

CONVEXITY OF 2-CONVEX TRANSLATING AND EXPANDING SOLITONS TO THE MEAN CURVATURE FLOW IN \mathbb{R}^{n+1}

JUNMING XIE AND JIANGTAO YU

ABSTRACT. In this paper, inspired by the work of Spruck-Xiao [27] and based partly on a result of Derdziński [11], we prove the convexity of complete 2-convex translating and expanding solitons to the mean curvature flow in \mathbb{R}^{n+1} . More precisely, for $n \geq 3$, we show that any n -dimensional complete 2-convex translating solitons are convex, and any n -dimensional complete 2-convex self-expanders asymptotic to (strictly) mean convex cones are convex.

1. INTRODUCTION

Self-similar solutions of the mean curvature flow are special solutions for which the shapes of the evolving surfaces are essentially preserved. They play a very important role in the singularity analysis of the mean curvature flow. In particular, self-shrinkers and translating solitons often arise as possible finite time Type I and Type II singularity models, respectively (see, e.g., [19], [1, 20]). On the other hand, self-expanders are expected to model the long time behavior of the mean curvature flow or the behavior of the flow as it emerges from conical singularities (see, e.g., [13, 2, 28, 23]). In this paper, we focus on translating solitons and self-expanders with codimension one in \mathbb{R}^{n+1} and study their convexity under the 2-convex assumption.

A *translating soliton* (or a *translator* for short) to the mean curvature flow is an immersed hypersurface Σ^n in \mathbb{R}^{n+1} satisfying the equation

$$(1.1) \quad H = \langle e_{n+1}, \nu \rangle.$$

Here and in the following, H is the mean curvature, ν denotes a global unit normal vector field and e_{n+1} is a unit direction. On the other hand, an immersed hypersurface Σ^n in \mathbb{R}^{n+1} is called a *self-expander* if there is an immersion $x : \Sigma^n \rightarrow \mathbb{R}^{n+1}$ such that

$$(1.2) \quad H = \langle x, \nu \rangle.$$

For translating solitons, when $n = 1$, the unique convex solution is the grim reaper curve Γ , which is the graph of $y = \log \sec x$, $|x| < \pi/2$. For $n \geq 2$, $\Sigma = \Gamma \times \mathbb{R}^{n-1}$ are convex translating solitons, where Γ is the 1-dimensional grim reaper. There is an entire graphical, rotationally symmetrical and strictly convex translating soliton called the “bowl soliton” (see [10]) in \mathbb{R}^{n+1} ($n \geq 2$). Note that the bowl soliton has the asymptotic expansion as an entire graph $u(x) = \frac{1}{2(n-1)} |x|^2 - \log |x| + O(1)$.

There have been a lot of efforts to classify convex translating solitons. X.-J. Wang [31] proved that, for all dimensions $n \geq 1$, a complete convex translating soliton is either an entire solution or is defined in a strip region. He also showed that the only entire convex graphical translating soliton in \mathbb{R}^3 is the bowl soliton.

As for solutions over slab regions, Bourni-Langford-Tinaglia [7] proved that there exists a strictly convex translating soliton in a slab region with width greater than π in \mathbb{R}^{n+1} ($n \geq 2$). They solved the Dirichlet problem to obtain such a translating soliton. Meanwhile, Hoffman-Ilmanen-Martín-White [17] further proved the existence for all slabs of width greater than π for the case of dimension $n = 2$. Moreover, the same authors [17] are able to prove the uniqueness in this case.

Regarding the pinching estimates for translating solitons, when $n = 2$, Spruck and Xiao [27] recently proved that any immersed two-sided mean convex translating soliton in \mathbb{R}^3 is convex. Here and in the following, *mean convex* means the mean curvature $H > 0$. As an application of Spruck-Xiao's convexity theorem, Hoffman-Ilmanen-Martín-White [17] gave a full classification of the translating solitons that are complete graphs over domains in \mathbb{R}^2 . Later on, Bourni-Langford-Tinaglia [7] extended Spruck-Xiao's result by showing that a mean convex translating soliton in \mathbb{R}^{n+1} with at most two distinct principal curvatures at each point and bounded second fundamental form is convex.

