On the Convergence of the Backward Reachable Sets of Robust Controlled Invariant Sets For Discrete-time Linear Systems

Zexiang Liu, Necmiye Ozay

Abstract—This paper considers discrete-time linear systems with bounded additive disturbances, and studies the convergence properties of the backward reachable sets of robust controlled invariant sets (RCIS). Under a simple condition, we prove that the backward reachable sets of an RCIS are guaranteed to converge to the maximal RCIS in Hausdorff distance, with an exponential convergence rate. When all sets are represented by polytopes, this condition can be checked numerically via a linear program. We discuss how the developed condition generalizes the existing conditions in the literature for controlled invariant sets of systems without disturbances (or without control inputs).

I. INTRODUCTION

Robust controlled invariant sets (RCISs) have a wide range of applications in control and verification for safety-critical systems, such as autonomous vehicles [1]–[4], robotic systems [5, 6] and power systems [7]. In many lines of works regarding RCIS, the backward reachable sets of RCIS need to be computed implicitly or explicitly. For instance, the computation of the maximal RCIS is known to be a difficult problem [8]–[10]. A common means to efficiently inner-approximate the maximal RCIS is by computing the backward reachable sets of a small but easy-to-compute RCIS [9]–[13], which is referred to as the inside-out algorithm in this work. In the context of the constrained model predictive control (MPC), the terminal set of the MPC is typically chosen as an RCIS to guarantee constraint satisfaction and recursive feasibility [14]–[16]. Then, the domain of attraction (DoA) of the MPC is exactly equal to the T-step backward reachable set of the terminal set, where T is the prediction horizon [15], [17]. More recently, inspired by MPC, a control framework called safety filter is proposed for discrete-time systems [18] and continuous-time systems [5, 19] to equip a given nominal controller with safety guarantees in a minimally invasive way. In continuous-time setup, the connection between the DoA of a safety filter and the backward reachable sets of RCISs are similar to that in MPC. In continuous-time setup, a finite-step backward reachable set of some given RCIS is constructed implicitly, to improve the scalability and reduce the conservativeness of the safety filter [5, 19].

Due to the role of the backward reachable sets of RCISs in all the aforementioned works, it is important to understand the convergence properties of the backward reachable sets of RCISs, including (i) what conditions ensure that the backward reachable sets of an RCIS converges to the maximal RCIS and (ii) how fast the backward reachable sets of an RCIS converges. In the literature, the existing works in this direction can only deal with systems without disturbances: Ahmadi and Gunluk [20] study asymptotically stable autonomous systems and provides a sufficient condition under which the k-step backward reachable set of an invariant set converges to the maximal invariant set in finite steps. The papers [9], [21]–[23] study controllable systems without disturbances and show a sufficient condition under which the k-step backward reachable set of a controlled invariant set (CIS) converges to the maximal CIS in Hausdorff distance, with an exponential convergence rate. When the system is asymptotically stabilizable without disturbances, Santis et al. [9] present a sufficient condition under which the backward reachable sets of a small CIS converges to the maximal CIS, but does not reveal the convergence rate.

As the main contribution of this work, for linear systems with both control and disturbance inputs, we develop a mild sufficient condition under which the k-step backward reachable set of an RCIS converges to the maximal RCIS in Hausdorff distance, with an exponential convergence rate. Furthermore, when all sets are represented by polytopes, this sufficient condition can be easily checked by a linear program. To the best of our knowledge, our work is the first result in the literature that shows these convergence properties for systems with additive disturbances. When restricted to systems without disturbances, the existing results in [9], [21]–[23] are shown to be special cases of our result. In addition, our result extends the results for asymptotically stabilizable systems in [9] by showing the convergence rate is exponential.

In the remainder of this work, the preliminaries of RCISs are introduced in Section II. Then, our main result is stated in Section III and proven in Section IV. After that, we compare our result with existing results in the literature in Section V and conclude the paper in Section VI. The proofs of all the minor theorems are found in Appendix.

Notation: The multiplication $AX$ of a matrix $A$ and a set $X$ is defined by $AX = \{Ax \mid x \in X\}$. The projection of a set $X \subseteq \mathbb{R}^{n+m}$ onto the first $n$ coordinates is denoted by $\pi_{1,n}(X) = \{x_1 \in \mathbb{R}^n \mid (x_1,x_2) \in X\}$. We define the distance from a point $x$ to a set $Y$ by $d(x, Y) = \inf\{\|x-y\|_2 \mid y \in Y\}$, and then define the Hausdorff distance of two sets $X$ and $Y$ by $d(X, Y) = \max(\sup_{x \in X}d(x, Y), \sup_{y \in Y}d(y, X))$. The Minkowski sum of two sets $X$ and $Y$ is denoted by $X + Y = \{x+y \mid x \in X, y \in Y\}$. When $Y = \{y\}$ is a singleton, the sum $X + Y$ is written as $X + y$ for short. Also, for a set $X$ and a point $y$, $X - y = X + (-y)$. Given a scalar $\alpha$ and a set $X$, the set $\alpha X = \{\alpha x \mid x \in X\}$. For

a subset $X$ of $\mathbb{R}^n$, the interior and closure of $X$ are denoted by $int(X)$ and $cl(X)$. The $\epsilon$-ball centered at $x$ is denoted by $B_\epsilon(x) = \{y \mid \|x - y\| < \epsilon\}$.

II. PRELIMINARIES

We consider a discrete-time linear system $\Sigma$ in form of

$$\Sigma : x(t+1) = Ax(t) + Bu(t) + Ed(t)$$

with $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$ and $d \in D \subseteq \mathbb{R}^l$. The state-input constraints of the system $\Sigma$ are specified by the safe set $S_{su}$, which contains all desired state-input pairs $(x,u)$.

Assumption 1. The safe set $S_{su}$ and the disturbance set $D$ are convex and compact.

Definition 1. A set $C \subseteq \mathbb{R}^n$ is a robust controlled invariant set (RCIS) of the system $\Sigma$ in the safe set $S_{su}$ if for all $x \in C$, there exists $u \in \mathbb{R}$ such that $(x,u) \in S_{su}$ and $Ax + Bu + ED \subseteq C$.

Given Definition 2, we define the $k$-step backward reachable set $C_k$ of $\Sigma$ in $S_{su}$ if $C_k$ contains any RCIS of $\Sigma$ in $S_{su}$.

If the disturbance set $D = \{0\}$, a set $C$ satisfying conditions in Definition 1 is just called controlled invariant set (CIS) by convention.

