leq |\hat{\alpha} - \alpha| \leq |\hat{\alpha} - \alpha| \) (hence \( \hat{\alpha} = \alpha \)) by Lemma 3.7 and \( 0 = \Psi_{n,\theta}(\hat{\alpha}) + \Psi'_{n,\theta}(\hat{\alpha})(\hat{\alpha} - \alpha) \). Therefore, we get

\[ \sqrt{I(\alpha)n^\alpha} \cdot (\hat{\alpha}_{n,\theta} - \alpha) = \sqrt{I(\alpha)n^\alpha} \cdot \frac{\Psi_{n,\theta}(\hat{\alpha})}{\Psi'_{n,\theta}(\hat{\alpha})} = \frac{\partial_n I_n(\alpha, \theta)}{\sqrt{n^\alpha I(\alpha)}} - \frac{I(\alpha)}{\Psi'_{n,\theta}(\hat{\alpha})} \frac{n^\alpha}{N_n}. \]

Note that Corollary 3.17.1 applied with \( \theta' = \theta \) and \( K_n/n^\alpha \to M_{\alpha \theta} \) (a.s.) implies \( Y_n \to 1/M_{\alpha \theta} \) in probability. Since \( M_{\alpha \theta} \) is \( \mathcal{F}_\infty \)-measurable, Lemma 3.8 and (B) of Lemma 2.3 imply \( (X_n, Y_n) \to (\sqrt{M_{\alpha \theta} N, M_{\alpha \theta}^{-1}}) \) \( \mathcal{F}_\infty \)-stably, where \( N \sim N(0,1) \) is independent of \( \mathcal{F}_\infty \). Then, (C) of Lemma 2.3 applied with \( g(x, y) = xy \) results in

\[ \sqrt{I(\alpha)n^\alpha} \cdot (\hat{\alpha}_{n,\theta} - \alpha) = g(X_n, Y_n) \to g(\sqrt{M_{\alpha \theta} N, M_{\alpha \theta}^{-1}}) = N/\sqrt{M_{\alpha \theta}} \quad \text{F}_\infty \text{-stably,} \]

completing the proof.

**Corollary 3.9.1 (Confidence Interval).** In the same setting as Theorem 3.9, it holds that

\[ \sqrt{I(\alpha)K_n} \cdot (\hat{\alpha}_{n,\theta} - \alpha) \to N \text{ F}_\infty \text{-mixing,} \] (3.14)

and hence, \( \hat{\alpha}_{n,\theta} \pm 1.96/\sqrt{I(\hat{\alpha}_{n,\theta})K_n} \) is a 95% confidence interval for \( \alpha \).

**Proof.** By applying Lemma 2.3 again, we have \( \sqrt{I(\alpha)K_n} \cdot (\hat{\alpha}_{n,\theta} - \alpha) = \sqrt{K_n/n^\alpha} \cdot \sqrt{n^\alpha I(\alpha)}(\hat{\alpha}_{n,\theta} - \alpha) \to \sqrt{M_{\alpha \theta} \cdot N/\sqrt{M_{\alpha \theta}}} = N \quad \text{F}_\infty \text{-mixing.} \) In contrast, the consistency of \( \hat{\alpha}_{n,\theta} \) (Lemma 3.7) and continuity of \( I(\alpha) \) on \( (0,1) \) (Proposition 3.1) imply \( I(\hat{\alpha}_{n,\theta}) \to I(\alpha) \) in probability. Therefore, \( \sqrt{I(\hat{\alpha}_{n,\theta})K_n} \cdot (\hat{\alpha}_{n,\theta} - \alpha) = \sqrt{I(\hat{\alpha}_{n,\theta})I(\alpha)I(\alpha)K_n} \cdot (\hat{\alpha}_{n,\theta} - \alpha) \to N \quad \text{F}_\infty \text{-mixing,} \) which yields the confidence interval.
Figure 4: Errors of empirical CDFs of $\sqrt{I_{\alpha}^{(n)}}(\hat{\alpha}_{n,\theta} - \alpha)$ (left) and $\sqrt{K_{n}(\alpha)}(\hat{\alpha}_{n,\theta} - \alpha)$ (right) to the CDF of $N(0,1)$ with $(\alpha,\theta)$ fixed to $(0.8,0)$.

Note that Theorem 3.9 and Proposition 3.3 imply

$$\sqrt{I_{\alpha}^{(n)}}(\hat{\alpha}_{n,\theta} - \alpha) \rightarrow \sqrt{E[M_{\alpha \theta}]/M_{\alpha \theta}} \cdot N_{\mathcal{F}_\infty},$$

where $M_{\alpha \theta} \sim \text{GMtL}(\alpha,\theta)$ is $\mathcal{F}_\infty$ measurable and $N \sim N(0,1)$ is independent of $\mathcal{F}_\infty$. Note that the limit law is mixed normal owing to the randomness of $M_{\alpha \theta}$. In particular, Jensen’s inequality implies that its $p$-th moment is larger than that of $N(0,1)$ for all $p > 0$. Conversely, the deviation of the limit law to $N(0,1)$ is small when $\theta$ is large or $\alpha$ is small as follows.

**Proposition 3.10.** As $\theta \rightarrow \infty$ with $0 < \alpha < 1$ fixed or $\alpha \rightarrow 0$ with $\theta > 0$ fixed, the limit law in (3.15) converges to $N(0,1)$ in $p$-th moment for all $p > 0$ and hence weakly.

**Proof.** Note that the weak convergence directly follows from the moment convergence by the method of moment. Considering the independence of $M_{\alpha \theta}$ and $N$, it suffices to show $E[(M_{\alpha \theta})^p] E[M_{\alpha \theta}^{-p}] \rightarrow 1$ for all $p > 0$. Note that (2.3) and Stirling’s formula imply

$$E[(M_{\alpha \theta})^q] = \frac{\Gamma(\theta + 1)}{\Gamma(\theta + 1 + q\alpha)} \frac{\Gamma(\theta/\alpha + 1 + q)}{\Gamma(\theta/\alpha + 1)} \sim \left\{ \begin{array}{ll} (\theta^{1-\alpha}/\alpha)^q & \text{as } \theta \rightarrow \infty \text{ with } \alpha \text{ fixed s.t. } 0 < \alpha < 1 \\ (\theta/\alpha)^q & \text{as } \alpha \rightarrow 0 \text{ with } \theta \text{ fixed s.t. } \theta > 0 \end{array} \right.$$ for all $q \in \mathbb{R}$. Therefore, for all $p > 0$ it holds that

$$E[M_{\alpha \theta}]^p E[M_{\alpha \theta}^{-p}] \sim \left\{ \begin{array}{ll} (\theta^{1-\alpha}/\alpha)^p \cdot (\theta^{1-\alpha}/\alpha)^{-p} & \text{as } \theta \rightarrow \infty \text{ with } \alpha \text{ fixed s.t. } 0 < \alpha < 1 \\ (\theta/\alpha)^p \cdot (\theta/\alpha)^{-p} & \text{as } \alpha \rightarrow 0 \text{ with } \theta \text{ fixed s.t. } \theta > 0 \end{array} \right.$$ and hence $E[M_{\alpha \theta}]^p E[M_{\alpha \theta}^{-p}] \rightarrow 1$, which completes the proof.

Finally, we visualize the difference of (3.14) and (3.15). For $(\alpha, \theta) = (0.8,0)$, we calculate the empirical CDFs of the left hand sides in (3.14) and (3.15) with sample size $10^3$ and plot their error to the CDF of $N(0,1)$ in Figure 4. We see that the error of the empirical CDF of $\sqrt{K_{n}(\alpha)}(\hat{\alpha}_{n,\theta} - \alpha)$ uniformly converges to 0 while the tail of $\sqrt{I_{\alpha}^{(n)}}(\hat{\alpha}_{n,\theta} - \alpha)$ does not converge to 0.

### 3.3 Maximum Likelihood Estimator for $\theta$ when $\alpha$ is known

**Definition 3.2 (MLE for $\theta$ with $\alpha$ known).** Suppose $0 < \alpha < 1$, $\theta > -\alpha$. We define $\hat{\theta}_{n,\alpha}$ by

$$\hat{\theta}_{n,\alpha} := \arg \max_{y > -\alpha} l_n(\alpha, \theta = y),$$

where $l_n(\alpha, \theta)$ is the log-likelihood expressed by (3.3).
We define the random function $\Phi_{n,\alpha}(y)$ on $(-\alpha, \infty)$ by
\[
\Phi_{n,\alpha}(y) := \partial_y l_n(\alpha, y) = \frac{K_n-1}{y + \alpha} - \sum_{i=1}^{n-1} \frac{1}{y + i}.
\]

**Lemma 3.11** ([1, Lemma 5.3]). If $1 < K_n < n$, $\Phi_{n,\alpha}$ has $\hat{\theta}_{n,\alpha}$ as the unique root.

**Proof.** See [1, Lemma 5.3], or the Supplementary Material, where we show the assertion in a more general setting with $\alpha$ replaced by $x$ for any $x \in (0,1)$.

**Lemma 3.12.** For the digamma function $\psi$, $\psi(n + \delta_n) - \log n = o(1)$ for all $\delta_n = o(n)$.

**Proof.** Use $\psi(n) - \log n = o(1)$ (see, for example, [20, Section 6]) and $\log(n + \delta_n) - \log n = \log(1 + \delta_n/n) = o(1)$.

**Proposition 3.13** ([1, Lemma 5.7]). For $\hat{\theta}_{n,\alpha}$ in Definition 3.2, it holds that
\[
\psi(1 + \hat{\theta}_{n,\alpha}/\alpha) - \alpha \psi(1 + \hat{\theta}_{n,\alpha}) \to \log M_{\alpha \theta} \ (a.s.),
\]
where $M_{\alpha \theta} \sim \text{GMedL}(\alpha, \theta)$ and $\psi$ is the digamma function.

**Sketch of proof.** We show the sketch of the original proof given by [1, p. 85]. Suppose $\hat{\theta}_{n,\alpha}/K_n \to 0$ (a.s.) holds. (This can be easily shown). Then, $\sum_{i=1}^{m-1} (i + \delta)^{-1} = \psi(m + \delta) - \psi(1 + \delta)$ for all $m \leq 1$ and $\delta > -1$ with Lemma 3.12 applied with the assumption $\hat{\theta}_{n,\alpha}/K_n \to 0$ (a.s.) (and hence $\hat{\theta}_{n,\alpha}/n \to 0$ (a.s.)) results in
\[
0 = \alpha \cdot \Phi_{n,\alpha}(\hat{\theta}_{n,\alpha}) = \psi(K_n + \hat{\theta}_{n,\alpha}/\alpha) - \psi(1 + \hat{\theta}_{n,\alpha}/\alpha) - \alpha \psi(n + \hat{\theta}_{n,\alpha}) + \alpha \psi(1 + \hat{\theta}_{n,\alpha})
\Rightarrow \psi(1 + \hat{\theta}_{n,\alpha}/\alpha) - \alpha \psi(1 + \hat{\theta}_{n,\alpha})
= \log(K_n/n^\alpha) + (\psi(K_n + \hat{\theta}_{n,\alpha}/\alpha) - \log K_n) - \alpha(\psi(n + \hat{\theta}_{n,\alpha}) - \log n) \to \log M_{\alpha \theta} \ (a.s.),
\]
thereby completing the proof.

**Remark 3.14.** Utilizing the bijective function $f_\alpha(z) : (-1, \infty) \to \mathbb{R}$ defined by (3.2), the asymptotic of $\hat{\theta}_{n,\alpha}$ can be rewritten as
\[
\hat{\theta}_{n,\alpha} \to \alpha \cdot f_\alpha^{-1}(\log M_{\alpha \theta}) \ (a.s.).
\]

Here, we visualize the limit law. We fix $\alpha = 0.5$ and $n = 2^{16}$. For each $\theta \in \{-0.2, 0.5, 10\}$, we sample $\hat{\theta}_{n,\alpha}$ independently 1000 times and plot the histogram in Figure 5. We see that $\hat{\theta}_{n,\alpha}$ is distributed around the true value $\theta$. See the Supplementary Material for additional experiments, where we try with various $\alpha$ and still observe similar phenomena. Therefore, theoretical analysis of $\alpha f_\alpha^{-1}(\log M_{\alpha \theta})$ is one of our future research topics.

### 3.4 $\alpha$ and $\theta$ are unknown

Herein, we consider the case where both $\alpha$ and $\theta$ are unknown. We define QMLE and SMLE and we will show that the assertion of Theorem 3.9 holds for QMLE and SMLE. Moreover, we derive their asymptotic errors to the MLE with $\theta$ known and compare them.
3.4.1 Quasi-Maximum Likelihood Estimator

Definition 3.3 (QMLE). Suppose \((\alpha, \theta)\) satisfies \(0 < \alpha < 1, \theta > -\alpha\). For all \(\theta^* \in (-\alpha, \infty)\), we define Quasi-Maximum Likelihood Estimator (QMLE) with plug-in \(\theta^*\), denoted by \(\hat{\alpha}_{n,\theta^*}\) and expressed as:

\[
\hat{\alpha}_{n,\theta^*} = \arg\max_{x \in (-\theta^* \vee 0, 1)} l_n(\alpha = x, \theta = \theta^*),
\]

where \(l_n(\alpha, \theta)\) is the log-likelihood expressed by (3.3).

If \(\theta^* = \theta\), \(\hat{\alpha}_{n,\theta^*}\) coincides with \(\hat{\alpha}_{n,\theta}\) in Definition 3.1. Here, we define the random function \(\hat{\Psi}_{n,\theta^*} : (-\theta^* \vee 0, 1) \to \mathbb{R}\) in the same way as (3.5) by

\[
\hat{\Psi}_{n,\theta^*}(x) := \frac{\partial_x l_n(x, \theta^*)}{K_n} = \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i}{\theta^* + ix} - \sum_{j=2}^{\infty} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i} - x.
\]

Then, by the same argument following (3.7), we see that \(\{1 < K_n < n\}\) and \(\{\theta^* < \Theta_n\}\) are the necessary and sufficient conditions for \(\hat{\alpha}_{n,\theta^*}\) to be the unique root of \(\hat{\Psi}_{n,\theta^*}\) on \((-\theta^* \vee 0, 1)\), and hence, \(\hat{\alpha}_{n,\theta^*}\) is the unique root of \(\hat{\Psi}_{n,\theta^*}\) on \((-\theta \vee 0, 1)\) with high probability.