More recently, Spruck and Sun [26] proved the convexity of any immersed two-sided translating soliton $\Sigma \subset \mathbb{R}^{n+1}$ ($n \geq 3$) under the assumption that Σ is uniformly 2-convex. Here, the *uniformly 2-convex* condition means that $H > 0$ and $\kappa_1 + \kappa_2 \geq \beta H$ for some constant $\beta > 0$, where $\kappa_1 \leq \kappa_2$ are the least two principal curvatures. Although κ_1 is smooth wherever $\kappa_1 < 0$, the authors were concerned that the other principal curvatures might not be differentiable if some multiplicity changes. In [26], they successfully dealt with this issue by using a special δ -approximation of $\min\{\kappa_1, \dots, \kappa_n\}$. They also needed the uniformly 2-convex condition to show that the δ -approximation $\mu^n = \mu^n(\kappa_1, \dots, \kappa_n)$ is smooth and converges to $\min\{\kappa_1, \dots, \kappa_n\}$. As pointed out in [26], their argument in applying the Omori-Yau maximum principle is delicate and utilizes the special properties of their approximation μ^n .

It turns out, by applying a result of Derdziński [11], we can actually avoid the elaborate δ -approximation arguments in [26] and work with the eigenfunctions $\kappa_1, \kappa_2, \dots, \kappa_n$ directly. Our first main result is the following.

Theorem 1.1. *Let $\Sigma^n \subset \mathbb{R}^{n+1}$, $n \geq 3$, be a complete immersed two-sided 2-convex translating soliton for the mean curvature flow. Then Σ is convex.*

Remark 1.1. Most computations in the proof of Theorem 1.1 was carried out in the Fall of 2018 after we learned the result of Spruck-Xiao [27] through the lecture of B. White at the Lehigh Geometry and Topology Conference in May 2018. In November 2020, the work of Spruck-Sun [26] was brought to our attention. We immediately noticed their concern about the differentiability of the principal curvatures and realized that we had overlooked this issue. However, as the second fundamental form is a Codazzi tensor, we can get around this potential issue by appealing to a result of Derziński [11] on the set of $\{\kappa_1 < 0\}$ (see Lemma 2.1).

For self-expanders, Smoczyk [25] proved that any properly immersed mean convex self-expanding surface $\Sigma^2 \subset \mathbb{R}^3$ that is smoothly asymptotic to a cone must be strictly convex. Partly motivated by this work, we also study the pinching estimate for higher dimensional 2-convex asymptotically conical self-expanders. Specifically, by using similar arguments as in the proof of Theorem 1.1, we prove the following result.

Theorem 1.2. *Let $\Sigma^n \subset \mathbb{R}^{n+1}$, $n \geq 3$, be a complete immersed two-sided 2-convex self-expander asymptotic to mean convex cones. Then Σ^n is convex.*

Remark 1.2. By essentially the same argument, we can also prove a similar result for the self-shrinking case. Namely, we are able to prove that any complete immersed two-sided 2-convex self-shrinker asymptotic to mean convex cones must be convex. See Theorem 4.1.

Remark 1.3. Actually, by the assumption of 2-convexity, the asymptotic cone must be a (weakly) convex cone (see the proof of Theorem 1.2 in section 4). However, we need the assumption of the asymptotic cone being mean convex to ensure that the asymptotic cone has at least one positive principal curvature.

We also note that it is natural to assume being asymptotically conical for self-expanders. On one hand, a lot of known examples of self-expanders are asymptotically conical (see, e.g., [13], [22, 12], [2, 16]). In particular, the mean curvature flow associated to the asymptotically conical self-expander flows out of the asymptotic cone. On the other hand, in recent years, some advances in self-expanders were obtained under the assumption of being asymptotically conical. For example, regarding the uniqueness of self-expanders, Fong-McGrath [14] proved that mean convex self-expanders which are asymptotic to $O(n)$ -invariant cones are rotationally symmetric. Ding [12] has studied the relationship between minimal cones and self-expanders. More recently, Bernstein and Wang [3, 4] studied the space of asymptotically conical self-expanders of mean curvature flow, in particular compactness in the locally smooth topology for certain natural families of asymptotically conical self-expanding solutions of mean curvature flow.

Acknowledgements. Both authors are very grateful to their Ph.D. advisor Professor Huai-Dong Cao for suggesting this project in Summer 2018 and for his invaluable suggestions, constant support and encouragement. The first author would also like to thank Professor Lu Wang for helpful discussions, and Professor Knut Smoczyk for answering questions related to his paper [25].