Definition 2. A set $X \subseteq \mathbb{R}^n$, the one-step backward reachable set $Pre_1(X,S_{su},D)$ of $X$ with respect to the system $\Sigma$, the safe set $S_{su}$ and the disturbance set $D$ is the set of states where there exists an input such that the state-input defined by

$$Pre_1(X,S_{su},D) = \{x \mid \exists u, (x,u) \in S_{su}, Ax + Bu + ED \subseteq X\}.$$  

(2)

By [24, Proposition 1], a set $C$ is an RCIS of $\Sigma$ in $S_{su}$ if and only if

$$C \subseteq Pre_1(C,S_{su},D).$$  

(3)

Furthermore, if $C$ is an RCIS of $\Sigma$ in $S_{su}$, then $Pre_1(C,S_{su},D)$ is also an RCIS of $\Sigma$ in $S_{su}$. Thus, a set $C_{max}$ is the maximal RCIS only if

$$C_{max} = Pre_1(C_{max},S_{su},D).$$  

(4)

Given Definition 2 we define the $k$-step backward reachable set $Pre_k(C_0,S_{su},D)$ of a target set $C_0$ recursively by

$$Pre_k(C_0,S_{su},D) = Pre_1(Pre_{k-1}(C_0,S_{su},D),S_{su},D).$$  

(5)

When $C_0$, $S_{su}$ and $D$ are clear in context, we denote $Pre_k(C_0,S_{su},D)$ by $C_k$ for short. Based on different choices of $C_0$, there are two standard algorithms that compute approximations of the maximal RCIS:

The outside-in algorithm [8], [10]: Let $C_0 = \pi_{[1,n]}(S_{su})$ be the projection of the safe set $S_{su}$ onto the $x$ coordinates. Recursively compute $C_k$ in (5) until the termination condition $C_k = C_{k-1}$ is satisfied.

The inside-out algorithm [9], [10]: Let $C_0$ be a known RCIS of $\Sigma$ in $S_{su}$. Recursively compute $C_k$ in (5) until the termination condition $C_k = C_{k-1}$ is satisfied or $k$ reaches a user-defined maximum step $k_{max}$.

The $k$-step backward reachable set $C_k$ in the outside-in algorithm outer-approximates the maximal RCIS [8], while the set $C_k$ in the inside-out algorithm inner-approximates the maximal RCIS. Both algorithms may fail to terminate within finite steps [10]. However, when prematurely terminated at step $k$, the set $C_k$ in the outside-in algorithm is not necessarily robust controlled invariant, and thus is less useful in control synthesis; in contrast, the set $C_k$ in the inside-out algorithm is always an RCIS. Due to this reason, the inside-out algorithm is also called an anytime algorithm [10], as users can stop the algorithm at any step $k$ and use the RCIS $C_k$ in control synthesis.

The inside-out algorithm is computationally more appealing, but the convergence properties of the inside-out algorithm are poorly studied, which motivates our work. Thus, for the remainder of this work, if not stated otherwise, we assume $C_0$ is an RCIS of $\Sigma$ within the safe set $S_{su}$, which is the setup for the inside-out algorithm.

Given $C_0$ is an RCIS, the set $\{C_k\}_{k=0}^\infty$ of finite-step backward reachable sets of $C_0$ is an expanding family of RCISs. That is, for all $k \geq 0$, $C_k$ is robust controlled invariant in $S_{su}$, and $C_{k+1} \supseteq C_k$. Thus, the limit $C_\infty$ of the $k$-step backward reachable set of $C_0$ as $k$ goes infinity is well defined:

$$C_\infty = \cup_{k=0}^\infty C_k.$$  

(6)

In this work, we also refer to the limit $C_\infty$ as the infinite-step backward reachable set of $C_0$. It is easy to see that $C_\infty$ is an RCIS within $S_{su}$.

Formally, in this work, we want to answer the following two questions:

(i) What condition ensures that the $k$-step backward reachable set $C_k$ converges to the maximal RCIS $C_{max}$ in Hausdorff distance, that is, $d(C_\infty, C_{max}) = 0$? (ii) How fast does the $k$-step backward reachable set $C_k$ converges to its limit $C_\infty$?

III. MAIN RESULT

Before we state our main result, let us first gain some intuitions from a toy example.

Example 1. Consider the 1-dimensional system

$$x(t+1) = ax(t) + u(t) + d(t),$$

(7)

with $x \in \mathbb{R}$, $u \in \mathbb{R}$ and $d \in [-d_{max},d_{max}]$. The safe set is $S_{su} = [-s_{max},s_{max}] \times [-u_{max},u_{max}]$. Define

$$c_{min} = (d_{max} - u_{max})/(1 - |a|).$$

(8)

Consider symmetric RCIS $C_0$ in form of $[-c_0,c_0]$ with $c_0 \leq s_{max}$. Then, it is easy to show that the $k$-step backward reachable set $C_k$ of $C_0$ is also symmetric, and is equal to $[-c_k,c_k]$ with

$$c_k = \min\left(\frac{c_0 - c_{min}}{|a|^k} + c_{min}, s_{max}\right).$$

(9)
Case 1: Suppose \(|\alpha| \in (0, 1)\), \(u_{\text{max}} \leq d_{\text{max}}\) and \(x_{\text{max}} > c_{\text{min}} \geq d_{\text{max}}\). For any \(c_0 \in [c_{\text{min}}, x_{\text{max}}]\), \(C_0 = [-c_0, c_0]\) is a RCIS. The maximal RCIS is \([-x_{\text{max}}, x_{\text{max}}]\).

According to (9), if we select \(c_0 \in (c_{\text{min}}, x_{\text{max}}]\), there always exists a finite \(k\) such that \(C_k\) decays to 0 exponentially fast. That is, the \(k\)-step backward reachable set \(C_k\) converges to the maximal RCIS \([-x_{\text{max}}, x_{\text{max}}]\) in finite steps. However, if we select \(c_0 = c_{\text{min}}\) then \(C_k = c_0 < x_{\text{max}}\) for all \(k \geq 0\). That is, \(C_k = C_0\) fails to converge to the maximal RCIS.

Case 2: Suppose that \(|\alpha| > 1\), \(u_{\text{max}} \geq d_{\text{max}}\), and \(x_{\text{max}} \geq c_{\text{min}} \geq d_{\text{max}}\). For any \(c_0 \in [d_{\text{max}}, c_{\text{min}}]\), \(C_0 = [-c_0, c_0]\) is an RCIS. The maximal RCIS is \([-c_{\text{min}}, c_{\text{min}}]\).

According to (9), if we select any \(c_0 \in [d_{\text{max}}, c_{\text{min}}]\), \(C_k\) converges to \(c_{\text{min}}\) in the limit. That is, the \(k\)-step backward reachable set \(C_k\) converges to the maximal RCIS in Hausdorff distance in infinite steps. The limit \(C_m = (-c_{\text{min}}, c_{\text{min}}]\) is the interior of the maximal RCIS. Furthermore, the Hausdorff distance between \(C_k\) and the maximal RCIS is

\[
d(C_k, [-c_{\text{min}}, c_{\text{min}}]) = \frac{c_{\text{min}} - c_0}{|\alpha|^k},
\]

which decays to 0 exponentially fast.