Remark 3.15. The choice of \(\theta^*\) in Definition 3.3 is arbitrary under the restriction of \(\theta^* > -\alpha\). Considering \(\alpha\) is unknown, it is natural to set \(\theta^* \geq 0(> -\alpha)\). Conversely, if we take a too large value of \(\theta^*\), the probability of \(\{\theta^* < \Theta_n\}\) being not satisfied decays gradually. Therefore, setting \(\theta^* = 0\) is practical.

Lemma 3.16. For all \(\theta^* \in (-\alpha, \infty)\), \(\hat{\alpha}_{n,\theta^*} \to \alpha\) in probability.

Proof. Fix \(x \in (-\theta^* \vee 0, 1)\). From (3.17) and (3.8), the same argument in the derivation of (3.9) implies

\[
\hat{\Psi}_{n,\theta^*}(x) - \Psi(x) = -\frac{1}{x K_n} - \frac{\theta^*}{x K_n} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} - \sum_{j=2}^{\infty} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i} - x,
\]

where the first, second, and third terms are \(o_p(1)\) from \(K_n \to \infty\) (a.s.), \(K_n^{-1} \log K_n \to 0\) (a.s.), and Corollary 3.6.1, respectively. Therefore, we obtain \(\hat{\Psi}_{n,\theta^*}(x) \to \Psi(x)\) in probability. Then, the same argument in the proof of Lemma 3.7 with \(\theta\) replaced by \(\theta^*\) leads to the assertion.

Lemma 3.17. Suppose \(\theta^* \in (-\alpha, \infty)\), and we consider a closed subset \(I \subset (-\theta^* \vee 0, 1)\). Then, for \(\hat{\Psi}_{n,\theta^*}\) and \(\Psi\) defined by (3.17) and (3.8) respectively, \(\sup_{x \in I} |\hat{\Psi}_{n,\theta^*}(x) - \Psi(x)| \to 0\) (a.s.).
Sketch of proof. Differentiating both sides of (3.18), \(|\hat{\Psi}'_{n,\theta}(x) - \Psi'(x)|\) is bounded above by
\[
\frac{1}{K_n x^2} + \frac{2|\theta^*|}{x^2} \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} + \frac{(\theta^*)^2}{x^2} \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} + \frac{1}{x^2} \frac{1}{K_n} \sum_{i=1}^{K_n-1} \left( \frac{\psi_{n,j}}{K_n} - \rho_n(j) \right) \sum_{i=1}^{j-1} \frac{1}{(i-x)^2},
\]
for all \(x \in (-\theta^* \vee 0, 1)\). Then, the assertion easily follows by Lemma 3.5 and \(K_n \to \infty\) (a.s.). See the Supplementary Material for details.

**Corollary 3.17.1.** Let \((\tilde{\alpha}_n)_{n \geq 1}\) be a random series converging to \(\alpha\). Then, for any \(\theta^* \in (-\alpha, \infty)\), \(\Psi_{n,\theta^*}(\tilde{\alpha}_n) \to -I(\alpha) < 0\) in probability, where \(I(\alpha)\) is defined by (3.1).

**Proof.** \(\Psi'(\alpha) = -I(\alpha)\) by (B) of Lemma 3.4 implies
\[
\left| \hat{\Psi}'_{n,\theta^*}(\tilde{\alpha}_n) + I(\alpha) \right| \leq \left| \hat{\Psi}'_{n,\theta^*}(\tilde{\alpha}_n) - \Psi'(\tilde{\alpha}_n) \right| + |\Psi'(\tilde{\alpha}_n) - \Psi'(\alpha)|,
\]
where the second term is \(o_p(1)\) from the continuity of \(\Psi'\) on (0,1) (see (A) of Lemma 3.4) and \(\tilde{\alpha}_n - \alpha = o_p(1)\) by the assumption. As for the first term, we define \(\delta := 2^{-1} \min\{1 - \alpha, \alpha - (-\theta^* \vee 0)\}\) and \(B_\delta(\alpha) := [\alpha - \delta, \alpha + \delta]\). Note that \(B_\delta(\alpha) \subset (-\theta^* \vee 0, 1)\) and \(\tilde{\alpha}_n \in B_\delta(\alpha)\) with high probability. Then, for all \(\epsilon > 0\), Lemma 3.17 applied with \(I = B_\delta(\alpha)\) implies \(\Pr(|\Psi_{n,\theta^*}'(\tilde{\alpha}_n) - \Psi'(\tilde{\alpha}_n)| > \epsilon) \leq \Pr(\sup_{x \in B_\delta(\alpha)} |\Psi_{n,\theta^*}'(x) - \Psi'(x)| > \epsilon) \to 0\), and hence \(|\hat{\Psi}'_{n,\theta^*}(\tilde{\alpha}_n) - \Psi'(\tilde{\alpha}_n)| = o_p(1)\), thereby completing the proof.

**Theorem 3.18.** Suppose \(\theta^* \in (-\alpha, \infty)\). Then, for QMLE \(\hat{\alpha}_{n,\theta^*}\) in Definition 3.3, the assertion of Theorem 3.9 holds. Furthermore, for all \(\theta^*_1, \theta^*_2 \in (-\alpha, \infty)\), the asymptotic error between \(\hat{\alpha}_{n,\theta^*_1}\) and \(\hat{\alpha}_{n,\theta^*_2}\) is given by
\[
n^\alpha n \log n (\hat{\alpha}_{n,\theta^*_1} - \hat{\alpha}_{n,\theta^*_2}) = -\frac{\theta^*_1 - \theta^*_2}{\alpha I(\alpha) M_{\theta^*}} \text{ in probability. (3.19)}
\]

**Proof.** Suppose that (3.19) holds. Then,
\[
n^\alpha n \log n (\hat{\alpha}_{n,\theta^*_1} - \hat{\alpha}_{n,\theta^*_2}) + n^\alpha n \log n (\hat{\alpha}_{n,\theta} - \alpha) = O_p(n^{-\alpha/2} \log n) + n^\alpha n \log n (\hat{\alpha}_{n,\theta} - \alpha),
\]
and hence Theorem 3.9 leads to the stable convergence of \(\hat{\alpha}_{n,\theta^*}\) and suffices to show (3.19). Suppose (3.19) holds with \(\theta^*_2 = 0\) and general \(\theta^*_1 \in (-\alpha, \infty)\). Then, for all \(\theta^*_1, \theta^*_2 \in (-\alpha, \infty)\), \(n^\alpha \log n \cdot (\hat{\alpha}_{n,\theta^*_1} - \hat{\alpha}_{n,\theta^*_2})\) converges in probability as follows:
\[
n^\alpha n \log n (\hat{\alpha}_{n,\theta^*_1} - \hat{\alpha}_{n,\theta^*_2}) = \frac{n^\alpha}{n \alpha I(\alpha) M_{\theta^*_1}} = \frac{n^\alpha}{n \alpha I(\alpha) M_{\theta^*_2}} - \frac{n^\alpha}{n \alpha I(\alpha) M_{\theta^*_0}}.
\]
Therefore completing the proof. Therefore, it is sufficient to show (3.19) with \(\theta^*_1 = \theta^* \in (-\alpha, \infty)\) and \(\theta^*_2 = 0\). By applying Taylor’s theorem to \(\hat{\Psi}_{n,0}(\hat{\alpha}_{n,0}) = 0\), there exists \(\tilde{\alpha}_n\) that satisfies \(|\tilde{\alpha}_n - \alpha| \leq |\tilde{\alpha}_n - \alpha_0| \leq |\tilde{\alpha}_n - \alpha_0| \leq \psi_n,0(\tilde{\alpha}_n, \theta^*) = \hat{\Psi}_{n,0}(\tilde{\alpha}_n, \theta^*) - \Psi_{n,0}(\tilde{\alpha}_n, \theta^*) = (K_n \alpha_{\theta^*})^{-1} \sum_{i=1}^{K_n} \theta^*/(\theta^* + i\alpha_{\theta^*})\) by (3.17).

Note that \(\hat{\alpha}_n - \alpha = o_p(1)\) from the consistency of \(\hat{\alpha}_{n,\theta^*}\) by Lemma 3.16. Therefore, the following probability convergence holds:
\[
n^\alpha n \log n (\hat{\alpha}_{n,\theta^*} - \hat{\alpha}_{n,\theta^*_0}) = n^\alpha n \log n (\hat{\alpha}_{n,\theta^*} - \hat{\alpha}_{n,\theta^*_0}) = n^\alpha \log n (\hat{\alpha}_{n,\theta^*} - \hat{\alpha}_{n,\theta^*_0}) = \frac{1}{K_n} \sum_{i=1}^{K_n} \left( \frac{\psi_{n,j}}{K_n} - \rho_n(j) \right) \sum_{i=1}^{j-1} \frac{1}{(i-x)^2},
\]
where we use \(-\hat{\Psi}_{n,0}'(\tilde{\alpha}_n) \to I(\alpha)\) in probability (by Corollary 3.17.1 applied with \(\theta^* = 0\) and \(K_n/n^\alpha \to M_{\theta^*}\) (a.s.), as well as \(\sum_{i=1}^{K_n} (i + \theta^*/\alpha_{\theta^*})^{-1} = \psi(K_n + \theta^*/\alpha_{\theta^*}) - \psi(1 + \theta^*/\alpha_{\theta^*}) \to \log K_n + O_p(1)\) by Lemma 3.12 applied with \((\theta^*/\alpha_{\theta^*})/K_n = o_p(1)\). This concludes the proof.
3.4.2 Simultaneous Maximum Likelihood Estimator

**Definition 3.4** (SMLE). Suppose $0 < \alpha < 1 \theta > -\alpha$. For $(s, t)$ satisfying $0 < s < \alpha < t < 1$ \footnote{In practice, it suffices to set $(s, t) = (\epsilon, 1-\epsilon)$ for a sufficiently small $\epsilon > 0$ so that $\alpha$ is included in the interior of $[s, t]$.}, we define Simultaneous Maximum Likelihood Estimator (SMLE), denoted by $(\hat{\alpha}_n, \hat{\theta}_n)$, and expressed as:

$$(\hat{\alpha}_n, \hat{\theta}_n) := \arg\max_{x \in [s, t], y > -x} l_n(\alpha = x, \theta = y),$$

where $l_n(\alpha, \theta)$ is the log-likelihood expressed by (3.3).

We define random functions $\Phi_n(x, y)$ and $\Psi_n(x, y)$ on $\{x \in (0, 1), y > -x\}$ as:

$$\Phi_n(x, y) := \partial_y l_n(x, y) = \frac{\sum_{i=1}^{K-1} 1}{y+i} - \sum_{i=1}^{n-1} \frac{1}{y+i}, \quad (3.20)$$

$$\Psi_n(x, y) := K^{-1} \partial_y \Phi_n(x, y) = \frac{1}{K} \sum_{i=1}^{K-1} \frac{i}{y+ix} - \sum_{j=2}^{n} \sum_{i=1}^{n} \frac{1}{y+ix}. \quad (3.21)$$

In Proposition 3.22, we show that the solution of $\Phi_n(x, y) = \Psi_n(x, y) = 0$ uniquely exists on $\{x \in [s, t], y > -x\}$ and equals $(\hat{\alpha}_n, \hat{\theta}_n)$ in Definition 3.4 with high probability. Toward that, we show several lemmas.

**Lemma 3.19.** Suppose $1 < K < n$. Then, for all $x \in (0, 1)$, the solution of the random function $\Phi_{n,x}(y) := \Phi_n(x, y) = 0$ on $(-x, \infty)$ uniquely exists and $\Phi'_{n,x}(y)$ takes a negative value at the solution.

**Proof.** This lemma immediately follows from [1, Lemma 5.3] with $\alpha$ replaced by $x$. See the Supplementary Material.

Recall $\Pr\{1 < K_n < n\} = O(n^{-\alpha}) = o(1)$. Then, Lemma 3.19 implies, with high probability, that $l_n(x, y)$ is a unimodal function of $y \in (-x, \infty)$ and attains the global maxima at the unique solution of $\Phi_n(x, y) = 0$ for all $x \in (0, 1)$.

From now on, we assume $1 < K_n < n$. Herein, we denote the unique solution by $\hat{y}_n(x)$, i.e., $\hat{y}_n : (0, 1) \to (-x, \infty)$ is the random function which is uniquely determined by

$$\forall x \in (0, 1), \Phi_n(x, \hat{y}_n(x)) = 0, \quad (3.22)$$

where $\Phi_n(x, y)$ is given by (3.20). Then, $(\hat{\alpha}_n, \hat{\theta}_n)$ in Definition 3.4 can be written as

$$\hat{\alpha}_n = \arg\max_{x \in [s, t]} l_n(x, \hat{y}_n(x)), \quad \hat{\theta}_n = \hat{y}_n(\hat{\alpha}_n). \quad (3.23)$$

Let us define the random function $\hat{\Psi}_n(x)$ on $(0, 1)$ by

$$\hat{\Psi}_n(x) := \frac{1}{K_n} \cdot \frac{d}{dx} l_n(x, \hat{y}_n(x)) = \Phi_n(x, \hat{y}_n(x)) + K^{-1} \Phi_n(x, \hat{y}_n(x)) \cdot \hat{y}'_n(x) = \Psi_n(x, \hat{y}_n(x)), \quad (3.24)$$

where we used $\Phi_n(x, \hat{y}_n(x)) = 0$ and the fact that $\hat{y}_n(x)$ is differentiable by the implicit function theorem applied with $\Phi'_{n,x}(\hat{y}_n(x)) < 0$. Then, if the root of $\hat{\Psi}_n$ uniquely exists in $[s, t]$ and its derivative takes a negative at the points, the solution of $\Psi_n(x, y) = \Phi_n(x, y) = 0$ uniquely exists.
and equals to \((\hat{\alpha}_n, \hat{\theta}_n)\) in Definition 3.4. Therefore, it suffices to show a suitable convergence of \(\hat{\Psi}_n\) to \(\Psi\). Considering this, we define the random function \(\hat{z}_n : (0, 1) \to (-1, \infty)\) by

\[
\hat{z}_n : x \mapsto \hat{y}_n(x)/x \in (-1, \infty),
\tag{3.25}
\]

where \(\hat{y}_n(x)\) is characterized by (3.22). Then, \(\hat{\Psi}_n(x)\) can be written by

\[
\hat{\Psi}_n(x) = \frac{K_n - 1}{K_n x} - \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{\hat{z}_n(x)}{x \hat{z}_n(x) + i} - \sum_{j=1}^{n} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i - x} = \hat{\Psi}_{n,0}(x) - \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{\hat{z}_n(x)}{x \hat{z}_n(x) + i},
\tag{3.26}
\]

where \(\hat{\Psi}_{n,0}\) is given by (3.17) with \(\theta^* = 0\). See the Supplementary Material for the derivation of (3.26).

