Summary

Regression modeling is the workhorse of statistics and there is a vast literature on estimation of the regression function. It is realized in recent years that in regression analysis the ultimate aim may be the estimation of a level set of the regression function, instead of the estimation of the regression function itself. The published work on estimation of the level set has thus far focused mainly on nonparametric regression, especially on point estimation. In this paper, the construction of confidence sets for the level set of linear regression is considered. In particular, exact $1 - \alpha$ level upper, lower and two-sided confidence sets are constructed for the normal-error linear regression. It is shown that these confidence sets are closely connected with the corresponding $1 - \alpha$ level simultaneous confidence bands. It is also pointed out that the construction method is readily applicable to other parametric regression models where the mean re-
response depends on a linear predictor through a monotonic link function, which include generalized linear models, linear mixed models and generalized linear mixed models. Therefore the method proposed in this paper is widely applicable. Two examples are given to illustrate the method.

**keywords** Confidence sets; linear regression; nonparametric regression; parametric regression; simultaneous confidence bands; statistical inference.
1 INTRODUCTION

Let \( Y = h(x) + e \) where \( Y \in \mathbb{R}^1 \) is the response, \( x \in \mathbb{R}^p \) is the covariate (vector), \( h \) is the regression function, and \( e \) is the random error. In regression analysis, there is a vast literature on how to estimate the regression function \( h \), based on the observed data \((Y_i, x_i), i = 1, \ldots, n\).

In recent years, it is realized that an important problem in regression is the inference of the \( \lambda \)-level set

\[
G = G_h(\lambda) = \{ x \in K : h(x) \geq \lambda \}
\]

where \( \lambda \) is a given number, and \( K \subset \mathbb{R}^p \) is a given covariate \( x \) region of interest. It is argued forcefully in Scott and Davenport (2007) that “In a wide range of regression problems, if it is worthwhile to estimate the regression function \( h \), it is also worthwhile to estimate certain level sets. Moreover, these level sets may be of ultimate importance. And in many classification problems, labels are obtained by thresholding a continuous variable. Thus, estimating regression level sets may be a more appropriate framework for addressing many problems that are currently envisioned in other ways”. For example, when considering a regression model of infant systolic blood pressure on birth weight and age, it is of interest to identify the covariate region over which the systolic blood pressure exceeds (or falls below) a certain \( \lambda \). For a regression model of perinatal mortality rate on birth weigh, it is interesting to identify the range of birth weight over which the perinatal mortality rate exceeds a certain \( \lambda \).

See more details on these two examples in Section 3. Other possible applications have been pointed out, for example, in Scott and Davenport (2007) and Dau et al. (2020). Inference of the level set \( G \) is an important component of the more general field of subgroup analysis (cf. Wang et al., 2007, Herrera et al., 2011, Ting et al., 2020).
In nonparametric regression where $h$ is not assumed to have a specific form, point estimation of $G$ aims to construct $\hat{G}$ to approximate $G$ using the observed data. This has been considered by Cavalier (1997), Polonik and Wang (2005), Willett and Nowak (2007), Scott and Davenport (2007), Dau et al. (2020) and Reeve et al. (2021) among others. The main focus of these works is on large sample properties such as consistency and rate of convergence. Related work on estimation of level-sets of a nonparametric density function can be found in Hartigan (1987), Tsybakov (1997), Cadre (2006), Mason and Polonik (2009) and Chen et al. (2017). Confidence-set estimation of $G$ aims to construct sets $\hat{G}$ to contain or be contained in $G$ with a pre-specified confidence level $1-\alpha$. Large sample approximate $1-\alpha$ confidence-set estimation of $G$ is considered in Mammen and Polonik (2013).

In this paper confidence-set estimation of $G$ for linear regression is considered. It is shown that the problem is closely related to simultaneous confidence bands for a linear regression function, which have been considered in Wynn and Bloomfield (1971), Naiman (1984, 1986), Piegorsch (1985a,b), Sun and Loader (1994), Liu and Hayter (2007) and numerous others; see Liu (2010) for an overview. Lower, upper and two-sided confidence-set estimators of $G$ of exactly $1-\alpha$ level are provided in this paper. It is also pointed out that the method can be directly extended to, for example, the generalized linear regression models, though the confidence-set estimations are of asymptotic $1-\alpha$ level since the simultaneous confidence bands are of asymptotic $1-\alpha$ level in this case. A related problem is the confidence-set estimation of the maximum (or minimum) point of a linear regression model; see Wan et al. (2015, 2016) and the references therein.