In Example 1, we observe three types of limit of \(C_k\): (i) the limit \(C_m\) is exactly equal to the maximal RCIS \(C_{\text{max}}\), (ii) \(C_m\) is a subset of \(C_{\text{max}}\), but the Hausdorff distance \(d(C_m, C_{\text{max}}) = 0\); (iii) \(C_m\) is a subset of \(C_{\text{max}}\) and the Hausdorff distance \(d(C_m, C_{\text{max}}) > 0\). Note that for the limit type (ii), even if \(C_m \subset C_{\text{max}}\), the maximal RCIS \(C_{\text{max}}\) is equal to the closure of \(C_m\) since \(d(C_m, C_{\text{max}}) = 0\). Thus, among the three types, the limit type (iii) is the least desirable one, as in this case it is impossible to obtain the maximal RCIS from the backward reachable sets of \(C_0\).

A key observation in Example 1 that distinguishes between the limit types (i), (ii) and the limit type (iii) is that if there exists a \(k\) such that \(C_k\) contains \(C_0\) in the interior, then \(C_m\) is either in type (i) or in type (ii). Indeed, in Example 1, the limit type (iii) only happens when \(C_k = C_0\) for all \(k \geq 0\). Intuitively, this observation suggests that if the backward reachable sets of \(C_0\) expand in all directions in \(\mathbb{R}^n\), then they keep expanding until they reach the maximal RCIS (that is the limit types (i) and (ii)). In other words, the limit type (iii) occurs only if the backward reachable sets of \(C_0\) only expand in certain directions, or do not expand at all (which happens in Example 1).

In terms of the convergence rate, another interesting observation in Example 1 is that the Hausdorff distance between \(C_k\) and the maximal \(C_{\text{max}}\) decays to 0 at least exponentially fast for the limit types (i) and (ii).

Next, we state the main result of this work, which shows that the observations made in Example 1 actually hold for any linear systems of the form (1).

**Theorem 1.** Under Assumption 7, suppose that \(C_0\) is a compact and convex RCIS of the system \(\Sigma\) in \(S_{\text{max}}\). If \(C_0\) is contained in the interior of \(C_{k_0}\), for some \(k_0 > 0\), then \(C_k\) converges to the maximal RCIS \(C_{\text{max}}\) in Hausdorff distance, and there exists integers \(N_0 \geq 0\), \(N > 0\) and scalars \(c > 0\), \(a \in (0, 1)\) such that the Hausdorff distance between \(C_{N_0+kN}\) and \(C_{\text{max}}\) satisfies

\[
d(C_{N_0+kN}, C_{\text{max}}) \leq ca^k.
\]

That is, the Hausdorff distance \(d(C_{N_0+kN}, C_{\text{max}})\) decays to 0 exponentially fast as \(k\) goes to infinity.

Note that the bound in (11) only holds for indices \(\{N_0 + kN\}_{k=0}^\infty\) increasing by an interval of \(N\). But, due to the fact that \(d(C_k, C_{\text{max}})\) is monotonically non-increasing over \(k\), the inequality in (11) implies for all \(k \geq 0\),

\[
d(C_{N_0+k}, C_{\text{max}}) \leq c(a^{\frac{1}{N}})^kN+1 = (ca^{-1+1/N})d^kN.
\]

Hence, by Theorem 1 and (12), the \(k\)-step backward reachable set \(C_k\) converges to the maximal RCIS \(C_{\text{max}}\) in Hausdorff distance exponentially fast whenever \(C_0\) is contained in the interior of \(C_{k_0}\) for some \(k_0 > 0\). This result validates the two key observations we have in Example 1.

When \(C_0\) and \(C_k\) are represented by polytopes, the condition \(C_0 \subseteq \text{int}(C_k)\) can be numerically checked by a linear program. Suppose that \(C_0 = \{x \mid H_1x \leq h_1\}\) and \(C_k = \{x \mid H_2x \leq h_2\}\) for some \(H_i, h_i\) in appropriate dimensions, \(i = 1, 2\), and \(x_0\) is any interior point of \(C_k\). We construct the following linear program to check if \(C_0 \subseteq \text{int}(C_k)\):

\[
\gamma^* = \min_{\gamma \geq 0, \Lambda} \gamma
\]

subject to \(\Lambda H_1 = H_2\)

\[
\Lambda(h_1 - H_1x_0) \leq \gamma(h_2 - H_2x_0).
\]

According to [25, Lemma 1], \(\gamma^*\) in (13) is less than 1 if and only if \(C_0 \subseteq \text{int}(C_k)\) if and only if \(k_0 \leq k\).

Next, recall that \(C_m\) in (9) is the limit of the \(k\)-step backward reachable set \(C_k\) as \(k\) goes to infinity. When \(k_0\) in Theorem 1 exists, it is obvious that \(C_0\) is contained by the interior \(\text{int}(C_m)\) of \(C_m\), since \(C_m\) is a subset of \(C_0\). But conversely, if \(C_0 \subseteq \text{int}(C_m)\), does there always exist a finite \(k_0\) such that \(C_0 \subseteq \text{int}(C_{k_0})\)? It turns out that those two conditions are equivalent, shown by the following theorem:

**Theorem 2.** Under the same conditions of Theorem 1, \(C_0\) is contained in the interior of \(C_{k_0}\) for some finite \(k_0 > 0\) if and only if \(C_0\) is contained in the interior of \(C_m\) in (9).

Finally, the readers may wonder what happens if \(k_0\) in Theorem 1 does not exist, or equivalently \(C_0 \not\subseteq \text{int}(C_m)\). In Example 1 the limit type (iii) occurs when \(k_0\) does not exist. However, there are examples where the limit type (i) and (ii) occur even if a finite \(k_0\) does not exist. Thus, the existence of \(k_0\) is only a sufficient condition for the convergence of the backward reachable set \(C_k\) to the maximal RCIS. When the system is disturbance-free (that is \(D = \{0\}\)), the existence of \(k_0\) is guaranteed if \((A, B)\) is asymptotically stable and \(0 \in \text{int}(C_0)\), or if \((A, B)\) is controllable and \(0 \in \text{int}(S_{\text{ca}})\). A more in-depth discussion for results of disturbance-free systems can be found in Section 7.

---

*This is a sample text to illustrate the process.*
IV. PROOF OF THE MAIN RESULT

In this section, we present the main ideas in the proof of Theorem 1. First, according to a fixed-point theorem [26, Theorem 12], given a compact convex RCIS $C_0$ in $S_{\text{sat}}$, there always exists a stationary point $(x_e, u_e, d_e) \in S_{\text{sat}} \times D$ such that $x_e \in C_0$ and $Ax_e + Bu_e + Ed_e = x_e$. Without loss of generality, we assume that the stationary point $(x_e, u_e, d_e)$ is the origin of the state-input-disturbance space and thus $0 \in C_0$ and $0 \in S_{\text{sat}} \times D$ for the remainder of this section. Also, by Theorem 2, we convert the condition on the existence of the infinite-step backward reachable set $C_0$ into the following equivalent assumption.

**Assumption 2.** The set $C_0$ is a compact convex RCIS of $\Sigma$ in $S_{\text{sat}}$ and is contained by the interior $\text{int}(C_0)$ of the infinite-step backward reachable set $C_{\infty}$ in $\Sigma$.