**Lemma 3.20.** Suppose \(1 < K_n < n\). For the random function \(\hat{z}_n : (0, 1) \to (-1, \infty)\) defined by (3.25), the following assertions hold.

(A) \(z'_n(x) = \sum_{i=1}^{n-1} i(x \hat{z}_n(x) + i)^{-2}/(-\sum_{i=1}^{n-1} 1/(x \hat{z}_n(x) + i) + 2 \sum_{i=1}^{n-1} x^2/(x \hat{z}_n(x) + i)^2) < 0\).

(B) \(|\hat{z}_n(x)| = O_p(n^{(\alpha-x)/(1-x)})\) if \(0 < x < \alpha\) and \(O_p(1)\) if \(\alpha \leq x < 1\).

(C) For all \(0 < \delta_n = o(1/\log n)\), \(\sup_{x \in [\alpha \pm \delta_n]} |\hat{z}_n(x)| = O_p(1)\) and \(\sup_{x \in [\alpha \pm \delta_n]} |f_\alpha(\hat{z}_n(x)) - \log(K_n/n^\alpha)| = O_p(1)\), where \(f_\alpha\) is defined in (3.2).

**Proof.** See the Supplementary Material.

**Lemma 3.21.** For \(\hat{\Psi}_n\) and \(\Psi\) defined by (3.24) and (3.8) respectively, the following asymptotics hold.

(A) \(\sup_{x \in I} |\hat{\Psi}_n(x) - \Psi(x)| = o_p(1)\) for any closed subset \(I \subset (0, 1)\).

(B) \(\sup_{x \in [\alpha \pm \delta_n]} |\hat{\Psi}'(x) - \Psi'(x)| = o_p(1)\) for all \(0 < \delta_n = o(1/\log n)\).

**Proof.** Proof of (A): Write \(I = [s, t]\). Note \(0 < s < t < 1\). By (3.8) and (3.26), \(|\hat{\Psi}_n(x) - \Psi(x)|\) is bounded above by

\[
\frac{1}{K_n x} + \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{|\hat{z}_n(x)|}{x \hat{z}_n(x) + i} + \sum_{j \geq 2} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{1}{i - \alpha} + \sum_{j \geq 2} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{x - \alpha}{(i - \alpha)(i + x)}.\]

Here, we show the uniform convergence on the closed subset \([s, t] \subset (0, 1)\) for each term. The proof for the first term is obvious, and the third term does not depend on \(x\) and \(o_p(1)\) from Corollary 3.6.1. The fourth term is uniformly bounded as

\[
\sup_{x \in I} \left| \sum_{j \geq 2} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{x - \alpha}{(i - \alpha)(i + x)} \right| \leq \sum_{j \geq 2} \left| \frac{S_{n,j}}{K_n} - p_\alpha(j) \right| \sum_{i=1}^{\infty} \frac{2}{(i - \alpha)(i + \alpha)},
\]

where the bound is \(o_p(1)\) by Lemma 3.5. As for the second term, note that

\[
\sup_{x \in I} \left| \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{|\hat{z}_n(x)|}{x \hat{z}_n(x) + i} \right| \leq \sup_{x \in [s, t]} |\hat{z}_n(x)| \sum_{i=1}^{n-1} \frac{1}{-t + i} = O_p(n^{-\alpha} \log n) \sup_{x \in [s, t]} |\hat{z}_n(x)|,
\tag{3.27}
\]

where we use \(x \hat{z}_n(x) > -x > -t > -1\). Note that (A) of Lemma 3.20 implies \(\sup_{x \in [s, t]} |\hat{z}_n(x)| \leq |\hat{z}_n(s)| + |\hat{z}_n(t)|\). From (B) of Lemma 3.20, we see that the upper bound is \(O_p(1)\) if \(\alpha \leq s < t\) and
where we define the random function

\( O_p(n^{(\alpha-s)/(1-s)}) \) if \( 0 < s < \alpha \). Since \((\alpha-s)/(1-s) - \alpha = -s(1-\alpha)/(1-s) < 0\), the right-hand side of (3.27) is anyway \( o_p(1) \). This completes the proof.

Proof of (B): We denote \([\alpha \pm \delta_n] \) by \( B_n \). Note that there exists a closed subset \( [s,t] \) such that \( B_n \subset [s,t] \subset (0,1) \) for sufficiently large \( n \) by \( \delta_n = o(1/\log n) = o(1) \). Then, using (3.26), \( \sup_{x \in B_n} |\Psi'(x) - \Psi'(x)| \) is bounded above by

\[
\sup_{x \in B_n} \left| \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{i}{(xz_n(x) + i)^2} - \frac{\hat{\Psi}(x)}{K_n} \sum_{i=1}^{n-1} \frac{i}{(xz_n(x) + i)^2} + \hat{\Psi}_n(x) - \Psi'(x) \right|,
\]

where the first term is \( o_p(1) \) owing to \( \sup_{x \in B_n} |z_n(x)| = O_p(1) \) by (C) of Lemma 3.20 and \( K_n \to \infty \) (a.s.), whereas the third term is \( o_p(1) \) by Lemma 3.17. In contrast, from (A) of Lemma 3.20, the second term is bounded above by

\[
\sup_{x \in B_n} \left| \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{i}{(xz_n(x) + i)^2} \right|^2 \cdot \sup_{x \in B_n} \left| \frac{1}{K_n} \sum_{i=1}^{n-1} \frac{x}{(xz_n(x) + i)^2} - \frac{1}{\inf_{x \in B_n} |J_n(x)|} \right| \leq \frac{1}{K_n} \left( \frac{n-1}{\inf_{x \in B_n} |J_n(x)|} \right)^{-1},
\]

where we define the random function \( J_n(x) := \sum_{i=1}^{K_n-1} (z_n(x) + i)^2 - \sum_{i=1}^{n-1} x^2/(xz_n(x) + i)^2 \). Therefore, it suffices to show \( \sup_{x \in B_n} |J_n(x)|^{-1} = O_p(1) \). Note that \( \psi^{(1)}(1+z) = \sum_{i=1}^{\infty} (i+z)^{-2} > 0 \) and \( f_{\alpha}(z) = \psi(1+z) - \alpha \psi(1+\alpha z) \) implies

\[
\sup_{x \in B_n} |J_n(x) + f_{\alpha}'(xz_n(x))| = \sup_{x \in B_n} |\psi^{(1)}(xz_n(x) + 1) - \psi^{(1)}(xz_n(x)) - x^2 \psi^{(1)}(xz_n(x) + n) + x^2 \psi^{(1)}(xz_n(x) + 1) + f_{\alpha}'(xz_n(x))| \leq \sup_{x \in B_n} |\psi^{(1)}(xz_n(x) + 1) - \psi^{(1)}(xz_n(x))| + \sup_{x \in B_n} |x^2 - 2\psi^{(1)}(xz_n(x) + 1) - \psi^{(1)}(xz_n(x) + 1)| + \sup_{x \in B_n} \alpha^2 |\psi^{(1)}(xz_n(x) + 1) - \psi^{(1)}(xz_n(x) + 1)| \leq \psi^{(1)}(K_n - 1) + \psi^{(1)}(n - 1) + 2\delta_n \psi^{(1)}(1 - t) + \alpha^2 \sup_{x \in B_n} |\psi^{(1)}(\alpha xz_n(x) + 1) - \psi^{(1)}(xz_n(x) + 1)| = o_p(1) + \alpha^2 \sup_{x \in B_n} |\psi^{(1)}(xz_n(x) + 1) - \psi^{(1)}(xz_n(x) + 1)|,
\]

where we utilize the fact that \( \psi^{(1)}(x) \) is positive and decreasing on \((0, \infty)\) with \( \lim_{x \to \infty} \psi^{(1)}(x) = 0 \).
For the second term, that the following holds:

\[
\sup_{x \in B_n} |\psi^{(1)}(\alpha \tilde{z}_n(x) + 1) - \psi^{(1)}(x \tilde{z}_n(x) + 1)| = \sup_{x \in B_n} \left| \frac{1}{(\alpha \tilde{z}_n(x) + i)^2} - \frac{1}{(x \tilde{z}_n(x) + i)^2} \right| = \sup_{x \in B_n} \left( \sum_{i=1}^{\infty} \frac{1}{(\alpha \tilde{z}_n(x) + i)^2} - \frac{1}{(x \tilde{z}_n(x) + i)^2} \right) \leq \sup_{x \in B_n} |x - \alpha| \sum_{i=1}^{\infty} \frac{2i |\tilde{z}_n(x)| + 2 |\tilde{z}_n(x)|^2}{(-\alpha + i)^2(-t + i)^2} \leq \sup_{x \in B_n} |x - \alpha| \left( \sup_{x \in B_n} |\tilde{z}_n(x)| + \sup_{x \in B_n} |\tilde{z}_n(x)|^2 \right) \cdot \sum_{i=1}^{\infty} \frac{2i}{(i - \alpha)^2(i - t)^2} = \delta_n O_p(1) O(1) = o_p(1),
\]

For these reasons, we have \(\sup_{x \in B_n} |J_n + f_n'(\tilde{z}_n(x))| = o_p(1)\). Conversely, \(f_n'(z) < 0\) on \(z \in (-1, \infty)\) (Lemma 3.2) and \(\tilde{z}_n'(x) < 0\) on \((0, 1)\) ((A) of Lemma 3.20) implies that \(f_n'(\tilde{z}_n'(x)) > 0\).

From this and \(B_n = [\alpha \pm \delta_n]\), we have

\[
\sup_{x \in B_n} |J_n(x)/f_n'(\tilde{z}_n(x)) - f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))| \leq |J_n(x)/f_n' \circ f_n^{-1}(\log(K_n/n^\alpha)) - f_n' \circ f_n^{-1}(\log(M_n))| = o_p(1),
\]

where we utilize the fact that both \(f_n'(\tilde{z}_n(\alpha \pm \delta_n))\) and \(f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))\) converge to \(f_n' \circ f_n^{-1}(\log(M_n))\) in probability (the former is from (C) of Lemma 3.20 and the latter follows from \(K_n/n^\alpha \to M_n\) (a.s.). Then we get \(\sup_{x \in B_n} |J_n(x)/f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))| = o_p(1)\), from which and \(1/f_n' \circ f_n^{-1}(\log(K_n/n^\alpha)) \to 1/f_n' \circ f_n^{-1}(\log(M_n)) > 0\) (a.s.) with \(f_n' > 0\) (see Lemma 3.2) we get

\[
\sup_{x \in B_n} \left| -J_n(x)/(f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))) + 1 \right| \to 0 \text{ in probability.}
\]

Therefore, with high probability, \(\sup_{x \in B_n} \left| -J_n(x)/(f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))) + 1 \right| < 1/2\). Note that this inequality implies \(\inf_{x \in B_n} \left| J_n(x)/f_n'(\tilde{z}_n(x)) \right| > 1/f_n' \circ f_n^{-1}(\log(K_n/n^\alpha))/2\), and hence \(1/\inf_{x \in B_n} |J_n(x)| < 2/f_n' \circ f_n^{-1}(\log(K_n/n^\alpha)) = O_p(1)\), which completes the proof.

**Proposition 3.22.** Let \((s, t)\) satisfy \(0 < s < \alpha < t < 1\). Then, for the random function \(\Phi_n\) and \(\Psi_n\) defined by (3.20) and (3.21), respectively, the solution of \(\Psi_n(x, y) = \Phi_n(x, y) = 0\) on \(\{x \in [s, t], y > -x\}\) uniquely exists and equals \(\text{SMLE} (\hat{\alpha}_n, \hat{\theta}_n)\) in Definition 3.4 with high probability.

**Proof.** By the argument just after (3.24), it suffices to show that the root of \(\Psi_n\) uniquely exists in \([s, t]\) whereas its derivative takes a negative value. For convenience purposes, we define the random set \(I_n := \{x \in [s, t] \mid \Psi_n(x) = 0\}\).

**Step 1.** \(\lim_{n \to \infty} \Pr(I_n = \emptyset) = 0\): Recall \(\Psi(t) < \Psi(\alpha) = 0 < \Psi(s)\) (see Lemma 3.4). Then, (A) of Lemma 3.21 implies \(\Pr(\tilde{\Psi}_n(s) < 0 \cup \tilde{\Psi}_n(t) > 0) \leq \Pr(\tilde{\Psi}(s) - \tilde{\Psi}_n(s) > \Psi(s) - \Psi(t)) \leq \Pr(\tilde{\Psi}(s) > \Psi(t)) \to 0\), and hence, \(\Pr(\tilde{\Psi}_n(s) > 0) \to 1\). Considering \(\Psi_n(x)\) is continuous, the Intermediate value theorem leads to assertion.