2. PRELIMINARIES

In this section, we fix the notations for the rest of the paper and collect several results that will be used later in the proof of the main theorems.

2.1. Codazzi tensors. A symmetric $(0, 2)$ tensor T on a Riemannian manifold is said to be a *Codazzi tensor* if it satisfies the *Codazzi equation*

$$(\nabla_X T)(Y, Z) = (\nabla_Y T)(X, Z)$$

for any tangent vector fields X, Y , and Z . Now, we recall a very useful result of Derdziński [11] (valid for any Codazzi tensor) that we shall need in the proof of our main theorems. Define the integer-valued function E_A for the second fundamental form A on Σ by

$$E_A(p) = \text{the number of distinct eigenvalues of } A(p).$$

Let $\Sigma_A = \{p \in \Sigma : E_A \text{ is constant in a neighborhood of } p\}$, then Σ_A is open and dense in Σ (see [11]). We now set

$$\Sigma^- = \{p \in \Sigma : \text{the least eigenvalue of } A \text{ is negative at } p\}$$

and define

$$\Sigma_A^- := \Sigma^- \cap \Sigma_A.$$

It is clear that Σ_A^- is an open dense subset of Σ^- . Notice also the 2-convexity condition of $\kappa_1 + \kappa_2 > 0$ ensures that κ_1 is smooth in the open set Σ^- .

Lemma 2.1.¹ (Derdziński [11]) *Given any Codazzi tensor A on a Riemannian manifold Σ^n , we have, on each connected component Ω of Σ_A^- ,*

- (1) *The eigendistributions of A are integrable and their leaves are totally umbilic submanifolds of Σ^- ,*
- (2) *Eigenspaces of A form mutually orthogonal differentiable distributions.*

Let E_1, \dots, E_m be the local eigendistributions of A around any point $p \in \Omega$. Let the dimension of the E_l be d_l , $l = 1, \dots, m$. Then there exist local orthonormal eigenvector fields $\{\tau_i\}_{i=1}^n$ around p such that

$$\{\tau_1, \dots, \tau_{d_1}\} \in E_1, \{\tau_{d_1+1}, \dots, \tau_{d_1+d_2}\} \in E_2, \dots, \{\tau_{d_1+\dots+d_{m-1}+1}, \dots, \tau_n\} \in E_m.$$

Define

$$\kappa_i = A(\tau_i, \tau_i).$$

Then, with suitable labeling, locally we can have $\kappa_1 \leq \kappa_2 \leq \dots \leq \kappa_n$.

From now on, we shall call the above special local (tangent) frame $\{\tau_i\}_{i=1}^n$ the *adapted moving frame* around point p .

Lemma 2.2. *On each connected component Ω of Σ_A^- , let $\{\tau_j\}_{j=1}^n$ be the adapted moving frame around a point p in Ω . Then, for any eigenvalue κ_i of multiplicity one and at the point p , we have*

$$(2.1) \quad \nabla \kappa_i = (\nabla A)(\tau_i, \tau_i),$$

$$(2.2) \quad \Delta \kappa_i = (\Delta A)(\tau_i, \tau_i) - 2 \sum_{l \neq i} \frac{|(\nabla A)(\tau_l, \tau_i)|^2}{\kappa_l - \kappa_i}.$$

Proof. We shall use the convention that ∇_j means ∇_{τ_j} . With the adapted moving frame $\{\tau_j\}_{j=1}^n$, we have

$$(2.3) \quad \langle \tau_i, \tau_i \rangle = 1 \implies \langle \nabla_j \tau_i, \tau_i \rangle = 0 \quad \forall j = 1, \dots, n.$$

Then, the first conclusion (2.1) follows easily: for any local vector field τ around p ,

$$(2.4) \quad \nabla_\tau \kappa_i = \nabla_\tau (A(\tau_i, \tau_i)) = (\nabla_\tau A)(\tau_i, \tau_i) + 2A(\nabla_\tau \tau_i, \tau_i) = (\nabla_\tau A)(\tau_i, \tau_i).$$

Next, for any $l \neq i$, we have

$$(2.5) \quad \langle \tau_l, \tau_i \rangle = 0 \implies \langle \nabla_j \tau_l, \tau_i \rangle + \langle \tau_l, \nabla_j \tau_i \rangle = 0 \quad \forall j.$$