Based on Assumption 2, the proof of Theorem 1 contains two steps: The first step is to show that the closure $c_l(C_{\infty})$ of the limit $C_{\infty}$ is equal to the maximal RCIS $C_{\infty}$, that is to prove the following theorem:

**Theorem 3.** Under Assumptions 1 and 2, the closure of $C_{\infty}$ in $\Sigma$ is the maximal RCIS $C_{\infty}$, that is $c_l(C_{\infty}) = C_{\infty}$.

**Sketch proof.** Note that the maximal RCIS $C_{\infty}$ is bounded due to Assumption 1. Since $C_0 \subseteq \text{int}(C_{\infty})$ and $C_{\infty}$ is bounded, intuitively, we can find a small enough $\alpha > 0$ such that the set $C(\alpha) = (1 - \alpha)C_0 + \alpha C_{\infty}$ is contained in $\text{int}(C_{\infty})$. Due to the linearity of the system, it can be shown that the infinite-step backward reachable set of $C(\alpha)$ contains $(1 - \alpha)C_0 + \alpha C_{\infty}$. Then, the key to prove Theorem 3 is to realize that for any set $C' \subseteq \text{int}(C_{\infty})$, the infinite-step backward reachable set of $C'$ is contained by $C_{\infty}$. Thus, for some $\alpha > 0$, we have $(1 - \alpha)C_0 + \alpha C_{\infty} \subseteq C_{\infty} \subseteq C_{\infty}$. That implies $C_{\infty} = c_l(C_{\infty})$. The complete proof can be found in Appendix.

The second step is to show that the Hausdorff distance between $C_0$ and the maximal RCIS $C_{\infty}$ decays to 0 exponentially fast when $C_0 \subseteq \text{int}(C_{\infty})$. We first introduce an extended notion of $\lambda$-contractive sets [27]:

**Definition 3.** Given a scalar $\lambda > 0$, a set $X$ is called $k$-step $\lambda$-contractive if $X$ is contained by the $k$-step backward reachable set of $\lambda X$, that is, $\text{Pre}_X^k(\lambda X, S_{\text{sat}}, D) \supseteq X$.

By definition, a set $X$ is $k$-step $\lambda$-contractive if the system can go from any state in $X$ to some state in $\lambda X$ in $k$ steps without violating any safety constraints. Under Assumptions 1 and 2, the closure of the infinite-step backward reachable set $c_l(C_{\infty})$ always contains $C_{\infty}$, which is shown by the following theorem.

**Theorem 4.** Under Assumptions 1 and 2, there exist an integer $N > 0$ and scalars $\gamma \in (0, 1], \lambda \in [0, 1)$ such that $\gamma c_l(C_{\infty})$ is $N$-step $\lambda$-contractive. Furthermore, there exists a finite integer $N_0 \geq 0$ such that $\text{Pre}_X^{N_0}(C_0, S_{\text{sat}}, D) \supseteq \lambda \gamma c_l(C_{\infty})$.

**Sketch proof.** Since $C_{\infty}$ contains $C_0$ in the interior and $C_{\infty}$ is convex, there exists positive scalars $\beta_0$ and $\beta_1$, with $0 < \beta_1 < \beta_2 < 1$, such that $C_0 \subseteq \beta_0 c_l(C_{\infty}) \subseteq \beta_1 c_l(C_{\infty}) \subseteq \text{int}(C_{\infty})$. Since $\beta_1 c_l(C_{\infty})$ is in the interior of $C_{\infty}$ and the $k$-step backward reachable set of $C_0$ converges to $C_{\infty}$, it can be proven that there exists a finite $N$ such that $C_N \supseteq \beta_1 c_l(C_{\infty})$. Since $\beta_0 c_l(C_{\infty})$ contains $C_0$, the $N$-step backward reachable set of $\beta_0 c_l(C_{\infty})$ contains $C_N$ and thus contains $\beta_1 c_l(C_{\infty})$. That implies $\beta_1 c_l(C_{\infty})$ is a $N$-step $(\beta_0/\beta_1)$-contractive set. By assigning $\gamma = \beta_1$, $\lambda = \beta_1/\beta_0$ and $N_0 = N$, the statement in Theorem 4 is proven. A complete proof can be found in Appendix.

By Theorems 3 and 4, we show that $\gamma c_l(C_{\infty}) = \gamma C_{\infty}$ is $N$-step $\lambda$-contractive. Note that a $k$-step $\lambda$-contractive set $X$ is not necessarily an RCIS unless $k = 1$ and $0 \in X$. Thus, $\gamma C_{\infty}$ may not be an RCIS.

Recall that our goal in the second step of proving Theorem 1 is to show the convergence rate of the $k$-step backward reachable set $C_k$ to $C_{\infty}$. So how is $\gamma C_{\infty}$ being $k$-step $\lambda$-contractive set related to the convergence rate of backward reachable sets? Let $C$ be an RCIS of $\Sigma$ in $S_{\text{sat}}$. It turns out that if there exists a factor $\gamma \in (0, 1]$ such that the scaled set $\gamma C$ is $N$-step $\lambda$-contractive for some $N$ and $\lambda \in [0, 1)$, then the $k$-step backward reachable set of $\lambda \gamma C$ approaches to $C$ exponentially fast as $k$ increases. The proof of this statement is enabled by the following theorem.

**Theorem 5.** Under Assumption 1, for any convex RCIS $C$ of $\Sigma$ in $S_{\text{sat}}$, suppose that there exist $\gamma \in (0, 1), N$ and $\lambda \in [0, 1)$ such that $\gamma C$ is $N$-step $\lambda$-contractive, that is

$$\text{Pre}_N^N(\lambda \gamma C, S_{\text{sat}}, D) \supseteq \gamma C.$$  (14)

Then, for any scalar $\xi$ with $1 > \xi \geq \lambda \gamma$,

$$\text{Pre}_N^N(\xi C, S_{\text{sat}}, D) \supseteq g(\xi)C,$$  (15)

where

$$g(\xi) = \frac{1 - \gamma}{1 - \lambda \gamma} \xi + \frac{1 - \lambda}{1 - \lambda \gamma} \geq \xi.$$  (16)

For any $C$ satisfying the conditions in Theorem 5 (15) implies that the $N$-step backward reachable set of $\lambda \gamma C$ expands at least to $g(\lambda C)$.