**Step 2.** \(\sup_{x \in I_n} |x - \alpha| = o_p(n^{-\alpha/4})\): First, we show \(\sup_{x \in I_n} |x - \alpha| = o_p(1)\). We take \(\epsilon > 0\) satisfying \(|\alpha - \epsilon| \subset [s, t]\) and define the positive constant \(\delta_\epsilon := (\Psi(\alpha - \epsilon) - \Psi(\alpha + \epsilon))/2\). Note that (A) of Lemma 3.21 implies \(\sup_{x \in [s, t]} |\tilde{\Psi}_n(x) - \Psi(x)| \leq \delta_\epsilon\) with high probability. Then, for all \(x \in [s, t] \subset [s, t]\), \(\Psi' < 0\) by (B) of Lemma 3.4 implies \(\tilde{\Psi}_n(x) - \Psi(x) - \delta_\epsilon > \Psi(\alpha - \epsilon) - \delta_\epsilon > \delta_\epsilon > 0\). Conversely, for all \(x \in [\alpha + \epsilon, t] \subset [s, t]\), the same argument implies \(\tilde{\Psi}_n(x) < \Psi(x) + \delta_\epsilon < \Psi(\alpha + \epsilon) + \delta_\epsilon < -\delta_\epsilon < 0\). For these reasons, it holds with high probability that \(\inf_{x \in [s, \alpha - \epsilon]} \tilde{\Psi}_n(x) > 0 > \sup_{x \in [\alpha + \epsilon, t]} \tilde{\Psi}_n(x)\). Therefore, we have \(\sup_{x \in I_n} |x - \alpha| \leq \epsilon\) with high probability, thereby completing the proof. Therefore, we have \(\sup_{x \in I_n} |x - \alpha| = o_p(1)\).

Next, we prove \(\sup_{x \in I_n} |x - \alpha| = o_p(n^{-\alpha/4})\). Considering Theorem 3.18 implies \(|x - \alpha| \leq |x - \alpha_n| + |\alpha_n - \alpha| = |x - \alpha_n| + O_p(n^{-\alpha/2})\), it suffices to show \(\sup_{x \in I_n} |x - \alpha_n| = o_p(n^{-\alpha/4})\).
We define the positive constant \( \delta := (1 - \alpha)/2 \land \alpha(1 - \alpha)/(4 - \alpha) \). Note that \( \sup_{x \in I_n} |x - \alpha| = o_p(1) \) and \( \alpha_{n,0} - \alpha = o_p(1) \) by Lemma 3.16 imply
\[
\hat{I}_n \subset B_\delta(\alpha) := [\alpha \pm \delta] \subset [3\alpha/(4 - \alpha), (1 + \alpha)/2] \subset (0, 1) \text{ and } \alpha_{n,0} \in B_\delta(\alpha) \quad (3.28)
\]
with high probability. Then, the monotonicity of \( \hat{z}_n(x) \) on \((0, 1)\) (from (A) of Lemma 3.20) and (B) of Lemma 3.20 applied with \((x - \alpha)/(1 - x)|_{x = 3\alpha/(4 - \alpha)} = \alpha/4 \) result in
\[
\sup_{x \in \hat{I}_n} |\hat{z}_n(x)| \leq |\hat{z}_n(3\alpha/(4 - \alpha))| + |\hat{z}_n((1 + \alpha)/2)| = O_p(n^{\alpha/4}) + O_p(1) = O_p(n^{\alpha/4}). \quad (3.29)
\]
Here, we fix \( x \in \hat{I}_n \). Then, by applying Taylor’s theorem to \( 0 = \hat{\Psi}_{n,0}(\alpha_{n,0}) \), there exists \( \bar{\alpha}(x) \) satisfying \( |\bar{\alpha}(x) - \alpha_{n,0}| \lor |\alpha - x| \leq |x - \alpha_{n,0}| \) and \( 0 = \hat{\Psi}_{n,0}(x) + \hat{\Psi}'_{n,0}(\bar{\alpha}(x)) \cdot (\alpha_{n,0} - x) \). Conversely, (3.26) imply \( \Psi_{n,0}(x) = \hat{\Psi}_{n,0}(x) - \hat{\Psi}(x) = K^{-1} \sum_{i=1}^{n-1} \hat{z}_i(x)/(x \hat{z}_i(x) + i) \). For these reasons, we have
\[
\forall x \in \hat{I}_n, \quad x - \alpha_{n,0} = \frac{\hat{\Psi}_{n,0}(x)}{\hat{\Psi}'_{n,0}(\bar{\alpha}(x))} = \frac{1}{K_n \cdot \hat{\Psi}'_{n,0}(\bar{\alpha}(x))} \sum_{i=1}^{n-1} \frac{\hat{z}_i(x)}{x \hat{z}_i(x) + i}, \quad (3.30)
\]
Note \( \alpha_{n}(x) \in B_\delta(\alpha) \) for all \( x \in \hat{I}_n \) by (3.28). Then, Lemma 3.17 applied with \( \theta^* = 0 \) implies
\[
\sup_{x \in \hat{I}_n} |\hat{\Psi}'_{n,0}(\bar{\alpha}(x)) - \Psi'(\bar{\alpha})| \leq \sup_{x \in B_\delta(\alpha)} |\hat{\Psi}'_{n,0}(\bar{\alpha})(x) - \Psi'(\bar{\alpha})| \rightarrow 0 \text{ in probability.} \quad (3.31)
\]
Here, let us take a positive constant \( C := -2^{-1} \cdot \max_{x \in B_\delta(\alpha)} \Psi'(x) > 0 \) (Note that \( C \) exists by the continuity of \( \Psi'(x) \) and \( \bar{\alpha}(x) \)). Then, \( \Pr(\sup_{x \in \hat{I}_n} |\hat{\Psi}_{n,0}(\bar{\alpha}(x)) - \Psi'(\bar{\alpha})| \leq C) \leq \Pr(\forall x \in \hat{I}_n, |\hat{\Psi}'_{n,0}(\bar{\alpha}(x))| > |\Psi'(\bar{\alpha})| - C) \leq \Pr(\inf_{x \in \hat{I}_n} |\hat{\Psi}_{n,0}(\bar{\alpha}(x))| > C) \), where the lower bound goes to 1 as \( n \rightarrow \infty \) by (3.31), and hence \( \inf_{x \in \hat{I}_n} |\hat{\Psi}'_{n,0}(\bar{\alpha}(x))| > C > 0 \) with high probability. Combining this with \( \hat{I}_n \subset B_\delta(\alpha) \), (29), (30), and \( \hat{z}_n(x) > -1 \), we have
\[
\sup_{x \in \hat{I}_n} |x - \alpha_{n,0}| = \sup_{x \in \hat{I}_n} \left| \frac{1}{K_n \cdot \hat{\Psi}'_{n,0}(\bar{\alpha}(x))} \sum_{i=1}^{n-1} \frac{\hat{z}_i(x)}{x \hat{z}_i(x) + i} \right| \leq \frac{1}{K_n C} \sum_{i=1}^{n-1} \frac{1}{(i + \Delta)} \leq O_p(n^{-\alpha}) |\log n| O_p(n^{\alpha/4}) = O_p(n^{-3\alpha/4} \log n) = o_p(n^{-\alpha/4}),
\]
thereby completing the proof.

**Step 3.** With high probability, \( \# \hat{I}_n = 1 \) and \( \hat{\Psi}'_{n,0}(\bar{\alpha}(x)) \) takes negative values at the unique element.

For the positive constant \( C = -2^{-1} \cdot \sup_{x \in B_\delta(\alpha)} \Psi'(x) \). \( \hat{I}_n \subset B_\delta(\alpha) \) implies \( \Pr(\sup_{x \in \hat{I}_n} \hat{\Psi}'_{n,0}(x) > -C) \leq \Pr(\forall x \in \hat{I}_n, \hat{\Psi}'_{n,0}(x) > \Psi'(x) + C) \leq \Pr(\sup_{x \in \hat{I}_n} |\hat{\Psi}'_{n,0}(x) - \Psi'(x)| > C) \), which is \( o(1) \) by Step 2 and (B) of Lemma 3.21. Therefore \( \hat{\Psi}'_{n,0}(x) \) is uniformly negative on \( \hat{I}_n \), and hence the cardinality of \( \hat{I}_n = \{ \hat{\Psi}(x) = 0 \} \) is at most 1 with high probability. Combining this and the step 1, the cardinality of \( \hat{I}_n \) must be 1 with high probability. This completes the proof.

**Theorem 3.23.** Let \( I(\alpha) \) be Fisher information of the Sibuya distribution defined by (3.1) and \( f_\alpha \) be the bivariate map defined by (3.2). Then, for SMLE \( (\hat{\alpha}_n, \hat{\theta}_n) \) in Definition 3.4, that the following holds:

(i) \( \sqrt{n^\alpha I(\alpha)} \cdot (\hat{\alpha}_n - \alpha) \rightarrow N/\sqrt{M_{\alpha \theta}} \mathcal{F}_\infty \)-stable, \( \theta \rightarrow \alpha \cdot f^{-1}_\alpha(\log M_{\alpha \theta}) \) in probability.

Note that \( M_{\alpha \theta} \sim \text{GMtL}(\alpha, \theta) \) and \( N \sim N(0, 1) \) is independent of \( \mathcal{F}_\infty \). Moreover, for all \( \theta^* \in (-\alpha, \infty) \), the asymptotic error with QMLE \( \alpha_{n^*}, \theta^* \) in Definition 3.3 is given by
\[
\frac{n^\alpha}{\log n} (\hat{\alpha}_n - \alpha) \rightarrow -\frac{\alpha \cdot f^{-1}_\alpha(\log M_{\alpha \theta}) - \theta^*}{\alpha I(\alpha) M_{\alpha \theta}} \text{ in probability.} \quad (3.32)
\]
Proof. Note that \( \hat{\alpha}_n \) is the unique root of \( \check{\Psi}_n \) and \( \hat{\theta}_n = \hat{\alpha}_n \check{\varepsilon}_n(\hat{\alpha}_n) \) with high probability by Proposition 3.22 and (3.23). In contrast, \( \hat{\alpha}_n \in [\alpha \pm n^{-\alpha/4}] \) with high probability (so especially \( \hat{\alpha}_n - \alpha = o_p(1) \)) by step 2 in the proof of Proposition 3.22. Then, (C) of Lemma 3.20 implies \( \check{\varepsilon}_n(\hat{\alpha}_n) \rightarrow f^{-1}_\alpha(\log M_{\alpha \theta}) \), and hence, \( \hat{\theta}_n \rightarrow \alpha f^{-1}_\alpha(\log M_{\alpha \theta}) \) in probability. Next, suppose (3.32), then Theorem 3.18 applied with \( \theta^* = 0 \) implies
\[
\sqrt{n^2} I(\alpha)(\hat{\alpha}_n - \alpha) = \sqrt{n^2} I(\alpha)(\hat{\alpha}_n - \hat{\alpha}_{n,0}) + \sqrt{n^2} I(\alpha)(\hat{\alpha}_{n,0} - \alpha) = O_p(n^{-\alpha/2} \log n) + n^{\alpha/2}(\hat{\alpha}_{n,0} - \alpha) \rightarrow N/\sqrt{M_{\alpha \theta}} \mathcal{F}_\infty \text{-stable,}
\]
which completes the proof of (i). Therefore, it suffices to show (3.32), however, it is sufficient to prove \( \theta^* = 0 \) owing to (3.19) in Theorem 3.18. Replacing \( x \) in (3.30) by \( \hat{\alpha}_n \), there exists \( \hat{\theta}_n \) satisfying \(|\alpha - \hat{\alpha}_n| \vee |\hat{\alpha}_n - \hat{\alpha}_{n,0}| < |\hat{\alpha}_n - \hat{\alpha}_{n,0}|, \) such that \( \hat{\theta}_n - \hat{\alpha}_{n,0} = (K_n \Psi_{n,0}(\hat{\alpha}_n))^{-1} \check{\varepsilon}_n(\hat{\alpha}_n) \sum_{i=1}^{n} (\hat{\theta}_n + i)^{-1}. \) Note that the consistency of \( \hat{\alpha}_n \) and \( \hat{\alpha}_{n,0} \) imply \( \hat{\alpha}_n \rightarrow \alpha \) in probability, and hence, Corollary 3.17.1 with \( \theta^* = 0 \) implies \( -\hat{\Psi}_{n,0}(\hat{\alpha}_n) \rightarrow I(\alpha) \) in probability. Moreover, Lemma 3.12 applied with \( \hat{\theta}_n/n = o_p(1) \) implies \( \sum_{i=1}^{n} (\hat{\theta}_n + i)^{-1} \approx \psi(n + \hat{\theta}_n) - \psi(1 + \hat{\theta}_n) = \log n + O_p(1) \), especially \( (\log n)^{-1} \sum_{i=1}^{n} (\hat{\theta}_n + i)^{-1} \rightarrow 1 \) in probability. Therefore, we have
\[
\frac{n^2}{\log n} (\hat{\alpha}_n - \hat{\alpha}_{n,0}) = \frac{1}{-\hat{\Psi}_{n,0}(\hat{\alpha}_n)} \frac{n^2}{K_n} \frac{-\check{\varepsilon}_n(\hat{\alpha}_n)}{\log n} \frac{1}{\sum_{i=1}^{n} \hat{\theta}_n + i} \frac{-f^{-1}_\alpha(\log M_{\alpha \theta})}{\alpha I(\alpha) M_{\alpha \theta}} \text{ in probability,}
\]
which completes the proof. \( \square \)

3.4.3 Comparison of QMLE and SMLE

Theorem 3.18 and Theorem 2.33 imply that Corollary 3.9.1 holds for \( \hat{\alpha}_{n,0} \) and \( \hat{\alpha}_n \). In contrast, their asymptotic error to \( \hat{\alpha}_{n,0} \) (the MLE of \( \alpha \) when \( \theta \) is known) differ in order \( n^{\alpha/2} \) as follows:

(i) \( \frac{n^\alpha}{\log n} (\hat{\alpha}_{n,0} - \hat{\alpha}_n) \rightarrow -\frac{\theta^* - \theta}{\alpha I(\alpha) M_{\alpha \theta}} \),

(ii) \( \frac{n^\alpha}{\log n} (\hat{\alpha}_n - \hat{\alpha}_{n,0}) \rightarrow -\frac{\alpha f^{-1}_\alpha(\log M_{\alpha \theta}) - \theta}{\alpha I(\alpha) M_{\alpha \theta}} \),

where the limit law of the error of (i) depends on “plugin error” \( \theta^* - \theta \) linearly whereas that of (ii) depends on \( \alpha f^{-1}_\alpha(\log M_{\alpha \theta}) - \theta \). Considering \( \alpha f^{-1}_\alpha(\log M_{\alpha \theta}) - \theta \) is distributed around \( \theta \) (see Remark 3.14), the error of \( \hat{\alpha}_{n,0} \) should be smaller than that of \( \hat{\alpha}_n \), if \( \theta^* \) is taken far away from \( \theta \) by the users. We show in Section 4 that those errors have a significant effect on the coverage and efficiency.