The layout of the paper is as follows. The construction method of confidence-set estimators
is given in Section 2. The method is illustrated with two examples in Section 3. Section 4 contains conclusions and a brief discussion. Finally the appendix sketches the proof of a theorem.

# 2 Method

The confidence sets for $G$ are constructed in this section. Let the normal-error linear regression model be given by

$$Y = h(x) + e = \beta_0 + \beta_1 x_1 + \cdots + \beta_p x_p + e,$$

where the independent errors $e \sim N(0, \sigma^2)$. From the observed sample of observations $(Y_i, x_i), i = 1, \cdots, n$, the usual estimator of $\beta = (\beta_0, \cdots, \beta_p)^T$ is given by $\hat{\beta} = (X^T X)^{-1} X^T Y$

where $X$ is the $n \times (p + 1)$ design matrix and $Y = (Y_1, \cdots, Y_n)^T$. The estimator of the error variance $\sigma^2$ is given by $\hat{\sigma}^2$. It is known that $\hat{\beta} \sim N(\beta, \sigma^2(X^T X)^{-1}), \hat{\sigma}^2 \sim \sigma^2 \chi^2_\nu/\nu$ with $\nu = n - p - 1$, and $\hat{\beta}$ and $\hat{\sigma}^2$ are independent.

Let $\tilde{x} = (1, x^T)^T = (1, x_1, \cdots, x_p)^T$. Suppose the upper, lower and two-sided $1 - \alpha$ simultaneous confidence bands over the covariate region $x \in K$ are given, respectively, by

$$P \left\{ \tilde{x}^T \beta \leq \tilde{x}^T \hat{\beta} + c_1 \hat{\sigma} m(x) \forall x \in K \right\} = 1 - \alpha \quad (1)$$

$$P \left\{ \tilde{x}^T \beta \geq \tilde{x}^T \hat{\beta} - c_1 \hat{\sigma} m(x) \forall x \in K \right\} = 1 - \alpha \quad (2)$$

$$P \left\{ \tilde{x}^T \beta - c_2 \hat{\sigma} m(x) \leq \tilde{x}^T \beta \leq \tilde{x}^T \hat{\beta} + c_2 \hat{\sigma} m(x) \forall x \in K \right\} = 1 - \alpha \quad (3)$$
where \( m(x) > 0 \) is a given function of \( x \), and \( c_1 > 0 \) and \( c_2 > 0 \) are the critical constants to achieve the exact \( 1 - \alpha \) confidence level; see Section 3 below for the choice of \( m(x) \) and the computation of \( c_1 \) and \( c_2 \). It is worth emphasizing that the three probabilities in (1-3) do not depend on the unknown parameters \( \beta \in \mathbb{R}^{p+1} \) and \( \sigma > 0 \), and that \( c_1 < c_2 \).

From the simultaneous confidence bands in (1-3), define the confidence sets as

\[
\hat{G}_{1u} = \left\{ x \in K : \hat{\beta}^T \hat{x} + c_1 \hat{\sigma} m(x) \geq \lambda \right\},
\]

\[
\hat{G}_{1l} = \left\{ x \in K : \hat{\beta}^T \hat{x} - c_1 \hat{\sigma} m(x) \geq \lambda \right\},
\]

\[
\hat{G}_{2u} = \left\{ x \in K : \hat{\beta}^T \hat{x} + c_2 \hat{\sigma} m(x) \geq \lambda \right\}, \quad \hat{G}_{2l} = \left\{ x \in K : \hat{\beta}^T \hat{x} - c_2 \hat{\sigma} m(x) \geq \lambda \right\}.
\]

The following theorem establishes that \( \hat{G}_{1u} \) is an upper, \( \hat{G}_{1l} \) is a lower, and \( [\hat{G}_{2l}, \hat{G}_{2u}] \) is a two-sided, confidence set for \( G \) of exactly \( 1 - \alpha \) level. A proof is sketched in the appendix.