By applying Theorem 5 $k$ times, we obtain that

$$\text{Pre}_N^{kN}(\lambda \gamma C, S_{\text{sat}}, D) \supseteq g^k(\lambda \gamma)C,$$  (17)

where $g^k(\cdot) = g(g(\ldots))$ is the function that composes $g(\cdot)$ for $k$ times. According to Theorems 3 and 4, $C$ in (17) can be replaced by $C_{\infty}$. That is, for $\gamma, N$ and $\lambda$ in Theorem 4

$$\text{Pre}_N^{kN}(\lambda \gamma C_{\infty}, S_{\text{sat}}, D) \supseteq g^k(\lambda \gamma)C_{\infty}.$$  (18)

By Theorem 4, there exists $N_0$ such that the $N_0$-step backward reachable set $C_{N_0}$ of $C_0$ contains $\lambda \gamma C_{\infty}$. Then, by (18),

$$C_{\infty} \supseteq C_{N_0 + kN} \supseteq \text{Pre}_N^{kN}(\lambda \gamma C_{\infty}, S_{\text{sat}}, D) \supseteq g^k(\lambda \gamma)C_{\infty}.$$  (19)

The inclusion relation in (19) implies that the Hausdorff distance between $C_{N_0 + kN}$ and the maximal RCIS $C_{\infty}$ is bounded by

$$d(C_{N_0 + kN}, C_{\infty}) \leq (1 - g^k(\lambda \gamma)) \sup_{x \in C_{\infty}} \|x\|_2.$$  (20)

1See Appendix A for a detailed discussion.
Since \(g(\cdot)\) in (16) is affine, it is easy to derive that
\[
1 - g^k(\lambda \gamma) = \left( \frac{1 - \gamma}{1 - \lambda \gamma} \right)^k (1 - \lambda \gamma).
\] (21)
Combining (20) and (21), we have
\[
d(C_{N_0+kN}, C_{\text{max}}) \leq cd^k,
\]
where \(c = (1 - \lambda \gamma) \sup_{x \in C_{\text{max}}} \|x\|_2\) and \(a = (1 - \gamma)/(1 - \lambda \gamma)\). With \(\gamma \in (0,1), \lambda \in [0,1),\) it is easy to check that \(a \in [0,1)\). Since \(C_{\text{max}}\) is bounded, \(c\) is finite. Thus, the Hausdorff distance between \(C_{N_0+kN}\) and \(C_{\text{max}}\) decays to 0 exponentially fast as \(k\) goes to infinity. That completes the proof of Theorem 1.

V. DISCUSSION

In this section, we compare our result with the existing ones in [9], [21]–[23]. Here we adopt the notation in [9], [23] and call a set \(X\) a \(C\)-set if \(X\) is convex, compact and contains 0 in the interior. Note that the results in [9], [21]–[23] are all based on the condition that the disturbance set \(D = \{0\}\) and \(S_{\text{max}}\) is a \(C\)-set. Hence, we assume that the above condition holds for the remainder of this section.

First, [9], [22], [23] identify the two sufficient conditions under which the \(k\)-step backward reachable set \(C_k\) converges to the maximal CIS in Hausdorff distance. The first sufficient condition [9], [22], [23] is that \((A, B)\) is controllable and \(C_0 = \{0\}\); the second one [9, Proposition 30] is that \((A, B)\) is asymptotically stable and \(C_0\) is a controlled invariant \(C\)-set. When the first sufficient condition is satisfied, [9], [23] show that \(C_0 = \{0\}\) also satisfies the conditions in Theorem 1. When the second sufficient condition is satisfied, the corresponding \(C_0\) may not satisfy the condition in Theorem 1. However, the proof of [9, Proposition 30] shows that \(C_0\) must contain a smaller \(C\)-set that satisfies the conditions in Theorem 1. Thus, both of the sufficient conditions are corollaries of our result.

Though [9], [22], [23] prove the convergence of \(C_k\), none of those works show the convergence rate of \(C_k\). To our best knowledge, [21] is the only work that shows the convergence rate of \(C_k\), under the condition that \((A, B)\) is controllable and \(C_0 = \{0\}\) (the first sufficient condition above). Originally [21] derives the convergence rate in a different metric. But by converting the metric in [21] to Hausdorff distance, we can show that the convergence rate of \(C_k\) in [21] is equivalent to the exponential convergence in Hausdorff distance proven in this work. That is, under the first sufficient condition in the previous paragraph, our result coincides with the result in [21].

VI. CONCLUSION

In this work, we consider linear systems with disturbance and show a sufficient condition under which the \(k\)-step backward reachable set of RCISs converges to the maximal RCIS exponentially fast. When all sets are represented by polytopes, this sufficient condition can be numerically checked via the linear program in [13]. When restricted to disturbance-free systems, our result implies the existing results in [9], [21]–[23].

In terms of applications, our result provides convergence guarantees for inside-out algorithm (and its variants) [9]–[13], [22], and sheds lights on novel analysis for RCIS-based control synthesis algorithms. For instance, in constrained model predictive control (MPC) equipped with a controlled invariant terminal set [14], our results imply that under mild conditions, the DoA of MPC enlarges to the maximal DoA exponentially fast as the prediction horizon \(T\) increases, which provides new insights for selecting the prediction horizon \(T\). Moreover, if parameters \(N_0, N, a\) and \(c\) in Theorem 1 are known, we can quantitatively evaluate the Hausdorff distance between the DoA of MPC with respect to any given \(T\) and the maximal DoA via (11). The algorithms for estimating parameters \(N_0, N, a\) in Theorem 1 will be part of our future work.

APPENDIX

A. On the existence of stationary points

[26, Theorem 12] only consider disturbance-free systems with decoupled safe set $S_{\text{df}} = X \times U$ for a convex compact $X \subseteq \mathbb{R}^n$ and a closed convex $U \subseteq \mathbb{R}^m$. To apply [26, Theorem 12] to our setting, given the system $\Sigma$ of the form (1), we construct the disturbance-free system $\Sigma' :=

\begin{align*}
    x(t+1) &= A x(t) + B u(t) + E v_1(t) + v_2(t), \quad (22)
\end{align*}

where $(x,u)$ is the state and $v_1, v_2$ are two inputs of the system $\Sigma'$. Given a compact convex RCIS $C_0$ of $S$ in $\Sigma$, construct the set $C_0'$ as

$$C_0' = \{ (x,u) \in S_{\text{df}} | x \in C_0, \exists d \in D, Ax + Bu + Ed \in C_0 \}. \quad (23)$$

It is easy to check that $C_0'$ is a compact convex controlled invariant set [26] of the system $\Sigma'$ in the decoupled safe set $S_{\text{df}} \times \mathbb{R}^m \times D$. Then, by [26, Theorem 12], there exists $(x_0,u_0) \in C_0'$, $v_1, v_2 \in \mathbb{R}^n$ and $d \in D$ such that

$$\begin{align*}
    x_{e} &= A x_e + B u_e + E v_1, \\
    u_{e} &= v_2. \quad (24)
\end{align*}$$

Define $d_e = v_2$. By (24), $x_{e} = Ax_e + Bu_e + Ed_e$. By construction of $C_0'$, we have $x_e \in C_0'$ and $(x_e, u_e) \in S_{\text{df}}$.

B. Proofs of Theorems

The following lemmas reveal properties of the backward reachable sets, which are crucial for proving Theorems.