4 Numerical Experiment

Herein, we compare MLE \( \hat{\alpha}_{n,0} \) in Definition 3.1, QMLE \( \hat{\alpha}_{n,0} \) in Definition 3.3 with plug-in \( \theta^* = 0 \), and SMLE \( \hat{\alpha}_n \) in Definition 3.4 by efficiency and coverage. For each estimator \( \hat{\alpha}_n = \hat{\alpha}_{n,0}, \check{\varepsilon}_n, \hat{\alpha}_n \), we sample \( \hat{\alpha}_n \) \( 10^4 \) times independently and sequentially from \( n = 2^7 \) to \( 2^7 \). We approximate its efficiency by \( \text{MSE} \) of \( \hat{\alpha}_n \times K_n I(\alpha) \) and plot in Figure 6. Conversely, we plot the coverage of \( [\alpha_n + 1.96/\sqrt{K_n I(\alpha_n)}] \) in Figure 7, where we use (B) in Proposition 3.1 for the computation of \( I(\cdot) \) with \( j \) truncated at \( 10^6 \). We see that the efficiency and the coverage go to the theoretical limits 1 and 0.95 respectively as \( n \) increases. In contrast, when the plug-in error \( |0 - \theta| = |\theta| \) is large, the efficiency and the coverage of \( \hat{\alpha}_{n,0} \) is significantly small, whereas \( \hat{\alpha}_n \) is robust to the change of \( \theta \). These observations are consistent with the argument in Section 3.4.3.

5 Discussion and conclusions

We derived the asymptotic law of the MLE for the parameter \( (\alpha, \theta) \) of Ewens–Pitman Partition when \( 0 < \alpha < 1 \) and \( \theta > -\alpha \). In particular, we showed that the MLE for \( \alpha \) is consistent and
asymptotically mixed normal.

By the proposed confidence interval for $\alpha$, we can construct the hypothesis testing whether or not $\alpha$ is larger than a particular value that is included in $(0,1)$. In contrast, considering that the asymptotics of Ewens–Pitman Partition changes at $\alpha = 0$ (recall Section 2.3), a testing of $\alpha = 0$ or $0 < \alpha < 1$ is of more statistical interest. Note that the construction of the testing requires us to extend the asymptotic law of the MLE $(\hat{\alpha}_n, \hat{\theta}_n)$ from the parameter space $\{0 < \alpha < 1, \theta > -\alpha\}$ to $\{0 \leq \alpha < 1, \theta > -\alpha\}$, which includes $\alpha = 0$. Therefore, it is one of our future research topics to derive the asymptotic law of $(\hat{\alpha}_n, \hat{\theta}_n)$ under $\alpha = 0, \theta > 0$. We expect that there is an increasing series $a_n \to +\infty$ and a law $F$ such that $a_n \hat{\alpha}_n \to F$ and $(\theta^{-1} \log n)^{1/2} \cdot (\hat{\theta}_n - \theta) \to \mathcal{N}(0,1)$ weakly when $\alpha = 0$ and $\theta > 0$.

S1 Proof of Lemmas and Propositions

S1.1 Proof of Proposition 3.1
Recall that \( p_\alpha(j) \) is the density of Sibuya distribution expressed by
\[
\forall j \in \mathbb{N}, \quad p_\alpha(j) = \frac{\alpha \prod_{i=1}^{j-1}(i-\alpha)}{j!}.
\]
Therefore, \( I(\alpha) \) is calculated as
\[
I(\alpha) = -\sum_{j=1}^{\infty} p_\alpha(j) \partial_\alpha^2 \log p_\alpha(j) = \sum_{j=1}^{\infty} p_\alpha(j) \left( \frac{1}{\alpha^2} + \sum_{i=1}^{j-1} \frac{1}{(i-\alpha)^2} \right) = \frac{1}{\alpha^2} + \sum_{j=1}^{\infty} p_\alpha(j) \sum_{i=1}^{j-1} \frac{1}{(i-\alpha)^2},
\]
where the right-hand side is finite considering it is an expectation of a finite function of \( j \), and hence, we obtained (A). In contrast, by Fubini-Tonelli’s theorem, we get
\[
\sum_{j=1}^{\infty} p_\alpha(j) \sum_{i=1}^{j-1} \frac{1}{(i-\alpha)^2} = \sum_{i=1}^{\infty} \frac{1}{(i-\alpha)^2} \sum_{j=i+1}^{\infty} p_\alpha(j).
\]
Therefore, for the derivation of (B), it suffices to show the following equation for all \( i \in \mathbb{N} \):
\[
\sum_{j=i+1}^{\infty} p_\alpha(j) = \frac{i-\alpha}{\alpha} p_\alpha(i) \tag{S1.1}
\]
Note that (S1.1) holds for \( i = 1 \) by \( \sum_{j=2}^{\infty} p_\alpha(j) = 1 - p_\alpha(1) = 1 - \alpha = (1 - \alpha)/\alpha \). We assume (S1.1) for \( i = k \in \mathbb{N} \). Then, we have
\[
\sum_{j=k+2}^{\infty} p_\alpha(j) = \sum_{j=k+1}^{\infty} p_\alpha(j) - p_\alpha(k+1) = \frac{k-\alpha}{\alpha} p_\alpha(k) - p_\alpha(k+1) = \frac{k+1-\alpha}{\alpha} p_\alpha(k+1),
\]
and hence (S1.1) holds for \( i = k + 1 \). Therefore, (S1.1) holds for all \( i \in \mathbb{N} \) by induction.

As for the continuity of \( I(\alpha) \), it suffices to show the uniform convergence of \( I(\alpha) \) on \( K \) for any closed subset \( K = [s,t] \in (0,1) \). As we have just shown, \( I(\alpha) \) can be written as
\[
I(\alpha) = \frac{1}{\alpha^2} + \sum_{j=1}^{\infty} \frac{p_\alpha(j)}{\alpha(i-\alpha)}.
\]
Considering \( p_\alpha(j)/\alpha = (\prod_{i=1}^{j-1}(i-\alpha))/j! \) is non-increasing on \([s,t]\), we have
\[
\forall j \in \mathbb{N}, \quad \sup_{\alpha \in K} \left| p_\alpha(j) \frac{1}{\alpha(j-\alpha)} \right| \leq \sup_{\alpha \in K} \frac{p_\alpha(j)}{\alpha} \cdot \sup_{\alpha \in K} \frac{1}{j-\alpha} = \frac{p_\alpha(j)}{s} \cdot \frac{1}{j-t} \leq \frac{p_\alpha(j)}{s(1-t)},
\]
and \( \sum_{j=1}^{\infty} p_\alpha(j)/(s(1-t)) = 1/(s(i-t)) < +\infty \). Therefore, Weierstrass M-test implies that \( I(\alpha) \) converges uniformly on \( K \). This completes the proof.
S1.2 Proof of Lemma 3.2

Recall that \( f_\alpha : (-1, \infty) \to \mathbb{R} \) is defined by

\[
\forall z \in (-1, \infty), \quad f_\alpha(z) := \psi(1 + z) - \alpha \psi(1 + \alpha z),
\]

where \( \psi(z) = \Gamma'(z)/\Gamma(z) \) is the digamma function. Note that \( \lim_{z \to 0^+} \psi(z) = -\infty \) implies

\[
\lim_{z \to -1^+} f_\alpha(z) = \lim_{z \to -1^+} \psi(1 + z) - \alpha \psi(1 - \alpha) = -\infty,
\]

whereas \( \psi(z) = \log z + o(1) \) for large \( z > 0 \) (see, for example, [20, Section 6]) yields

\[
f_\alpha(z) = \log z - \alpha \log(\alpha z) + o(1) = (1 - \alpha) \log z + O(1) \quad \text{as} \quad z \to +\infty,
\]

and hence \( \lim_{z \to +\infty} f_\alpha(z) = +\infty \). In contrast, the infinite series expression of the trigamma function

\[
\psi^{(1)}(1 + z) = \sum_{i=1}^{\infty} (i + z)^{-2}
\]

for all \( z > -1 \) implies

\[
f'_\alpha(z) = \psi^{(1)}(1 + z) - \alpha^2 \psi^{(1)}(1 + \alpha z) = \sum_{i=1}^{\infty} \{(i + z)^{-2} - \alpha^2(i + \alpha z)^{-2}\}
\]

\[
= \sum_{i=1}^{\infty} \{(i + z)^{-2} - (i/\alpha + z)^{-2}\} \geq \sum_{i=1}^{\infty} \{(i + z)^{-2} - (i + z)^{-2}\} = 0.
\]

Therefore, \( f_\alpha(z) \) is bijective from \((-1, \infty)\) to \( \mathbb{R} \). Moreover, \( \psi^{(2)}(1 + z) = -2 \sum_{i=1}^{\infty} (i + z)^{-2} \) leads to

\[
f''_\alpha(z) = \psi^{(2)}(1 + z) - \alpha^3 \psi^{(2)}(1 + \alpha z) = -2 \sum_{i=1}^{\infty} \{(i + z)^{-3} - \alpha^3(i + \alpha z)^{-3}\} < 0,
\]

thereby completing the proof.

S1.3 Proof of Proposition 3.3

Recall that Ewens–Pitman partition has the following log-likelihood:

\[
l_n(\alpha, \theta) = \sum_{i=1}^{K_n} \log(\theta + i \alpha) - \sum_{i=1}^{n-1} \log(\theta + i) + \sum_{j=2}^{n} \sum_{i=1}^{j-1} \log(i - \alpha).
\]

Note

\[
\partial_{\theta}^2 l_n(\alpha, \theta) = -\sum_{i=1}^{K_n-1} \frac{1}{(\theta + i \alpha)^2} + \sum_{i=1}^{n-1} \frac{1}{(\theta + i)^2}. \tag{S1.2}
\]

Considering \( \sum_{i=1}^{K_n-1} (\theta + i \alpha)^{-2} \) is a strictly increasing function of \( K_n \) and \( K_n \) is a non-decreasing random variable, Monotone convergence theorem leads to

\[
\mathbb{E} \left[ \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i \alpha)^2} \right] \to \sum_{i=1}^{\infty} \frac{1}{(\theta + i \alpha)^2} < +\infty. \tag{S1.3}
\]

Then, (S1.2), (S1.3) and the infinite series expression of the trigamma function \( \psi^{(1)}(1 + z) = \sum_{i=1}^{\infty} (i + z)^{-2} \) for all \( z > -1 \) result in

\[
I^{(n)}_{\theta \theta} = \mathbb{E}[\partial_{\theta}^2 l_n(\alpha, \theta)] = \mathbb{E} \left[ \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i \alpha)^2} \right] - \sum_{i=1}^{n-1} \frac{1}{(\theta + i)^2} \to \sum_{i=1}^{\infty} \frac{1}{(\theta + i)^2} - \sum_{i=1}^{\infty} \frac{1}{(\theta + i)^2}
\]

\[
= \frac{1}{\alpha^2} \left( \sum_{i=1}^{\infty} \frac{1}{(i + \theta/\alpha)^2} - \sum_{i=1}^{\infty} \frac{\alpha^2}{(i + \theta)^2} \right) = \frac{\psi^{(1)}(1 + \theta/\alpha) - \alpha^2 \psi^{(1)}(1 + \alpha \cdot \theta/\alpha)}{\alpha^2} = \alpha^{-2} f'_\alpha(\theta/\alpha) < +\infty,
\]

\[
= \alpha^{-2} f'_\alpha(\theta/\alpha) < +\infty.
\]
thereby completing the proof for $I^{(n)}_{\theta \alpha}$.

Next, we derive the leading term for $I^{(n)}_{\alpha \alpha}$. Considering $l_n(\alpha, \theta)$ is the log-likelihood, $E[\partial_\theta l_n(\alpha, \theta)] = 0$ holds, which is equivalent to

$$
E \left[ \sum_{i=1}^{K_n-1} \frac{1}{\theta + i\alpha} \right] - \sum_{i=1}^{n-1} \frac{1}{\theta + i} = 0. 
$$

(S1.4)

In contrast,

$$
\partial_\theta \partial_\alpha l_n(\alpha, \theta) = - \sum_{i=1}^{K_n-1} \frac{i}{(\theta + i\alpha)^2} = - \frac{1}{\alpha} \sum_{i=1}^{K_n-1} \frac{1}{\theta + i\alpha} + \theta \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i\alpha)^2}.
$$

Thus, (S1.3) and (S1.4) yield

$$
I^{(n)}_{\theta \alpha} = - E[\partial_\theta \partial_\alpha l_n(\alpha, \theta)] = \frac{1}{\alpha} E \left[ \sum_{i=1}^{K_n-1} \frac{1}{\theta + i\alpha} \right] - \theta \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i\alpha)^2}
$$

$$
= \frac{1}{\alpha} \sum_{i=1}^{n-1} \frac{1}{\theta + i} + O(1) = \alpha^{-1} \log n + O(1),
$$

which completes the proof for $I^{(n)}_{\theta \alpha}$.