**Theorem.** We have

\[
\inf_{\beta \in \mathbb{R}^{p+1}, \sigma > 0} \mathbb{P}\left\{ G \subseteq \hat{G}_{1u} \right\} = 1 - \alpha, \quad (7)
\]

\[
\inf_{\beta \in \mathbb{R}^{p+1}, \sigma > 0} \mathbb{P}\left\{ \hat{G}_{1l} \subseteq G \right\} = 1 - \alpha, \quad (8)
\]

\[
\inf_{\beta \in \mathbb{R}^{p+1}, \sigma > 0} \mathbb{P}\left\{ \hat{G}_{2l} \subseteq G \subseteq \hat{G}_{2u} \right\} = 1 - \alpha. \quad (9)
\]

From the definitions in (4-6), it is clear that each set \( \hat{G} \) is given by all the points in \( K \) at which the corresponding simultaneous confidence band is at least as high as the given threshold \( \lambda \). Note that each set could be an empty set when \( \lambda \) is sufficiently large, and become \( K \) when \( \lambda \) is sufficiently small. Of course, each set cannot be larger than the given covariate.
set \( K \) from the definition. Since \( c_1 > 0 \) and \( c_2 > 0 \), it is clear that \( \hat{G}_{1l} \subseteq \hat{G}_{1u} \) and \( \hat{G}_{2l} \subseteq \hat{G}_{2u} \). Since \( c_1 < c_2 \), it is clear that \( \hat{G}_{1u} \subseteq \hat{G}_{2u} \) and \( \hat{G}_{2l} \subseteq \hat{G}_{1l} \). Hence \( \hat{G}_{2l} \subseteq \hat{G}_{1l} \subseteq \hat{G}_{1u} \subseteq \hat{G}_{2u} \).

Intuitively, since the regression function \( \tilde{x}^T \beta \) is bounded from above by the upper simultaneous confidence band \( \tilde{x}^T \hat{\beta} + c_1 \hat{\sigma}_m(x) \) over the region \( x \in K \), the level set \( G \) cannot be bigger than the set \( \hat{G}_{1u} \). Similarly, since the regression function \( \tilde{x}^T \beta \) is bounded from below by the lower simultaneous confidence band \( \tilde{x}^T \hat{\beta} - c_1 \hat{\sigma}_m(x) \) over the region \( x \in K \), the level set \( G \) cannot be smaller than the set \( \hat{G}_{1l} \). Finally, since the regression function \( \tilde{x}^T \beta \) is bounded, simultaneously, from below by the lower confidence band \( \tilde{x}^T \hat{\beta} - c_2 \hat{\sigma}_m(x) \), and from above by the upper confidence band \( \tilde{x}^T \hat{\beta} + c_2 \hat{\sigma}_m(x) \), over the region \( x \in K \), the level set \( G \) must contain the set \( \hat{G}_{2l} \) and be contained in the set \( \hat{G}_{2u} \) simultaneously. The theorem above asserts that each of the upper, lower and two-sided confidence sets is of confidence level \( 1 - \alpha \) exactly.

Instead of the level set \( G \), the set

\[
M = M_h(\lambda) = \{ x \in K : h(x) \leq \lambda \}
\]

may be of interest in some applications; see e.g. Example 2 in Section 3. In this case, one can consider the regression of \(-Y\) on \( x \), given by \(-Y = -h(x) + (-e)\), and hence \( M \) becomes the level set \( G \) of the regression function \(-h(x)\) with level \(-\lambda\).

The confidence sets given in (4-6) for the normal-error linear regression can be generalized to other models that involve a linear predictor \( \tilde{x}^T \beta \). In generalized linear models, linear mixed models and generalized linear mixed models (cf. McCulloch and Searle, 2001 and Faraway,
2016), for example, the mean response $E(Y)$ is often related to a linear predictor $\tilde{x}^T \beta$ by a given monotonic link function $L(\cdot)$, that is, $L[E(Y)] = \tilde{x}^T \beta$. Since $L(\cdot)$ is monotone, the set of interest $\{ x \in K : E(Y) \geq L_0 \}$, for a given threshold $L_0$, becomes either $\{ x \in K : \tilde{x}^T \beta \geq \lambda \}$ or $\{ x \in K : \tilde{x}^T \beta \leq \lambda \}$, where $\lambda = L(L_0)$, depending on whether the function $L(\cdot)$ is increasing or decreasing. However, when the distribution of $\hat{\beta}$ is asymptotically normal $N(\beta, \hat{\Sigma})$, the simultaneous confidence bands of the forms in (1-3) are of approximate $1 - \alpha$ level; see, e.g., Liu (2010, Chapter 8). As a result, the corresponding confidence sets of the forms in (4-6) are of approximate $1 - \alpha$ level too.

3 Examples

In this section, two examples are used to illustrate the confidence sets given in (4-6). The R code for all the computation in this section is available from the authors.