Lemma 1. For a linear system $\Sigma$ in form of (1),

$$\begin{align*}
    \text{Pre}_\Sigma(x_{1} + x_{2}, S_{\text{df}}) &\supseteq \text{Pre}_\Sigma(x_{1}, S_{\text{df}}) + \text{Pre}_\Sigma(x_{2}, S_{\text{df}}), \quad (25)
\end{align*}$$

Proof. Let $x_i \in \text{Pre}_\Sigma(x_{1} + x_{2}, S_{\text{df}})$ for $i = 1, 2$. Then, there exists $u_i$ such that $(x_i, u_i) \in S_{\text{df}}$ and $Ax_i + Bu_i + D \subseteq X_i$, for $i = 1, 2$. Thus, we have

$$\begin{align*}
    (x_1, u_1) + (x_2, u_2) &\subseteq (x_1 + x_2, u_1 + u_2), \quad (26)
    A(x_1 + x_2) + B(u_1 + u_2) + D_1 + D_2 \subseteq X_1 + X_2. \quad (27)
\end{align*}$$

Thus, $x_1 + x_2 \in \text{Pre}_\Sigma(x_1 + x_2, S_{\text{df}}) + \text{Pre}_\Sigma(x_1, S_{\text{df}}) + \text{Pre}_\Sigma(x_2, S_{\text{df}})$. \hfill \square

Lemma 2. For a linear system $\Sigma$ in form of (1), if $X, S_{\text{df}}$ and $D$ are convex, then for any $a \in [0, 1], b \in [0, 1]$ and $k \geq 1$,

$$\begin{align*}
    \text{Pre}_\Sigma^k(x, S_{\text{df}}, D) &\supseteq \text{Pre}_\Sigma^k(ax, bS_{\text{df}}, bD), \quad (28)
\end{align*}$$

Proof. For any convex set $C, C = aC + (1-a)C$ for any $a \in [0, 1]$. Thus, by Lemma 1, $C = k aC + (1 - k)aC$. \hfill \square

Lemma 3. For a linear system $\Sigma$ in form of (1) and any $a \geq 0$,

$$\begin{align*}
    \text{Pre}_\Sigma(ax, aS_{\text{df}}, aD) &\supseteq \text{Pre}_\Sigma(x, S_{\text{df}}, D). \quad (30)
\end{align*}$$

Proof. Let $x \in \text{Pre}_\Sigma(x, S_{\text{df}}, D)$. Then, there exists $u$ such that $(x,u) \in S_{\text{df}}$ and $Ax + Bu + D \subseteq X$. Thus, $(ax, au) \in aS_{\text{df}}$ and $(Aax + Aau + aD \subseteq ax)$. That is, $ax \in \text{Pre}_\Sigma(ax, aS_{\text{df}}, aD)$. Therefore, $\text{Pre}_\Sigma(x, S_{\text{df}}, D) \supseteq \text{Pre}_\Sigma(ax, aS_{\text{df}}, aD)$.

Next, let $ax \in \text{Pre}_\Sigma(ax, aS_{\text{df}}, aD)$. Then, there exists $au$ such that $(ax, au) \in aS_{\text{df}}$ and $Aax + Aau + aD \subseteq ax$. Thus, $(x,u) \in S_{\text{df}}$ and $(Ax + Bu + D \subseteq X)$. That is, $x \in \text{Pre}_\Sigma(x, S_{\text{df}}, D)$. Therefore, $\text{Pre}_\Sigma(ax, aS_{\text{df}}, aD) \supseteq \text{Pre}_\Sigma(x, S_{\text{df}}, D)$. \hfill \square

Lemma 4. Let $\{C_i\}_{i=0}^\infty$ be an expanding family of nonempty compact convex sets. That is, $C_i \subseteq C_{i+1}$ for any $i, j$ such that $i \leq j$. Suppose that $\text{int}(C_i) \neq \emptyset$ for all $i \geq i_0$ for some $i_0 \geq 0$, and $C_{i_0} = \cup_{i=0}^{i_0} C_i$ is bounded. Then, for any closed set $U \subseteq \text{int}(C_{i_0})$, there exists $i$ such that $C_i \supseteq U$.

Proof. Without loss of generality, we assume $i_0 = 0$. Since $C_i$ is convex and compact, it is easy to check that $\text{cl}(\text{int}(C_i)) = C_i$.

Define $\hat{C}_m = \lim_{k \to \infty} \cup_{i=0}^k \text{int}(C_i)$. Thus, $\hat{C}_m$ is an open convex set. Note that

$$\text{cl}(C_m) \supseteq \text{cl}(\hat{C}_m) \supseteq \text{cl}(\text{int}(C_i)) = C_i, \forall i \geq 0. \quad (31)$$
Thus,
\[
cl(C_\infty) \supseteq cl(\tilde{C}_\infty) \supseteq \lim_{k \to \infty} \bigcup_{i=0}^k C_i = C_{\infty}.
\] (32)

Thus, \(cl(C_\infty)\) is the closure of \(\tilde{C}_\infty\). By convexity of \(C_\infty\), \(\tilde{C}_\infty\) is the interior of \(cl(C_\infty)\), and also the interior of \(C_\infty\).

Next, let \(U\) be a closed subset of \(int(C_\infty) = \tilde{C}_\infty\). Since \(C_\infty\) is bounded, \(U\) is compact. Also, since \(U \subseteq \tilde{C}_\infty = \bigcup_{i=0}^\infty int(C_i)\), \(\{int(C_i)\}_{i=0}^\infty\) forms an open cover of \(U\). By compactness, there exists a finite subcover \(\{C_k\}_{k=0}^K\) of \(U\) for some \(K \geq 0\). Then, \(U \subseteq int(C_k)\).

**Lemma 5.** Let \(X\) be a nonempty compact convex set in \(\mathbb{R}^n\). Under Assumption \[\text{Pre}_2\] \(Pre_2(X,S_\infty,D)\) is convex and compact.

**Proof.** Define \(C_{\infty} = \{(x,u) \in S_\infty \mid Ax + Bu + ED \subseteq X\}\). By definition of backward reachable set, \(Pre_2(X,S_\infty,D) = \pi_1[\eta](C_{\infty})\). For now, we assume that \(C_{\infty}\) is compact and convex. Since projection \(\pi_1[\eta](\cdot)\) is continuous and \(C_{\infty}\) is compact, \(Pre_2(X,S_\infty,D)\) is compact. Since the projection of a convex set is convex, \(Pre_2(X,S_\infty,D)\) is convex. It is left to show the convexity and compactness of \(C_{\infty}\).

We first show that \(C_{\infty}\) is convex. Let \((x_1,u_1),(x_2,u_2)\) be two points in \(C_{\infty}\) and \(\alpha\) be constant in \((0,1)\). Denote \((x,u) = \alpha(x_1,u_1) + (1-\alpha)(x_2,u_2)\). Since \(S_\infty\) is convex, \((x,u)\) is in \(S_\infty\). For any \(d \in D\) and \(i \in \{1,2\}\), \(x_i^+ = Ax_i + Bu_i + ED \in X\). Since \(X\) is convex, for the same \(d \in D\), \(Ax + Bu + Ed \subseteq \alpha x_1^+ + (1-\alpha)x_2^+\) is in \(X\). Thus, \((x,u) \in C_{\infty}\). That is, \(C_{\infty}\) is convex.