We can differentiate (2.3) once more to get

$$(2.6) \quad \langle \nabla_j \tau_i, \tau_i \rangle = 0 \implies \langle \nabla_j \nabla_j \tau_i, \tau_i \rangle + \langle \nabla_j \tau_i, \nabla_j \tau_i \rangle = 0.$$

From $A(\tau_l, \tau_i) = 0$ for any $l \neq i$, we get $\nabla_j (A(\tau_l, \tau_i)) = 0$, which implies that

$$(2.7) \quad \begin{aligned} (\nabla_j A)(\tau_l, \tau_i) &= -A(\nabla_j \tau_l, \tau_i) - A(\tau_l, \nabla_j \tau_i) \\ &= -\kappa_i \langle \nabla_j \tau_l, \tau_i \rangle - \kappa_l \langle \tau_l, \nabla_j \tau_i \rangle \\ &= -(\kappa_l - \kappa_i) \langle \tau_l, \nabla_j \tau_i \rangle, \end{aligned}$$

¹In early April 2021, we became aware of the work of Singley [24] and found that his work suits our needs more directly.

where we have used (2.5) in the last equality.

Let $\xi_i = \tau_i(p)$ and extend ξ_i by parallel translation along radial geodesics emanating from p . Then, at p , we have

$$\begin{aligned}
 \Delta \kappa_i &= \sum_j \nabla_{\xi_j} \nabla_{\xi_j} (A(\tau_i, \tau_i)) \\
 &= \sum_j \nabla_{\xi_j} ((\nabla_{\xi_j} A)(\tau_i, \tau_i)) \\
 (2.8) \quad &= (\Delta A)(\tau_i, \tau_i) + 2 \sum_j (\nabla_{\xi_j} A)(\nabla_{\xi_j} \tau_i, \tau_i) \\
 &= (\Delta A)(\tau_i, \tau_i) + 2 \sum_j (\nabla_j A)(\nabla_j \tau_i, \tau_i).
 \end{aligned}$$

Here, in the second equality, we have used (2.3). Now, it remains to compute and analyze the term $(\nabla_j A)(\nabla_j \tau_i, \tau_i)$. By using $A(\nabla_j \tau_i, \tau_i) = 0$, we obtain

$$(2.9) \quad (\nabla_j A)(\nabla_j \tau_i, \tau_i) + A(\nabla_j \nabla_j \tau_i, \tau_i) + A(\nabla_j \tau_i, \nabla_j \tau_i) = 0.$$

For the second term in (2.9), as $\nabla_j \tau_i = \sum_{l \neq i} \langle \nabla_j \tau_i, \tau_l \rangle \tau_l$, it follows from (2.6) that

$$A(\nabla_j \nabla_j \tau_i, \tau_i) = -\kappa_i \langle \nabla_j \tau_i, \nabla_j \tau_i \rangle = -\sum_{l \neq i} \kappa_l (\langle \nabla_j \tau_i, \tau_l \rangle)^2.$$

For the last term in (2.9), we have

$$A(\nabla_j \tau_i, \nabla_j \tau_i) = \sum_{l \neq i} \kappa_l (\langle \nabla_j \tau_i, \tau_l \rangle)^2.$$

Hence, by using (2.7), we get

$$(2.10) \quad (\nabla_j A)(\nabla_j \tau_i, \tau_i) = -\sum_{l \neq i} (\kappa_l - \kappa_i) (\langle \nabla_j \tau_i, \tau_l \rangle)^2 = -\sum_{l \neq i} \frac{|(\nabla_j A)(\tau_l, \tau_i)|^2}{\kappa_l - \kappa_i}.$$

The second conclusion (2.2) in Lemma 2.3 now follows from (2.8) and (2.10). \square

2.2. Translating solitons. Recall the following well-known basic properties of translating solitons for the mean curvature flow (see, e.g., [21, 29, 26]).

Lemma 2.3. *Let $f : \Sigma^n \rightarrow \mathbb{R}^{n+1}$ be a complete immersed two-sided translating soliton satisfying Eq. (1.1). Let $A = (h_{ij})$ be the second fundamental form, $\Delta^f := \Delta^\Sigma + \langle \nabla \cdot, e_{n+1} \rangle$ be the drift Laplacian on Σ . Then*

- (1) $\Delta^f H + |A|^2 H = 0$,
- (2) $\Delta^f A + |A|^2 A = 0$,
- (3) $\Delta^f (|A|^2) + 2|A|^4 - 2|\nabla A|^2 = 0$.