Finally, we derive the leading term for $I^{(n)}_{\alpha \alpha}$. Note

$$
\partial_\alpha^2 l_n(\alpha, \theta) = - \sum_{i=1}^{K_n-1} \frac{i^2}{(\theta + i\alpha)^2} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{(i - \alpha)^2},
$$

and

$$
\forall i \in \mathbb{N}, \quad \frac{i^2}{(\theta + i\alpha)^2} = \frac{1}{\alpha^2} - \frac{2\theta}{\alpha^2 \theta + i\alpha} + \frac{\theta^2}{\alpha^2(\theta + i\alpha)^2}.
$$

Then, from (S1.3), (S1.4), we have

$$
I^{(n)}_{\alpha \alpha} = - E[\partial_\alpha^2 l_n(\alpha, \theta)] = E \left[ \sum_{i=1}^{K_n-1} \frac{i^2}{(\theta + i\alpha)^2} \right] + \sum_{j=2}^{n} E[S_{n,j}] \sum_{i=1}^{j-1} \frac{1}{(i - \alpha)^2}
$$

$$
= \frac{E[K_n]}{\alpha^2} - \frac{2\theta}{\alpha^2} E \left[ \sum_{i=1}^{K_n-1} \frac{1}{\theta + i\alpha} \right] + \frac{\theta^2}{\alpha^2} E \left[ \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i\alpha)^2} \right] + \sum_{j=2}^{n} E[S_{n,j}] \sum_{i=1}^{j-1} \frac{1}{(i - \alpha)^2}
$$

$$
= \frac{1}{\alpha^2} E[K_n] + \sum_{j=2}^{n} E[S_{n,j}] \sum_{i=1}^{j-1} \frac{1}{(i - \alpha)^2} - \frac{2\theta}{\alpha^2} \sum_{i=1}^{n-1} \frac{1}{\theta + i} + \frac{\theta^2}{\alpha^2} E \left[ \sum_{i=1}^{K_n-1} \frac{1}{(\theta + i\alpha)^2} \right] - \frac{1}{\alpha^2}
$$

$$
= \frac{E[K_n]}{\alpha^2} + \sum_{j=2}^{n} E[S_{n,j}] \sum_{i=1}^{j-1} \frac{1}{(i - \alpha)^2} + O(\log n).
$$

Here, we define $X_n := \alpha^{-2} K_n + \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} (i - \alpha)^{-2}$. Considering $K_n = \sum_{j=1}^{n} S_{n,j}$, we get

$$
I^{(n)}_{\alpha \alpha} = E[X_n] + O(\log n),
$$

(S1.5)

$$
0 \leq X_n = \sum_{j=1}^{n} S_{n,j} \left( \frac{1}{\alpha^2} + \sum_{i=0}^{j-1} \frac{1}{(i - \alpha)^2} \right) \leq \sum_{j=1}^{n} S_{n,j} \sum_{i=0}^{j-1} \frac{1}{(i - \alpha)^2} \leq \sum_{j=1}^{n} S_{n,j} \sum_{i=0}^{\infty} \frac{1}{(i - \alpha)^2} = K_n C_\alpha,
$$

(S1.6)
where we define the positive constant $C_\alpha := \sum_{i=0}^{\infty} (i - \alpha)^{-2}$. Then, Corollary 3.5.1 applied with $g(j) = \sum_{i=0}^{j-1} (i - \alpha)^{-2}$, (A) of Proposition 3.1, and $K_n/n^\alpha \rightarrow M_{\alpha \theta}$ (a.s.) where $M_{\alpha \theta} \sim \text{GMtL}(\alpha, \theta)$ result in

$$X_n = \frac{K_n}{n^\alpha} \sum_{j=1}^{\infty} \frac{1}{K_n} \sum_{i=0}^{j-1} \frac{1}{(i - \alpha)^2} \rightarrow M_{\alpha \theta} \sum_{j=1}^{\infty} \frac{1}{K_n} \sum_{i=0}^{j-1} \frac{1}{(i - \alpha)^2}$$

$$= M_{\alpha \theta} \left( \frac{1}{\alpha^2} + \sum_{j=2}^{\infty} \frac{1}{K_n} \sum_{i=0}^{j-1} \frac{1}{(i - \alpha)^2} \right) = M_{\alpha \theta} I(\alpha) \text{ (a.s.)}. \quad (S1.7)$$

Conversely, considering $K_n/n^\alpha \rightarrow M_{\alpha \theta}$ in mean by (A) of Lemma 2.1, (S1.6), (S1.7), and the dominated convergence yield

$$n^{-\alpha} E[X_n] = E[n^{-\alpha} X_n] \rightarrow E[M_{\alpha \theta} I(\alpha)] = E[M_{\alpha \theta}] I(\alpha). \quad (S1.8)$$

Therefore, from (S1.5) and (S1.8), we have

$$n^{-\alpha} I(\alpha) = n^{-\alpha} E[X_n] + O(n^{-\alpha} \log n) \rightarrow E[M_{\alpha \theta}] I(\alpha),$$

which completes the proof for $I(\alpha)$.

### S1.4 Derivation of (3.7)

First, we prove the sufficiency. Recall that $\hat{\Psi}_{n, \theta} : (-\theta \lor 0, 1) \rightarrow \mathbb{R}$ is defined by

$$\forall x \in (-\theta \lor 0, 1), \hat{\Psi}_{n, \theta}(x) := \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i}{\theta + ix} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{i - x}. $$

Considering $K_n < n$ is equivalent to $\sum_{j=2}^{\infty} S_{n,j} > 0$, $\hat{\Psi}_{n, \theta}(x)$ can be expressed as

$$\hat{\Psi}_{n, \theta}(x) = -\frac{1}{1 - x} \sum_{j=2}^{n} S_{n,j} + \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i}{\theta + ix} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{i - x},$$

where the first term goes to $-\infty$ whereas the others converge to a finite value as $x \rightarrow 1-$, and hence, $\lim_{x \rightarrow 1-} \hat{\Psi}_{n, \theta}(x) < 0$.

As for $\lim_{x \rightarrow (-\theta \lor 0, 1)} \hat{\Psi}_{n, \theta}(x) > 0$, we divide the proof into the two cases $\{\theta > 0\}$ and $\{\theta < 0\}$. In the former case, it holds that

$$\lim_{x \rightarrow (-\theta \lor 0, 1)+} \hat{\Psi}_{n, \theta}(x) = \hat{\Psi}_{n, \theta}(0) = \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i}{\theta} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{i} = \frac{K_n - 1}{2\theta} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{i},$$

where we used $\sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} i^{-1} > \sum_{j=2}^{n} S_{n,j} > 0$ and the assumption $\Theta_n > \theta$. In contrast, if $-\alpha < \theta \leq 0$, $-\theta \lor 0 = -\theta$. Then, $1 < K_n$ gives

$$\hat{\Psi}_{n, \theta}(x) = \frac{1}{K_n} \frac{1}{\theta + x} + \frac{1}{K_n} \sum_{i=2}^{K_n-1} \frac{i}{\theta + ix} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{i - x},$$

28
where the first term goes to $+\infty$ while the other terms converge to finite values as $x \to (-\theta)^+$, and hence, $\lim_{x \to (-\theta)^+} \hat{\Psi}_{n,\theta}(x) > 0$.

Finally, we prove the necessity. However, this is obvious from the previous argument. Suppose $K_n = 1$, which is equivalent to $S_{n,n} = 1$. Then, $\Psi_{n,\theta}(x) = -n \sum_{i=1}^{n-1} \frac{(i - x)^{-1}}{i}$ for all $x \in (-\theta \vee 0, 1)$, so it has no roots on $(-\theta \vee 0, 1)$. Conversely, if $K_n = n$, i.e., $S_{n,1} = n$, $\hat{\Psi}_{n,\theta}(x) = n^{-1} \sum_{i=1}^{n-1} \frac{i}{(x + ix)} > 0$ for all $x \in (-\theta \vee 0, 1)$, and hence it has no roots. Finally, we assume that $1 < K_n < n$ but $\theta \geq \Theta_n$, which implies $\theta$ must be positive. Considering $\hat{\Psi}_{n,\theta}$ is decreasing, it holds that

$$\forall x \in (-\theta \vee 0, 1) = (0, 1), \quad \hat{\Psi}_{n,\theta}(x) < \hat{\Psi}_{n,\theta}(0) = \frac{\sum_{j=2}^{n} S_{n,j}}{\theta} \sum_{i=1}^{j-1} \frac{i^{-1}}{(\Theta_n - \theta)} \leq 0,$$

and hence it has no roots.

### S1.5 Proof of Lemma 3.4

Fix $\alpha \in (0, 1)$. Recall that $\Psi : (0, 1) \to \mathbb{R}$ is defined by

$$\forall x \in (0, 1), \quad \Psi(x) := \Psi(x; \alpha) = \frac{1}{x} - \sum_{j=1}^{\infty} p_{\alpha}(j) \sum_{i=1}^{j-1} \frac{1}{i - x}.$$

Note that the pointwise convergence of $\Psi(x)$ for each $x \in (0, 1)$ is obvious from the following three facts:

- $p_{\alpha}(j) = O(j^{-(1+\alpha)})$ (see Section 2.1)
- $\sum_{i=1}^{j-1} \frac{1}{i - x} \sim \log j$ for all $x \in (0, 1)$.
- $\int_{1}^{\infty} \log x \cdot x^{-1+\alpha} \, dx = \alpha^{2} < +\infty$.

First, we prove (A) and (B). Let $K = [s, t] \subset (0, 1)$ be any closed subset. Then,

$$\sup_{x \in K} \left| \frac{d}{dx} \sum_{i=1}^{j-1} \frac{1}{i - x} \right| = \sup_{x \in K} \sum_{i=1}^{j-1} \frac{1}{(i - x)^2} < \sum_{i=1}^{\infty} \frac{1}{(i - t)^2} := C,$$

and $\sum_{i=1}^{\infty} p_{\alpha}(j) C = C < +\infty$. Therefore, Weierstrass’s M-test implies the uniform convergence of $\Psi'(x)$ on $K$. Considering $K$ is any closed subset of $(0, 1)$, $\Psi'(x)$ converges compactly on $(0, 1)$, which implies $\Psi$ is class $C^1$ on $(0, 1)$ and we can interchange differential and infinite series so that

$$\Psi'(x) = -\frac{1}{x^2} - \sum_{j=1}^{\infty} p_{\alpha}(j) \sum_{i=1}^{j-1} \frac{1}{(i - x)^2} < 0.$$

Note that $\Psi'(x = \alpha) = -I(\alpha)$ is obvious from the above expression and formula (A) of Proposition 3.1.

As for (C), recall that $p_{\alpha}(j)$ is a probability mass function on $N$ so that it satisfies $\sum_{j=1}^{\infty} p_{\alpha}(j) = 1$. The differentiation of the left and right side by $\alpha$ leads to $\frac{d}{d\alpha} \sum_{n=1}^{\infty} p_{\alpha}(j) = 0$. Conversely, the definition of $p_{\alpha}(j)$ implies

$$\sum_{j=1}^{\infty} \frac{d}{d\alpha} p_{\alpha}(j) = \sum_{j=1}^{\infty} p_{\alpha}(j) \left( \frac{1}{\alpha} - \sum_{i=1}^{j-1} \frac{1}{i - \alpha} \right) = \frac{1}{\alpha} - \sum_{j=2}^{\infty} p_{\alpha}(j) \sum_{i=1}^{j-1} \frac{1}{i - \alpha} = \Psi(\alpha),$$

29
so it is sufficient to prove \( \frac{d}{d\alpha} \sum_{n=1}^{\infty} p_{\alpha}(j) = \sum_{n=1}^{\infty} \frac{d}{d\alpha} p_{\alpha}(j) \). The sufficient conditions for this is again the compact convergence of \( \sum_{j=1}^{\infty} \frac{d}{d\alpha} p_{\alpha}(j) \) on \((0, 1)\), i.e. the uniform convergence of \( \sum_{j=1}^{\infty} \frac{d}{d\alpha} p_{\alpha}(j) \) on \( K \) for any closed interval \( K = [s, t] \subset (0, 1) \). Note that \( \alpha^{-1} p_{\alpha}(j) = \prod_{i=1}^{j-1} (i - \alpha)/j! \) is non-increasing function on \((0, 1)\) for all \( j \in \mathbb{N} \). Then, we have

\[
\sup_{\alpha \in [s, t]} \left| \frac{d}{d\alpha} p_{\alpha}(j) \right| = \sup_{\alpha \in [s, t]} \left| \frac{p_{\alpha}(j)}{\alpha} \right| \left( 1 - \sum_{i=1}^{j-1} \frac{1}{i - \alpha} \right) \leq \sup_{\alpha \in [s, t]} \left( \frac{p_{\alpha}(j)}{\alpha} \right) \left( 1 + \sum_{i=1}^{j-1} \frac{\alpha}{i - \alpha} \right) = M_{j}^{s,t},
\]

and

\[
\sum_{j=1}^{\infty} M_{j}^{s,t} = \sum_{j=1}^{\infty} \frac{p_{\alpha}(j)}{s} \left( 1 + t - \sum_{i=1}^{j-1} \frac{1}{i - t} \right) = \frac{1}{s} + \frac{t}{s} \sum_{j=1}^{\infty} \sum_{i=1}^{j-1} \frac{1}{i - t} < +\infty,
\]

where the existence of the right hand side follows by the same argument in that of \( \Psi(x) \). Thus, Weierstrass’s M-test implies that \( \sum_{j=1}^{\infty} \frac{d}{d\alpha} p_{\alpha}(j) \) converges uniformly on \([s, t]\), completing the proof.