Example 1. In Example 1.1 of Liu (2010), a linear regression model of systolic blood pressure ($Y$) on the two covariates birth weight in oz ($x_1$) and age in days ($x_2$) of an infant is considered

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + e.$$ 

Based on the measurements on $n = 17$ infants in Liu (2010, Table 1.1), the linear regression model provides a good fit with $R^2 = 95\%$. The observed values of $x_1$ range from 92 to 149, and the observed values of $x_2$ range from 2 to 5; hence we set $K = \{ x = (x_1, x_2)^T : 92 \leq x_1 \leq 149, 2 \leq x_2 \leq 5 \}$. It is of interest to identify infants, in terms of $x = (x_1, x_2)^T \in K$, that have mean systolic blood pressure larger than 97, assuming systolic blood pressure larger than 97 is
deemed to be too high. Therefore the level set \( G = G(97) = \{ x \in K : \beta_0 + \beta_1 x_1 + \beta_2 x_2 \geq 97 \} \) is of interest.

From Section 2, simultaneous confidence bands in (1-3) need to be constructed first in order to construct the confidence sets for \( G \) in (4-6). The two most popular forms of \( m(x) \) are

\[
m(x) = \sqrt{x^T (X^T X)^{-1} x} \quad \text{and} \quad m(x) = 1,
\]

corresponding to the hyperbolic and constant-width confidence bands, respectively. As the hyperbolic band is often better than the constant-width band under various optimality criteria (see, e.g., Liu and Hayter (2007) and the references therein), hyperbolic confidence bands are used in both examples in this section.

Now the critical constants \( c_1 \) and \( c_2 \) can be computed by using the method of Liu et al. (2005); see also Liu (2010, Section 3.2). In this example, with \( p = 2, n = 17, 1 - \alpha = 95\% \) and the given design matrix \( X \), \( c_2 \) is computed to be 3.11 and \( c_1 \) is computed to be 2.77.

Figure 1(a) plots the 1-sided upper confidence set \( \hat{G}_{1u} \) in the \( x \)-plane, with the region \( K \) given by the rectangle in solid line. Note that the curvilinear-boundary of \( \hat{G}_{1u} \) is given by the projection, to the \( x \)-plane, of the intersection between the horizontal plane at height \( \lambda = 97 \) and the 1-sided upper simultaneous confidence band over the region \( x \in K \). The upper confidence set \( \hat{G}_{1u} \) tells us that, with 95% confidence level, only those infants having \( x \in \hat{G}_{1u} \) may have mean systolic blood pressure larger than or equal to 97. Hence \( x \in \hat{G}_{1u} \) could be used as a screening criterion for further medical check due to concerns over too high systolic blood pressure.

Similarly, Figure 1(b) plots the 1-sided lower confidence set \( \hat{G}_{1l} \) in the \( x \)-plane. Note that the curvilinear-boundary of \( \hat{G}_{1l} \) is given by the projection, to the \( x \)-plane, of the intersection between the horizontal plane at height \( \lambda = 97 \) and the 1-sided lower simultaneous confidence
Figure 1: The 95\% confidence sets in Example 1, given by the shaded regions.
band over the region $K$. The lower confidence set $\hat{G}_{1l}$ tells us that, with 95% confidence level, infants having $x \in \hat{G}_{1u}$ do have mean systolic blood pressure larger than or equal to 97. Hence these infants should have further medical check due to concerns over excessive high systolic blood pressure.

Figure 1(c) plots the two-sided confidence set $[\hat{G}_{2l}, \hat{G}_{2u}]$ in the $x$-plane. Note that the curvilinear-boundaries of $[\hat{G}_{2l}, \hat{G}_{2u}]$ are given by the projection, to the $x$-plane, of the intersection between the horizontal plane at height $\lambda = 97$ and the two-sided confidence band over the region $K$. The two-sided confidence set tells us that, with 95% confidence level, infants having $x \in K \setminus \hat{G}_{2u}$ are not of concern, infants having $x \in \hat{G}_{2l}$ are of concern, and infants having $x \in \hat{G}_{2u}$ are possibly of concern, in terms of excessive high mean systolic blood pressure.

Figure 1(d) plots $\hat{G}_{1u}$, $\hat{G}_{1l}$ and $[\hat{G}_{2l}, \hat{G}_{2u}]$ in the same picture for the purpose of comparison. It is clear from the figure that $\hat{G}_{2l} \subseteq \hat{G}_{1l} \subseteq \hat{G}_{1u} \subseteq \hat{G}_{2u}$ as pointed out in Section 2.