In the proof of Theorem 1.1, we shall need the following version of the Omori-Yau maximal principle (see [18]).

Lemma 2.4. (Omori-Yau Maximal Principle) *Let (M, g) be a complete Riemannian manifold with Ricci curvature bounded from below. Let $f : M \rightarrow \mathbb{R}$ be a smooth function that is bounded below. Then there is a sequence p_k in M such that*

$$f(p_k) \rightarrow \inf_M f, \quad \nabla f(p_k) \rightarrow 0, \quad \liminf \Delta f(p_k) \geq 0.$$

Moreover, the theorem remains true if we replace the assumption that f is smooth by the assumption that f is smooth on $\{f < \alpha\}$ for some $\alpha > \inf_M f$.

Remark 2.1. Observe that, by the translator equation (1.1), $H \leq 1$. This implies that if $\Sigma^n \subset \mathbb{R}^{n+1}$ is 2-convex then $|A|^2 \leq nH^2 \leq n$. On the other hand, by the Gauss equation, $R_{ij} = Hh_{ij} - h_{ik}h_{kj}$. Thus, for any 2-convex translator Σ , its Ricci curvature is automatically bounded from below so Lemma 2.4 applies.

2.3. Self-expanders. For self-expanders of the mean curvature flow, we have the following well-known basic properties (see, e.g., [12]).

Lemma 2.5. *Let $x : \Sigma^n \rightarrow \mathbb{R}^{n+1}$ be a complete immersed two-side self-expander satisfying Eq. (1.2). Let $A = (h_{ij})$ be the second fundamental form, $\mathcal{L} := \Delta^\Sigma + \langle \nabla \cdot, x \rangle$ be the drift Laplacian on Σ . Then*

- (1) $\mathcal{L}H + H(1 + |A|^2) = 0$,
- (2) $\mathcal{L}A + A(1 + |A|^2) = 0$,
- (3) $\mathcal{L}(|A|^2) + 2|A|^2(1 + |A|^2) - 2|\nabla A|^2 = 0$.

Finally, we recall the definition of asymptotically conical self-expander and some of its geometric properties. We say that a cone $\mathcal{C} \subset \mathbb{R}^{n+1}$ is a *regular cone* with vertex at the origin, if $\mathcal{C} = \{\rho\Gamma^{n-1}, 0 \leq \rho < \infty\}$, where Γ^{n-1} is a smooth connected closed embedded submanifold of the unit sphere \mathbb{S}^n . Note that the induced metric on \mathcal{C} satisfies $g_{\mathcal{C}} = dr \otimes dr + r^2 g_\Gamma$, for r the radial variable.

A self-expander $\Sigma^n \subset \mathbb{R}^{n+1}$ is *asymptotically conical* if it is smoothly asymptotic to a regular cone \mathcal{C} such that

$$\mathcal{C} = \lim_{t \rightarrow 0^+} \sqrt{t}\Sigma,$$

in the sense that, for any $R > 0$ and $k \in \mathbb{N}$, $\sqrt{t}\Sigma \cap (\bar{B}_R \setminus B_{1/R})$ converges to $\mathcal{C} \cap (\bar{B}_R \setminus B_{1/R})$ in the C^k topology, as $t \rightarrow 0^+$ (see, e.g., [30]).

Note that, outside a compact set, the asymptotically conical self-expander can be parametrized by a graph over the asymptotic cone \mathcal{C} . Namely, we have

Lemma 2.6. (Ding [12]) *Let $\Sigma^n \subset \mathbb{R}^{n+1}$ be an asymptotically conical self-expander with the asymptotic cone \mathcal{C} . Then for $R > 0$ sufficiently large, there is a function $u \in C^\infty(\mathcal{C} \setminus B_R(0))$ so that*

$$\text{graph } u := \{\tilde{p} + u(\tilde{p})\nu_{\mathcal{C}}(\tilde{p}) \mid \tilde{p} \in \mathcal{C} \setminus B_R(0)\} \subset \Sigma.$$

Moreover, the function u satisfies

$$(2.11) \quad |\nabla_{\mathcal{C}}^i u(\tilde{p})| = O(r^{-i-1}), \quad \text{for } i = 0, 1,$$

as $r = |\tilde{p}| \rightarrow \infty$. Here and in the following, big O means $O(r^{-i-1}) \leq cr^{-i-1}$ for some constant c .