### S1.6 Proof of Lemma 3.5

We define \( N_{j} := \{ \lim_{n \to \infty} S_{n,j} / K_n \neq p_{\alpha}(j) \} \) and \( \mathcal{N} := \bigcup_{j=1}^{\infty} N_{j} \). Considering \( \Pr(N_{j}) = 0 \) by (B) of Lemma 2.1, \( \Pr(\mathcal{N}) = \Pr(\bigcup_{j=1}^{\infty} N_{j}) \leq \sum_{j=1}^{\infty} \Pr(N_{j}) = 0 \), i.e. \( \mathcal{N} \) is null set. We fix \( \omega \in \mathcal{N}^{c} \). Note

\[
\left| \frac{S_{n,j}}{K_n} (\omega) - p_{\alpha}(j) \right| \leq \frac{S_{n,j}}{K_n} (\omega) + p_{\alpha}(j), \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} (\omega) + p_{\alpha}(j) \right) = 2,
\]

so Fatou’s lemma implies

\[
2 - \lim \sup_{n \to \infty} \sum_{j=1}^{\infty} \left| \frac{S_{n,j}}{K_n} (\omega) - p_{\alpha}(j) \right| = \lim \inf_{n \to \infty} \left( 2 - \sum_{j=1}^{\infty} \left| \frac{S_{n,j}}{K_n} (\omega) - p_{\alpha}(j) \right| \right)
\]

\[
= \lim \inf_{n \to \infty} \left\{ \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} (\omega) + p_{\alpha}(j) - \left| \frac{S_{n,j}}{K_n} (\omega) - p_{\alpha}(j) \right| \right) \right\}
\]

\[
\geq \sum_{j=1}^{\infty} \left( \lim \inf_{n \to \infty} \left( \frac{S_{n,j}}{K_n} (\omega) + p_{\alpha}(j) - \left| \frac{S_{n,j}}{K_n} (\omega) - p_{\alpha}(j) \right| \right) \right) = \sum_{j=1}^{\infty} (2p_{\alpha}(j) + 0) = 2.
\]

Subtracting 2 from the left and right side, we get \( \lim \sup_{n \to \infty} \sum_{j=1}^{\infty} \left| S_{n,j} / K_n (\omega) - p_{\alpha}(j) \right| = 0 \), that is, \( \lim_{n \to \infty} \sum_{j=1}^{\infty} \left| S_{n,j} / K_n (\omega) - p_{\alpha}(j) \right| = 0 \). Considering \( \omega \in \mathcal{N}^{c} \) and \( \mathcal{N} \) is a null set, the assertion holds.
S1.7 Proof of Lemma 3.17

For all $x \in (-\theta \lor 0, 1)$, it holds that

\[
\Psi_n^\prime(x) = -\frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i^2}{(\theta^* + ix)^2} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{(i-x)^2}
\]

\[
= -\frac{K_n - 1}{K_n x^2} + \frac{2\theta}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} - \frac{(\theta^*)^2}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} - \sum_{j=2}^{n} S_{n,j} \sum_{i=1}^{j-1} \frac{1}{(i-x)^2}
\]

\[
= \Psi(x) + \frac{1}{K_n x^2} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} - \frac{(\theta^*)^2}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} - \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{1}{(i-x)^2}
\]

where we used (B) of Lemma 3.4 for the third equality. Then, we get

\[
\sup_{x \in I} \left| \Psi_n^\prime(x) - \Psi(x) \right| \leq \sup_{x \in I} \left( \frac{1}{K_n x^2} + \frac{2\theta}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} - \frac{(\theta^*)^2}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} + \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{1}{(i-x)^2} \right).
\]

Write $I$ by $I = [s, t]$. Note $(-\theta^* \lor 0) < s < t < 1$. Then, each term converges to 0 (a.s.) as follows:

\[
0 \leq \sup_{x \in I} \frac{1}{K_n x^2} \leq \frac{1}{K_n s^2} \to 0,
\]

\[
0 \leq \sup_{x \in I} \left( \frac{2\theta}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{\theta^* + ix} - \frac{(\theta^*)^2}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} \right) \to 0,
\]

\[
0 \leq \sup_{x \in I} \left( \frac{(\theta^*)^2}{x^2} \sum_{i=1}^{K_n-1} \frac{1}{(\theta^* + ix)^2} \right) \to 0,
\]

\[
0 \leq \sup_{x \in I} \left( \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \sum_{i=1}^{j-1} \frac{1}{(i-x)^2} \right) \leq \sum_{i=1}^{\infty} \frac{1}{(i-t)^2} \sum_{j=1}^{\infty} \left( \frac{S_{n,j}}{K_n} - p_\alpha(j) \right) \to 0,
\]

where we used $K_n \to \infty$ (a.s.) and $\sum_{j=1}^{\infty} |S_{n,j}/K_n - p_\alpha(j)| \to 0$ (a.s.) (by Lemma 3.5). This completes the proof.

S1.8 Proof of Lemma 3.19

The following proof is obtained by [1, Lemma 5.3] with $\alpha$ replaced by $x \in (0, 1)$. We fix $x \in (0, 1)$. Recall that $\Phi_n : (-\infty, \infty) \to \mathbb{R}$ is the function defined by

\[
\forall y > -x, \quad \Phi_n(x, y) := \Phi_n(x, y) = \sum_{i=1}^{K_n-1} \frac{1}{y + ix} - \sum_{i=1}^{n-1} \frac{1}{y + i}
\]

(S1.9)

Then, $1 < K_n$ implies

\[
\lim_{y \to -x^+} \Phi_n(x, y) = \lim_{y \to -x^+} \frac{1}{y + x} + \sum_{i=2}^{n-1} \frac{1}{(i-1)x} - \sum_{i=1}^{n-1} \frac{1}{-x + i} = +\infty.
\]
and $K_n < n$ yields
\[
\hat{\Phi}_{n,x}(y) = \sum_{i=1}^{K_n-1} \left( \frac{1}{y + ix} - \frac{1}{y + i} \right) - \sum_{i=1}^{n-1} \frac{1}{y + i} = \sum_{i=1}^{K_n-1} \frac{(1-x)i}{(y + ix)(y + i)} - \sum_{i=K_n}^{n-1} \frac{1}{y + i} \quad \text{(S1.10)}
\]
\[
\leq \frac{K_n^2(1-x)}{(y + x)(y + 1)} - \frac{1}{y + K_n} = \frac{K_n^2(1-x)(y + K_n) - y^2 - (1+x)y - x}{(y + x)(y + 1)(y + K_n)} < 0,
\]
for sufficiently large $y$. Therefore, the intermediate value theorem implies that there exists a root in $(-x, \infty)$.

Next, we prove the uniqueness. Note
\[
\hat{\Phi}'_{n,x}(y) = -\sum_{i=1}^{K_n-1} \frac{i(1-x)(y + ix + y + i)}{(y + ix)^2(y + i)^2} + \sum_{i=K_n}^{n-1} \frac{1}{(y + i)^2} = -\sum_{i=1}^{K_n-1} \frac{(1-x)(y + ix + y + i)}{(y + ix)^2(y + i)^2} - \sum_{i=1}^{K_n-1} \frac{1}{(y + i)^2} + \sum_{i=K_n}^{n-1} \frac{1}{(y + i)^2}
\]
\[
= -2 \sum_{i=1}^{K_n-1} \frac{(1-x)i}{(y + ix)(y + i)^2} + \sum_{i=K_n}^{n-1} \frac{1}{(y + i)^2} \leq -\frac{2}{y + K_n - 1} \sum_{i=1}^{K_n-1} \frac{(1-x)i}{(y + ix)(y + i)^2} + \sum_{i=K_n}^{n-1} \frac{1}{(y + i)^2},
\]
and hence, if $\hat{\Phi}'_{n,x}(y) \geq 0$, then $Q_n \leq ((y + K_n - 1)/2) \cdot \sum_{i=K_n}^{n-1} (y + i)^{-2}$. This and (S1.10) result in
\[
\hat{\Phi}_{n,x}(y) = Q_n - \sum_{i=K_n}^{n-1} \frac{1}{y + i} \leq \frac{y + K_n - 1}{2} \sum_{i=K_n}^{n-1} \frac{1}{(y + i)^2} - \sum_{i=K_n}^{n-1} \frac{1}{y + i} = \sum_{i=K_n}^{n-1} \frac{y + K_n - 1 - 2(y + i)}{2(y + i)^2}
\]
\[
= \sum_{i=K_n}^{n-1} \frac{K_n - 2i - y}{2(y + i)^2} < \sum_{i=K_n}^{n-1} \frac{K_n - 2i}{2(y + i)^2} < -\frac{K_n}{2(y + K_n)^2} < 0,
\]
where we used $y > -x > -1$ for the second inequality. Therefore, it holds that
\[
\hat{\Phi}'_{n,x}(y) \geq 0 \Rightarrow \hat{\Phi}_{n,x}(y) < 0, \quad \text{(S1.11)}
\]
which implies the uniqueness of the solution of $\hat{\Phi}_{n,x}(y) = 0$ on $(-x, \infty)$. Let $\hat{y}_n(x)$ be the unique solution. Then, $\hat{\Phi}_{n,x}(\hat{y}_n(x)) < 0$ is obvious from (S1.11) and $\hat{\Phi}_{n,x}(\hat{y}_n(x)) = 0$.

**S1.9 Derivation of (3.26)**

Section S1.8 implies that $\hat{y}_n(x)$ is the unique root of $\hat{\Phi}_{n,x}$ on $(-x, \infty)$, which is defined by (S1.9), and hence, $\hat{y}_n(x)$ satisfies the following equality:
\[
\forall x \in (0, 1), \quad \sum_{i=1}^{K_n-1} \frac{1}{\hat{y}_n(x) + ix} = \sum_{i=1}^{n-1} \frac{1}{\hat{y}_n(x) + i} \quad \text{and} \quad \hat{y}_n(x) > -x. \quad \text{(S1.12)}
\]
Then, we have

\[
\hat{\Psi}_n(x) = \Psi_n(x, \hat{y}_n(x)) = \frac{1}{K_n} \sum_{i=1}^{K_n-1} \frac{i}{\hat{y}_n(x) + ix} - \sum_{j=2}^{n} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i - x}
\]

\[
= \frac{K_n - 1}{K_n x} - \frac{1}{K_n x} \sum_{i=1}^{n-1} \frac{\hat{y}_n(x)}{\hat{y}_n(x) + i} - \sum_{j=2}^{n} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i - x},
\]

\[
= \frac{K_n - 1}{K_n x} - \frac{1}{K_n x} \sum_{i=1}^{n-1} \frac{\hat{y}_n(x)}{\hat{y}_n(x) + i} - \sum_{j=2}^{n} \frac{S_{n,j}}{K_n} \sum_{i=1}^{j-1} \frac{1}{i - x},
\]

where we used (S1.12) for the fourth equality and apply \(\hat{z}_n(x) = \hat{y}_n(x)/x\) to the last equality.

**S1.10 Proof of Lemma 3.20**

**Proof of (A)**

Suppose \(1 < K_n < n\). Then, for all \(x \in (0, 1)\), Section S1.8 implies that \(\hat{y}_n(x)\) is the unique solution of

\[
\Phi_n(x, y) = \sum_{i=1}^{K_n-1} \frac{1}{y + ix} - \sum_{i=1}^{n-1} \frac{1}{y + i} = 0
\]

and \(\partial_y \Phi_n(x, \hat{y}_n(x)) < 0\). Therefore, implicit function theorem implies

\[
\hat{y}_n'(x) = -\partial_x \Phi_n(x, y)/\partial_y \Phi_n(x, y).
\]

Then, the derivative of \(\hat{z}_n(x) = \hat{y}_n(x)/x\) can be written as

\[
\hat{z}_n'(x) = \frac{-\hat{y}_n(x) + x\hat{y}_n'(x)}{x^2} = \frac{-\hat{y}_n(x)\partial_x \Phi_n(x, \hat{y}_n(x)) - x\partial_x \Phi_n(x, \hat{y}_n(x))}{x^2\partial_y \Phi_n(x, \hat{y}_n(x))}. \quad (S1.13)
\]

Note that the numerator of (S1.13) is calculated as

\[
-\hat{y}_n(x)\partial_x \Phi_n(x, \hat{y}_n(x)) - x\partial_x \Phi_n(x, \hat{y}_n(x))
\]

\[
= \sum_{i=1}^{K_n-1} \frac{\hat{y}_n(x)}{\hat{y}_n(x) + i} - \sum_{i=1}^{n-1} \frac{\hat{y}_n(x) + i}{\hat{y}_n(x) + i} + \sum_{i=1}^{K_n-1} \frac{ix}{\hat{y}_n(x) + i}^2 + \sum_{i=1}^{n-1} \frac{1}{\hat{y}_n(x) + i}^2 = \sum_{i=1}^{K_n-1} \frac{1}{\hat{y}_n(x) + i}^2 - \sum_{i=1}^{n-1} \frac{\hat{y}_n(x) + i}{\hat{y}_n(x) + i}^2 - \sum_{i=1}^{n-1} \frac{1}{\hat{y}_n(x) + i}^2
\]

\[
= \sum_{i=1}^{n-1} \frac{1}{\hat{y}_n(x) + i} - \sum_{i=1}^{n-1} \frac{\hat{y}_n(x) + i}{\hat{y}_n(x) + i}^2 = \sum_{i=1}^{n-1} \frac{i}{\hat{y}_n(x) + i}^2 = \sum_{i=1}^{n-1} \frac{i}{(\hat{\zeta}_n(x) + i)^2} > 0,
\]

where we use (S1.12) for the third equality. In contrast, the denominator of (S1.13) is negative owing to \(\partial_y \Phi_n(x, \hat{y}_n(x)) < 0\), written as

\[
0 > x^2\partial_y \Phi_n(x, \hat{y}_n(x)) = -\sum_{i=1}^{K_n-1} \frac{x^2}{(\hat{y}_n(x) + i)^2} + \sum_{i=1}^{n-1} \frac{x^2}{(\hat{y}_n(x) + i)^2}
\]

\[
= -\sum_{i=1}^{K_n-1} \frac{1}{(\hat{\zeta}_n(x) + i)^2} + \sum_{i=1}^{n-1} \frac{x^2}{(\hat{\zeta}_n(x) + i)^2}.
\]
Therefore, we have
\[0 > \hat{z}'_n(x) = \frac{\sum_{i=1}^{n-1} i/(x\hat{z}_n(x) + i)^2}{\sum_{i=1}^{n-1} (\hat{z}_n(x) + i)^{-2} + \sum_{i=1}^{n-1} x^2/(x\hat{z}_n(x) + i)^2},\]
thereby completing the proof of (A).

Toward the proof of (B) and (C), we derive the following non-asymptotic inequality.

**Lemma S1.1.** Suppose \(1 < K_n < n\). Then, for all \(x \in (0, 1)\), it holds that
\[|\hat{z}_n(x)| \leq 1 \lor (A_n(x) \land B_n(x) \land C_n(x; \alpha)),\]
where \(A_n(x), B_n(x)\) and \(C_n(x; \alpha)\) are defined by
\[A_n(x) := \frac{nK_n}{x(n - K_n)}, \quad B_n(x) := K_n \left\{ \left( \frac{n + \hat{z}_n(x)}{1 + \hat{z}_n(x)} \right)^x - 1 \right\}, \quad C_n(x; \alpha) := n^{\alpha - 1} \left( \frac{2K_n + \hat{z}_n(x)}{n^\alpha} \right)^{\frac{1 + x}{x}}.\]

**Proof.** We fix \(x \in (0, 1)\). Suppose \(\hat{z}_n(x) < 1\). Then the assertion is obvious from \(1 > \hat{z}_n(x) = \hat{g}_n(x)/x > -x/x = -1\) so that \(|\hat{z}_n(x)| < 1\).