Note that when $\lambda$ is large, 100 say, the horizontal plane at height $\lambda$ and the 1-sided lower simultaneous confidence band do not intersect over the region $K$. In this case the 1-sided lower confidence set $\hat{G}_{1l}$ is an empty set. Similar observations hold for other confidence sets.

**Example 2.** Selvin (1998, p224) provided a data set on perinatal mortality (fetal deaths plus deaths within the first month of life) rate (PMR) and birth weight (BW) collected in California in 1998. The interest is on modelling how PMR changes with BW; Selvin (1998) considered fitting a 4th order polynomial regression model between $Y = \log(-\log(\text{PMR}))$ and $x = \text{BW}$:

$$Y = \beta_0 + \beta_1 x + \beta_2 x^2 + \beta_3 x^3 + \beta_4 x^4 + e.$$
Here we will focus on the black infants only, using the 35 observations extracted from Selvin (1998) and given in Liu (2010, Table 7.1). The 4th order polynomial regression model provides a good fit with $R^2 = 97\%$.

The observed values of $x$ range from 0.85 to 4.25 and so we set $K = [0.85, 4.25]$. We are interested in the values of $x \in K$ that may result in excessive high PMR. Since $Y = \log(-\log(PMR))$ and $\log(-\log(\cdot))$ is monotone decreasing, we are interested in the set $M = \{x \in K : \beta_0 + \beta_1 x + \cdots + \beta_4 x^4 \leq \lambda\}$ in (10), with $\lambda = \log(-\log(0.01)) = 1.527$ assuming that $PMR \geq 0.01$ is regarded as excessively high.

From Section 2, simultaneous confidence bands for $-\beta_0 - \beta_1 x - \cdots - \beta_4 x^4$ of the forms in (1-3) over $x \in K$ need to be constructed first in order to construct the confidence sets for $M$ in (10), which is the same as $G = \{x \in K : -\beta_0 - \beta_1 x - \cdots - \beta_4 x^4 \geq -\lambda\}$. The critical constants $c_1$ and $c_2$ of the hyperbolic confidence bands, which have $m(x) = \sqrt{\tilde{x}^T (X^T X)^{-1} \tilde{x}}$ with $\tilde{x} = (1, x, \cdots, x^4)^T$ in this example, can be computed by using the method of Liu et al. (2008); see also Liu (2010, Section 7.1). With $p = 4$, $n = 35$, $1 - \alpha = 95\%$ and the given design matrix $X$, $c_2$ is computed to be 2.99 and $c_1$ is computed to be 2.69.

Figure 2(a) plots the 1-sided upper simultaneous confidence band $-\tilde{x}^T \hat{\beta} + c_1 \hat{\sigma} m(x)$ over $x \in K$, and the 1-sided upper confidence set $\hat{G}_{1u} = [0.85, 2.82]$ on the $x$-axis. Note that the boundary of $\hat{G}_{1u}$, 2.82, is given by the projection, to the $x$-axis, of the intersection between the horizontal line at height $-\lambda = -1.527$ and the upper simultaneous confidence band over the interval $x \in K$. The upper confidence set $\hat{G}_{1u}$ tells us that, with confidence level 95\%, only those infants having $x \in \hat{G}_{1u}$ may have $E\{\log(-\log(PMR))\} \leq 1.527$ and hence may need extra medical care due to concerns over excessive high PMR.
Figure 2: The 95% confidence sets in Example 2, indicated by the red line segments.
Similarly, Figure 2(b) plots the 1-sided lower simultaneous confidence band $-\hat{x}^T\hat{\beta} - c_1\hat{\sigma}(x)$ over $x \in K$, and the 1-sided lower confidence set $\hat{G}_{1l} = [0.85, 2.44]$ on the $x$-axis. Note that the boundary of $\hat{G}_{1l}$, 2.44, is given by the projection, to the $x$-axis, of the intersection between the horizontal line at height $-\lambda = -1.527$ and the lower simultaneous confidence band over the interval $K$. The lower confidence set $\hat{G}_{1l}$ tells us that, with confidence level 95%, infants having $x \in \hat{G}_{1u}$ do have $E\{\log(-\log(\text{PMR}))\} \leq 1.527$ and so should have extra medical care due to concerns over excessive high PMR.