Next, we show that \(C_{\infty}\) is compact. Let \{(x_n,u_n)\}_{n=1}^\infty\) be an arbitrary convergent sequence in \(C_{\infty}\). Suppose that \((x_n,u_n) \rightarrow (x,u)\). Since \(S_\infty\) is compact, \((x,u) \in S_\infty\). For any \(d \in D\), \(Ax_n + Bu_n + Ed \rightarrow Ax + Bu + Ed\). Since \(X\) is compact, \(Ax + Bu + Ed \subseteq X\). Since \((x,u) \in C_{\infty}\), \(Ax + Bu + Ed \subseteq \alpha x_1^+ + (1-\alpha)x_2^+\) is in \(X\). Thus, \((x,u) \in C_{\infty}\). That is, \(C_{\infty}\) is compact.

**Lemma 6.** Suppose Assumption \[\text{Pre}_2\] holds. Let \(C_0\) be a compact convex RCIS of \(\Sigma\) in \(S_\infty\). Define \(C_k = Pre_2^k(C_0,S_\infty,D)\) and \(C_\infty = \bigcup_{k=1}^\infty C_k\). Then, \(C_\infty\) satisfies the following properties:

(a) \(\{C_k\}_{k=1}^\infty\) is an expanding family of compact convex RCISs.

(b) \(C_\infty\) is bounded and \(C_k \subseteq \pi_1[\eta](S_\infty)\) for all \(k \geq 0\), \(C_\infty\) is bounded. Let \(x_1\) and \(x_2\) be two points in \(C_\infty\). Since \(\{C_k\}_{k=1}^\infty\) is an expanding family of sets and \(C_\infty = \bigcup_{k=1}^\infty C_k\), there exists \(k_0\) such that \(x_1,x_2 \in C_{k_0}\). According to (a), \(C_{k_0}\) is convex. Thus, any convex combination of \(x_1\) and \(x_2\) is in \(C_{k_0} \subseteq C_\infty\). Hence, \(C_\infty\) is convex.

(c) Since \(int(C_\infty)\) is nonempty, we can fit a small hypercube in the interior of \(C_\infty\). By definition of \(C_\infty\), each vertex of this hypercube is contained by \(C_k\) for some finite \(k\). Since the hypercube has finitely many vertices, there exists a finite \(k_0\) such that \(C_{k_0}\) contains all the vertices of the hypercube. Since \(C_{k_0}\) is convex, \(C_{k_0}\) contains the hypercube and thus has nonempty interior.

(d) Suppose that for all \(\varepsilon > 0\), \(C + B_{\varepsilon}(0) \not\subseteq C_\infty\). Then there exists \(x_0 \in C\) such that \(B_{1/\varepsilon}(x_0) \not\subseteq C_\infty\). Since \(C_\infty\) is compact, there exists a convergent subsequence \(\{x_n\}_{n=1}^\infty\) such that \(x_n \rightarrow x\) for some \(x \in C\). Since \(C_\infty\) is contained by \(C_{\infty}\), there exists \(\varepsilon' > 0\) such that \(B_{\varepsilon'}(x) \subseteq C_{\infty}\). Since \(n_i \rightarrow \infty\) and \(x_n \rightarrow x\), there exists \(\varepsilon' > 0\) such that \(1/\varepsilon' < \varepsilon'/2\) and \(||x_n-x||_2 < \varepsilon'/2\). Thus, \(B_{1/\varepsilon'}(x_n) \subseteq B_{\varepsilon'}(x) \subseteq C_{\infty}\). However, by construction, \(B_{1/\varepsilon'}(x_n) \not\subseteq C_{\infty}\). Hence, contradiction! Thus, there exists \(\varepsilon > 0\) such that \(C + B_{\varepsilon}(0) \subseteq C_{\infty}\).

**Proof of Theorem 2** If \(C_0\) is contained in the interior of \(C_{k_0}\) for some \(k_0 > 0\), it is trivial that \(C_0\) is contained in the interior of \(C_{\infty}\). Now suppose that \(C_0\) is contained in the interior of \(C_{\infty}\). By Lemma 6(d), there exists \(\varepsilon > 0\) such that \(cl(C_0 + B_{\varepsilon}(0)) \subseteq int(C_{\infty})\). Also, by Lemma 6(c), there exists \(k_0\) such that \(int(C_{k_0})\) is nonempty. Thus by Lemma 4, there exists \(k\) such that \(C_k \supseteq cl(C_0 + B_{\varepsilon}(0))\). For the same \(k\), it is clear that \(C_0 \subseteq int(C_k)\).

**Proof of Theorem 3** We first show that there exists a constant \(\alpha \in (0,1)\) such that \(\alpha C_{\infty} + (1-\alpha)C_0\) is contained by the interior of \(C_{\infty}\). Since \(C_0\) is contained in the interior of \(C_{\infty}\), by Lemma 6 there exists \(\varepsilon > 0\) such that \(C_0 + B_{\varepsilon}(0) \subseteq C_{\infty}\). Then, \(C_0 + B_{\varepsilon/2}(0)\) is in the interior of \(C_{\infty}\). Since \(S_\infty\) is compact, \(C_{\infty}\) is bounded, and thus there exists \(\varepsilon > 0\) such that \(\alpha C_{\infty} \subseteq B_{\varepsilon/2}(0)\). Thus, \(C_0 + \alpha C_{\infty} \subseteq C_{\infty}\). Since \(0 \in C_0, (1-\alpha)C_0 + \alpha C_{\infty} \subseteq C_0 + \alpha C_{\infty} \subseteq C_{\infty}\). Since both \(C_0\) and \(C_{\infty}\) are compact and convex, \(\alpha C_{\infty} + (1-\alpha)C_0\) is compact and convex. By Lemmas 4 and 6 since \(\alpha C_{\infty} + (1-\alpha)C_0\) is a closed subset of \(int(C_{\infty})\), there exists \(k_0\) such that \(\alpha C_{\infty} + (1-\alpha)C_0 \subseteq C_{k_0}\).

We denote \(\overline{C_0} = \alpha C_{\infty} + (1-\alpha)C_0\). Since \(C_0\) and \(C_{\infty}\) are RCISs, it is easy to check that \(\overline{C_0}\) is also an RCIS in \(S_\infty\). Define \(\overline{C_k} = Pre_2^k(\overline{C_0},S_\infty,D)\). Then, by Lemmas 4 and 3

\[
\overline{C_k} = Pre_2^k(\overline{C_0},S_\infty,D) \supseteq \alpha Pre_2^k(C_\infty,S_\infty,D) + C_0
\]

(33) and

\[
\alpha C_{\infty} + (1-\alpha)C_k
\]

(34)
Define $\overline{C}_n = \bigcup_{k=0}^{\infty} C_k$. Then,
\begin{align*}
\overline{C}_n &\supseteq \bigcup_{k=0}^{\infty} (\alpha C_{\text{max}} + (1 - \alpha)C_k) \\ &= \alpha C_{\text{max}} + (1 - \alpha) \bigcup_{k=0}^{\infty} C_k \\ &= \alpha C_{\text{max}} + (1 - \alpha) C_n.
\end{align*}
(35)
(36)
(37)