Now we assume \(\hat{z}_n(x) \geq 1\). Note that \(x \cdot \Phi_n(x, x\hat{z}_n(x)) = x \cdot 0 = 0\) is equivalent to
\[\sum_{i=1}^{K_n-1} \frac{x}{x\hat{z}_n(x) + i} \leq \sum_{i=1}^{n-1} \frac{x}{x\hat{z}_n(x) + i} = 0 \iff \sum_{i=1}^{n-1} \frac{x}{x\hat{z}_n(x) + i} = \sum_{i=1}^{K_n-1} \frac{1}{\hat{z}_n(x) + i} = \sum_{i=1}^{K_n-1} \frac{1}{\hat{z}_n(x) + i} = S1.14\]
Then, (S1.14) implies
\[
\frac{x(n - 1)}{x\hat{z}_n(x) + n - 1} \leq \sum_{i=1}^{n-1} \frac{x}{x\hat{z}_n(x) + i} \leq \sum_{i=1}^{K_n-1} \frac{1}{\hat{z}_n(x) + i} \leq \frac{K_n - 1}{\hat{z}_n(x) + 1} \Rightarrow \frac{\hat{z}_n(x)}{K_n - 1} + \frac{1}{K_n - 1} \leq \frac{\hat{z}_n(x)}{n - 1} + \frac{1}{x} \Rightarrow \hat{z}_n(x) \leq \frac{(n - 1)(K_n - 1 - x)}{x(n - K_n)} \leq \frac{nK_n}{x(n - K_n)} = A_n(x). \tag{S1.15}\]

In contrast, elementary calculus implies
\[
\forall m \in \mathbb{N}_{\geq 2}, \forall \delta > 0, \log \left( \frac{\delta + m}{\delta + 1} \right) < \sum_{i=1}^{m-1} \frac{1}{\delta + i} < \log \left( \frac{\delta + m - 1}{\delta} \right) < \log \left( \frac{\delta + m}{\delta} \right).\]

Then, this and the assumption \(\hat{z}_n(x) \geq 1 > 0\) result in
\[
x \log \left( \frac{\hat{z}_n(x) + n}{\hat{z}_n(x) + 1} \right) \leq \sum_{i=1}^{n-1} \frac{x}{\hat{z}_n(x) + i} \leq \sum_{i=1}^{n-1} \frac{x}{x\hat{z}_n(x) + i} = \sum_{i=1}^{K_n-1} \frac{1}{\hat{z}_n(x) + i} < \log \left( \frac{\hat{z}_n(x) + K_n}{\hat{z}_n(x)} \right) \Rightarrow \left( \frac{\hat{z}_n(x) + n}{\hat{z}_n(x) + 1} \right)^x < \hat{z}_n(x) + K_n \leq \hat{z}_n(x) + \frac{K_n}{\hat{z}_n(x)} \leq K_n \left\{ \left( \frac{\hat{z}_n(x) + n}{\hat{z}_n(x) + 1} \right)^x - 1 \right\}^{-1} = B_n(x). \tag{S1.17}\]

Furthermore, (S1.16) and the assumption \(\hat{z}_n(x) \geq 1 > 0\) yield
\[
\frac{\hat{z}_n(x)}{(\hat{z}_n(x) + 1)^x} < \frac{\hat{z}_n(x) + K_n}{(\hat{z}_n(x) + n)^x} \leq \frac{\hat{z}_n(x) + K_n}{n^x} \leq \frac{(1 + \hat{z}_n(x))^x \hat{z}_n(x) + K_n}{n^x} \leq \frac{(1 + 1)^x \hat{z}_n(x) + K_n}{n^x} < n^{\alpha - x}. \frac{2}{\hat{z}_n(x) + K_n} \Rightarrow \frac{\hat{z}_n(x)}{n^{\alpha - x}} \left( \frac{2}{\hat{z}_n(x) + K_n} \right)^{\frac{1}{\alpha}} = C_n(x; \alpha). \tag{S1.18}\]
Combining (S1.15), (S1.17), and (S1.18), we get
\[ \hat{z}_n(x) \geq 1 \Rightarrow |\hat{z}_n(x)| < A_n(x) \wedge B_n(x) \wedge C_n(x; \alpha), \]
thereby completing the proof. 

**Proof of (B)**

We fix \( x \in (0, 1) \). For \( A_n(x) \) in Lemma S1.1, \( K_n = O_p(n^\alpha) = o_p(n) \) implies
\[ \frac{A_n(x)}{n} = \frac{K_n}{x(n-K_n)} = o_p(1), \]
and hence \( |\hat{z}_n(x)| \leq 1 \vee A_n(x) = o_p(n) \). Considering this, for \( B_n(x) \) in Lemma S1.1, it holds that
\[ \frac{B_n(x)}{n^\alpha} = \frac{K_n}{n^\alpha} \cdot \left\{ \left( \frac{n + \hat{z}_n(x)}{1 + \hat{z}_n(x)} \right)^\frac{\alpha}{\alpha - 1} - 1 \right\}^{-1} \rightarrow M_{\alpha \theta} \cdot 0 = 0 \text{ in probability}, \]
which implies \( |\hat{z}_n(x)| \leq 1 \vee B_n(x) = o_p(n^\alpha) \). Then, for \( C_n(x; \alpha) \) in Lemma S1.1, we get
\[ n^{-\frac{\alpha}{\alpha - 1}} \cdot C_n(x; \alpha) = \left( \frac{2K_n + \hat{z}_n(x)}{n^\alpha} \right)^{\frac{1}{\alpha - 1}} \rightarrow (2M_{\alpha \theta} + 0)^{\frac{1}{\alpha - 1}} = \left( 2M_{\alpha \theta} \right)^{\frac{1}{\alpha - 1}} \text{ in probability}, \]
where we used \( K_n/n^\alpha \rightarrow M_{\alpha \theta} \) (a.s.). Therefore,
\[ |\hat{z}_n(x)| \leq 1 \vee C_n(x; \alpha) = 1 \vee O_p(n^{\frac{\alpha}{\alpha - 1}}) = \begin{cases} O_p(n^{\frac{\alpha}{\alpha - 1}}) & 0 < x < \alpha \\ O_p(1) & \alpha \leq x < 1 \end{cases}, \]
thereby completing the proof.

**Proof of (C)**

1. **Step 1.** \( \sup_{x \in [\alpha \pm \delta_n]} |\hat{z}_n(x)| = O_p(1) \)

Note that we can take \((s, t)\) satisfying \( 0 < s < \alpha < t < 1 \) and \([\alpha \pm \delta_n] \subset [s, t] \subset (0, 1)\) for sufficiently large \( n \) by \( \delta_n = o(1/\log n) = o(1) \). Considering \( \hat{z}_n(x) \) is monotone on \((0, 1)\) by (A), (B) implies
\[ \sup_{x \in [\alpha \pm \delta_n]} |\hat{z}_n(x)| \leq \sup_{x \in [s, t]} |\hat{z}_n(x)| \leq |\hat{z}_n(s)| + |\hat{z}_n(t)| = O_p(n^{\frac{\alpha}{\alpha - 1}}) + O_p(1) = o_p(n^\alpha). \]

Then, for \( C_n(x; \alpha) \) in Lemma S1.1, it holds that
\[ \log C_n(x = \alpha \pm \delta_n; \alpha) = \frac{2K_n + \hat{z}_n(\alpha \pm \delta_n)}{n^\alpha} \log n + \frac{1}{1 - \alpha \mp \delta_n} \log \left( \frac{2K_n + \hat{z}_n(\alpha \pm \delta_n)}{n^\alpha} \right) \]
\[ \rightarrow 0 + \frac{1}{1 - \alpha} \log(2M_{\alpha \theta} + 0) = O_p(1), \]
and hence \( C_n(\alpha \pm \delta_n; \alpha) = O_p(1) \). Therefore, the monotonicity of \( \hat{z}_n(x) \) on \((0, 1)\) and Lemma S1.1 imply
\[ \sup_{x \in [\alpha \pm \delta_n]} |\hat{z}_n(x)| \leq |\hat{z}_n(\alpha \pm \delta_n)| \leq 1 \vee C_n(\alpha \pm \delta_n; \alpha) = O_p(1), \]
which completes the proof.

35
Step 2. \( \sup_{x \in [a \pm \delta_n]} |f_\alpha(\hat{z}_n(x)) - \log(K_n/n^\alpha)| = o_p(1) \)

Denote \( \hat{z}_n(\alpha \pm \delta_n) \) by \( \hat{z}_n^\pm \) and \( \alpha \pm \delta_n \) by \( \alpha_n^\pm \). Note that \( \hat{z}_n'(x) < 0 \) by (A) and \( f_\alpha'(z) > 0 \) by Lemma 3.2 imply \( (f_\alpha \circ \hat{z}_n)'(x) < 0 \) for all \( x \in (0, 1) \), and hence, it suffices to show

\[
f_\alpha(\hat{z}_n^\pm) - \log(K_n/n^\alpha) = o_p(1).
\]

Considering \( \alpha_n^\pm \cdot \Phi_n(\alpha_n^\pm, n^\pm \hat{z}_n^\pm) = \alpha_n^\pm \cdot 0 = 0 \), we have

\[
0 = \sum_{i=1}^{n-1} \frac{\alpha_n^\pm}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i\alpha_n^\pm} - \sum_{i=1}^{n-1} \frac{\alpha_n^\pm}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} = \sum_{i=1}^{n-1} \frac{1}{\hat{z}_n^\pm + i} - \sum_{i=1}^{n-1} \frac{\alpha_n^\pm}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} \\
= K_{n-1} \left( \frac{1}{\hat{z}_n^\pm + i} - \sum_{i=1}^{n-1} \frac{\alpha_n^\pm - \alpha}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} \right) - \alpha \sum_{i=1}^{n-1} \left( \frac{1}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} - \frac{1}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} \right) - \sum_{i=1}^{n-1} \frac{\alpha_n^\pm}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} \\
= \psi(K_n + \hat{z}_n^\pm) - \psi(1 + \hat{z}_n^\pm) - \alpha \sum_{i=1}^{n-1} \frac{\alpha_n^\pm - \alpha}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} - \alpha \sum_{i=1}^{n-1} \frac{(\alpha - \alpha_n^\pm)\hat{z}_n^\pm}{(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)} \\
- \alpha \psi(n + \alpha \hat{z}_n^\pm) + \alpha \psi(1 + \alpha \hat{z}_n^\pm),
\]

where \( \psi \) is the digamma function. Using \( f_\alpha(z) = \psi(1 + z) - \alpha \psi(1 + \alpha z) \), the above equality is equivalent to

\[
f_\alpha(\hat{z}_n^\pm) - \log(K_n/n^\alpha) = (\psi(K_n + \hat{z}_n^\pm) - \log K_n) - \alpha(\psi(n + \alpha_n^\pm \hat{z}_n^\pm) - \log n) \\
- \sum_{i=1}^{n-1} \frac{\alpha_n^\pm - \alpha}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} - \sum_{i=1}^{n-1} \frac{\alpha(\alpha - \alpha_n^\pm)\hat{z}_n^\pm}{(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)}.
\]

Note that \( \hat{z}_n^\pm = O_p(1) \) by Step 1. Then, the first and second terms are \( o_p(1) \) by Lemma 3.12 applied with \( \hat{z}_n^\pm/K_n = O_p(1)/K_n = o_p(1) \) and \( \hat{z}_n^\pm/n = O_p(1)/n = o_p(1) \). As for the third and fourth terms, \( \alpha_n^\pm \in [s, t] \subset (0, 1) \) for sufficiently large \( n \) and \( \hat{z}_n^\pm = O_p(1) \) by Step 1 result in

\[
\left| \sum_{i=1}^{n-1} \frac{\alpha_n^\pm - \alpha}{\alpha_n^\pm \cdot \hat{z}_n^\pm + i} \right| \leq \delta_n \sum_{i=1}^{n-1} \frac{1}{\alpha_n^\pm} \leq \delta_n \sum_{i=1}^{n-1} \frac{1}{i} = o(1/\log n)O_p(\log n) = o_p(1),
\]

\[
\left| \sum_{i=1}^{n-1} \frac{\alpha(\alpha - \alpha_n^\pm)\hat{z}_n^\pm}{(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)(\alpha_n^\pm \cdot \hat{z}_n^\pm + i)} \right| \leq \delta_n |\hat{z}_n^\pm| \sum_{i=1}^{n-1} \frac{1}{(-t+i)(-\alpha+i)} = o(1/\log n)O_p(1)O(1) = o_p(1).
\]

Therefore, we have \( f_\alpha(\hat{z}_n^\pm) - \log(K_n/n^\alpha) = o_p(1) \), thereby completing the proof.

S2 Additional numerical simulations

S2.1 Visualization of limit law of Maximum Likelihood Estimator for \( \theta \)

For \( \hat{\theta}_{n, \alpha} \) in Definition 3.2, the following almost sure convergence holds (Remark 3.14):

\[
\hat{\theta}_{n, \alpha} \to \alpha f_\alpha^{-1}(\log M_{\alpha \theta}) \ (a.s.),
\]

where \( M_{\alpha \theta} \sim \text{GMLf}(\alpha, \theta) \) and \( f_\alpha^{-1} \) is the inverse of \( f_\alpha \) defined by (3.2). Herein, we confirm that the limit law is distributed around \( \theta \) by numerical simulations. For various pairs of \( (\alpha, \theta) \), we plot the histogram of \( \hat{\theta}_{n, \alpha} \) in Figure 8 with a sample size fixed to 1000 and \( n = 2^{16} \). We see that it is distributed around \( \theta \). Theoretical analysis of the law \( \alpha f_\alpha^{-1}(\log M_{\alpha \theta}) \) is one of our future research topics.
Figure 8: Histogram of $\hat{\theta}_{n,\alpha}$ with sample size 1000 and $n = 2^{16}$. The bold bins include the true value of $\theta$.