Figure 2(c) plots the 2-sided simultaneous confidence band $[-\hat{x}^T\hat{\beta} - c_2\hat{\sigma}(x), -\hat{x}^T\hat{\beta} + c_2\hat{\sigma}(x)]$ over $x \in K$, and the 2-sided confidence set $[\hat{G}_{2l}, \hat{G}_{2u}] = [[0.85, 2.42], [0.85, 2.84]]$ on the $x$-axis. Note that the boundaries of $[\hat{G}_{2l}, \hat{G}_{2u}]$, 2.42 and 2.84, are given by the projection, to the $x$-axis, of the intersection between the horizontal line at height $-\lambda = -1.527$ and the two-sided confidence band over the interval $K$. The two-sided confidence set tells us that, with confidence level 95%, infants having $x \in K \setminus \hat{G}_{2u}$ are not of concern, infants having $x \in \hat{G}_{2l}$ are of concern, and infants having $x \in \hat{G}_{2u}$ are possibly of concern, in terms of excessive high PMR.

Figure 2(d) plots $\hat{G}_{1u}$, $\hat{G}_{1l}$ and $[\hat{G}_{2l}, \hat{G}_{2u}]$ in the same picture for the purpose of comparison. From this figure, it is clear again that $\hat{G}_{2l} \subseteq \hat{G}_{1l} \subseteq \hat{G}_{1u} \subseteq \hat{G}_{2u}$ as pointed out in Section 2.

4 CONCLUSION AND DISCUSSION

In this paper, the construction of confidence sets for the level set of linear regression is discussed. Exact $1 - \alpha$ level upper, lower and two-sided confidence sets are constructed for
the normal-error linear regression. It is shown that these confidence sets are constructed from the corresponding $1 - \alpha$ level simultaneous confidence bands. Hence these confidence sets and simultaneous confidence bands are closely related.

It is also pointed out in Section 2 that the construction method is readily applicable to other parametric regression models where the mean response depends on a linear predictor through a monotonic link function. Examples are generalized linear models, linear mixed models and generalized linear mixed models. Therefore the method proposed in this paper is widely applicable.

It is interesting to explore whether the construction method for linear regression in this paper, that is, using simultaneous confidence bands to construct confidence sets, could be extended to nonparametric regression. While beyond the scope of this paper, it warrants further research.

5 Appendix

In this appendix a proof of the Theorem in Section 2 is sketched.
For proving the statement in (8), we have

\[
\begin{align*}
\{ G \subseteq \hat{G}_{1u} \} \\
= \{ \forall x \in G : x \in \hat{G}_{1u} \} \\
= \{ \forall x \in G : \hat{x}^T \hat{\beta} + c_1 \hat{\sigma} m(x) \geq \lambda \} \\
= \{ \forall x \in G : \hat{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma} m(x) \geq \lambda - \hat{x}^T \beta \} \\
\supseteq \{ \forall x \in K : \hat{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma} m(x) \geq 0 \}
\end{align*}
\]

where the second equation follows directly from the definition of \( \hat{G}_{1u} \), and the “\( \supseteq \)” follows directly from the definition of \( G \). It follows therefore

\[
P \left\{ G \subseteq \hat{G}_{1u} \right\} \geq P \left\{ \forall x \in K : \hat{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma} m(x) \geq 0 \right\} = 1 - \alpha \quad (11)
\]

where the last equality is directly due to the fact that \( \hat{x}^T \hat{\beta} + c_1 \hat{\sigma} m(x) \) is an upper simultaneous confidence band for \( \hat{x}^T \beta \) over \( x \in K \) of exact \( 1 - \alpha \) level, as given in (1).

Next we show that the minimum probability over \( \beta \in \mathbb{R}^{p+1} \) and \( \sigma > 0 \) in statement (8) is
$1 - \alpha$, attained at $\beta = (\lambda, 0, \ldots, 0)^T$. At $\beta = (\lambda, 0, \ldots, 0)^T$, we have $G = K$ and so

$$\{ G \subseteq \hat{G}_{1u} \} = \{ \forall x \in K : x \in \hat{G}_{1u} \}$$

$$= \{ \forall x \in K : \bar{x}^T \beta + c_1 \hat{\sigma}(x) \geq \lambda \}$$

$$= \{ \forall x \in K : \bar{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma}(x) \geq \lambda - \bar{x}^T \beta \}$$

$$= \{ \forall x \in K : \bar{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma}(x) \geq 0 \}$$

which gives

$$P \{ G \subseteq \hat{G}_{1u} \} = P \{ \forall x \in K : \bar{x}^T (\hat{\beta} - \beta) + c_1 \hat{\sigma}(x) \geq 0 \} = 1 - \alpha. \quad (12)$$

The combination of (11) and (12) proves the statement in (8).

The statements in (9) and (10) can be proved in a similar way, and details are omitted here to save space.