Since by construction of $k_0$, $\overline{C}_0 \subseteq C_{k_0}$,
\begin{equation}
\overline{C}_n \subseteq \bigcup_{k=0}^{\infty} \text{Pre}_\gamma^N (C_{k_0}, S_{\text{max}}, D) = \bigcup_{k=1}^{\infty} C_{k_0+k} = C_n.
\end{equation}
(38)

Thus, by (37) and (38),
\begin{align*}
\alpha C_{\text{max}} + (1 - \alpha) C_n &\subseteq \overline{C}_n \subseteq C_n \\
cl(\alpha C_{\text{max}} + (1 - \alpha) C_n) &\subseteq cl(\overline{C}_n) \subseteq cl(C_n).
\end{align*}
(39)
(40)

Since $C_{\text{max}}$ and $cl(C_n)$ are compact, $\alpha C_{\text{max}} + (1 - \alpha) cl(C_n)$ is compact. Thus,
\begin{equation}
cl(\alpha C_{\text{max}} + (1 - \alpha) C_n) \subseteq \alpha cl(C_n) + (1 - \alpha) cl(C_n).
\end{equation}
(41)

Let $x \in \alpha C_{\text{max}} + (1 - \alpha) cl(C_n)$. Then, there exist points $x_1 \in C_{\text{max}}$ and $x_2 \in cl(C_n)$ such that $x = \alpha x_1 + (1 - \alpha)x_2$. Since $x_2 \in cl(C_n)$, there exists $(x_2, k) \subseteq n$ such that $x_2, k \rightarrow x_2$. Since $\alpha x_1 + (1 - \alpha)x_2, k \in \alpha C_{\text{max}} + (1 - \alpha) C_{\text{max}}$ and $\alpha x_1 + (1 - \alpha)x_2, k \rightarrow x_2, x \in cl(\alpha C_{\text{max}} + (1 - \alpha) C_n)$ and thus $cl(\alpha C_{\text{max}} + (1 - \alpha) C_n)$ is equal to $\alpha C_{\text{max}} + (1 - \alpha) cl(C_n)$. Hence, (40) implies
\begin{equation}
\alpha C_{\text{max}} + (1 - \alpha) cl(C_n) \subseteq cl(C_n) = \alpha cl(C_n) + (1 - \alpha) cl(C_n).
\end{equation}
(42)

Since $cl(C_n)$ is convex and compact, by order cancellation theorem [28, Theorem 4], (41) implies $\alpha C_{\text{max}} \subseteq cl(C_n)$ and thus $C_{\text{max}} \subseteq cl(C_n)$. Also, since $C_{\text{max}}$ is the maximal RCIS, $C_n \subseteq C_{\text{max}}$. Thus, $C_n = cl(C_n)$. □

**Proof of Theorem 4.** Let $\beta_0$ be the infimum $\beta$ such that $C_0 \subseteq \beta cl(C_n)$. We first want to show that $\beta_0 < 1$. By Lemma 6, $cl(C_n)$ is a compact and convex set and there exists $\epsilon > 0$ such that $C_0 + B_\epsilon(0) \subseteq cl(C_n)$. Since $cl(C_n)$ is bounded, there exists $\alpha > 0$ such that $\alpha cl(C_n) \subseteq B_\epsilon(0)$. Thus, $C_0 + \alpha cl(C_n) \subseteq cl(C_n) = \alpha cl(C_n) + (1 - \alpha) cl(C_n)$. Since $\alpha cl(C_n)$ is a nonempty compact set and $(1 - \alpha) cl(C_n)$ is convex, by the order cancellation theorem (Theorem 4 in [28]), $C_0 \subseteq (1 - \alpha) cl(C_n)$. Thus, $\beta_0 \leq 1 - \alpha < 1$.

Pick $\beta_1$ in $(\beta_0, 1)$. For now, let us assume that there exists a $N > 0$ such that
\begin{equation}
C_N = \text{Pre}_\gamma^N (C_0, S_{\text{max}}, D) \supseteq \beta_1 cl(C_n).
\end{equation}
(43)

Then, $\text{Pre}_\gamma^N (\beta_1 cl(C_n), S_{\text{max}}, D) \supseteq \beta_1 cl(C_n)$. Let $\lambda = \beta_0/\beta_1$. Then, $\beta_1 cl(C_n)$ is an $N$-step $\lambda$-contractive set.

Now it is left to show that there exists a $N > 0$ such that (42) holds. It is easy to show that (i) $\{C_k\}_k$ is an expanding family of convex compact sets. (ii) Since $C_{\text{max}} = \bigcup_{n=1}^{\infty} C_k$ contains 0 in the interior, by Lemma 6 (c), there exists $k_0$ such that $C_{k_0}$ contains 0 in the interior. (iii) $C_n$ is bounded since $S_{\text{max}}$ is bounded. Finally, since $cl(C_n)$ contains 0 in the interior, $cl(C_n) = \beta_1 cl(C_n) + (1 - \beta_1) cl(C_n) \supseteq \beta_1 cl(C_n)$ for some small $\epsilon$. Thus, $\beta_1 cl(C_n)$ is a compact set in the interior $\text{int}(cl(C_n))$. In the proof of Lemma 4, we have shown that $\text{int}(cl(C_n)) = \text{int}(C_n)$. Thus, (iv) $\beta_1 cl(C_n)$ is a compact set in the interior $C_n$. Then, by Lemma 4, there exists $N$ such that $C_N \supseteq \beta_1 cl(C_n)$. □

**Proof of Theorem 5.** Define
\begin{equation}
\lambda_{0,1} = \frac{\lambda_{0,1} - \lambda_{\gamma}}{1 - \lambda_{\gamma}};
\lambda_{0,2} = \frac{\lambda_{\gamma}(1 - \lambda_{0,2})}{1 - \lambda_{\gamma}}.
\end{equation}
(44)

It is easy to check that $\lambda_{0,1} \geq 0$, $\lambda_{0,2} \geq 0$, $\lambda_0 = \lambda_{0,1} + \lambda_{0,2}$ and $1 - \lambda_{0,1} = \lambda_{0,2}/(\lambda_{\gamma})$. Thus, by Lemmas 2 and 3 we have
\begin{align*}
\text{Pre}_\gamma^N (\lambda_{0,1} C_0, S_{\text{max}}, D) &\supseteq \text{Pre}_\gamma^N (\lambda_{0,1} C_0, \lambda_{0,1} S_{\text{max}}, D) + \text{Pre}_\gamma^N (\lambda_{0,2} C_0, \lambda_{0,2} S_{\text{max}}, D) \\
&= \lambda_{0,1} \text{Pre}_\gamma^N (C, S_{\text{max}}, D) + \lambda_{0,2} \text{Pre}_\gamma^N (\lambda_{\gamma} C_0, S_{\text{max}}, D) \\
&\supseteq \lambda_{0,1} C + \frac{\lambda_{0,2}}{\lambda_{\gamma}} \gamma C = g(\lambda_{0,1}) C.
\end{align*}
The inclusion in last row above holds since $\gamma C$ is $N$-step $\lambda$-contractive.