Remark 2.2. Actually, by the self-expander equation and an induction argument (see the proof of Lemma A.1 in [9]), the estimate (2.11) also holds for $i \geq 2$.

Let $\tilde{p} \in \mathcal{C} \setminus B_R(0)$ for $R > 0$ sufficiently large. Then there is a domain U including 0 in \mathbb{R}^n and a local parametrization of \mathcal{C} in a neighborhood of \tilde{p} , $\tilde{F} : U \rightarrow \mathcal{C}$ such that

$$\tilde{F}(0) = \tilde{p}, \quad \langle \partial_i \tilde{F}(0), \partial_j \tilde{F}(0) \rangle = \tilde{\delta}_{ij},$$

and

$$\partial_{ij}^2 \tilde{F}(0) = \tilde{h}_{ij} \nu_{\mathcal{C}}(\tilde{p})$$

with

$$\tilde{h}_{ij} = \langle \partial_{ij}^2 \tilde{F}, \nu_{\mathcal{C}} \rangle, \quad \tilde{h}_{ij}(0) = 0 \text{ if } i \neq j.$$

By Lemma 2.6, in a neighborhood of $p = \tilde{p} + u(\tilde{p})\nu_{\mathcal{C}}(\tilde{p})$, we can choose a local parametrization of Σ , $F : U \rightarrow \Sigma$ such that

$$F(x) = \tilde{F}(x) + u(\tilde{F}(x))\nu_{\mathcal{C}}(\tilde{F}(x)),$$

for $x \in U$. Then we have

Lemma 2.7. (Ding [12]) *Let $F : U \rightarrow \Sigma$ be the parametrization as above such that $F(x) = \tilde{F}(x) + u(\tilde{F}(x))\nu_{\mathcal{C}}(\tilde{F}(x))$, for $x \in U$. Then at the point $x = 0$, we have*

$$h_{ij} = c(x) \cdot \left\{ (\tilde{h}_{ij} - \tilde{h}_{ii}\tilde{h}_{jj}\tilde{\delta}^{ij}u + \partial_{ij}^2u) \prod_k (1 - \tilde{h}_{kk}u) + Q_{1ij}(x, u, \nabla_{\mathcal{C}}u) \right\},$$

where $|Q_{1ij}(x, u, \nabla_{\mathcal{C}}u)| \leq c|\tilde{p}|^{-1}|\nabla_{\mathcal{C}}u|^2 + c|\tilde{p}|^{-2}|u||\nabla_{\mathcal{C}}u| = O(r^{-5})$ and $c(x) = O(1)$, as $r \rightarrow \infty$. Also, we have

$$g^{ij} = \tilde{\delta}^{ij}(1 + 2\tilde{h}_{ii}u) + Q_{2ij}(x, u, \nabla_{\mathcal{C}}u),$$

where $|Q_{2ij}(x, u, \nabla_{\mathcal{C}}u)| \leq c|\tilde{p}|^{-2}u^2 + c|\nabla_{\mathcal{C}}u|^2 = O(r^{-4})$, as $r \rightarrow \infty$.

Remark 2.3. For the analog results of Lemma 2.6 and Lemma 2.7 for asymptotically conical self-shrinkers, see [30] by L. Wang and [8, 9] by Chodosh et al. Note that in [8, 9], the authors only stated their improved conical estimates for self-shrinkers (see Lemma 2.7 in [8] and Lemma A.2 in [9]). However, as equation (2.1) in [8] also holds for self-expanders, their arguments can imply the same improved conical estimates for self-expanders.

3. PROOF OF THEOREM 1.1

In this section, we focus on the translator case and prove Theorem 1.1 as stated in the introduction. Let Σ be given as in Theorem 1.1. Recall that, according to the ordering of the eigenvalues in Section 2, κ_1 is the least eigenvalue. By the 2-convexity assumption, we have $\kappa_1 + \kappa_2 > 0$, and the function κ_1/H is bounded on Σ by

$$\frac{-1}{n-2} \leq \frac{\kappa_1}{H} < 1.$$

Suppose Σ^- is not empty, then we have

$$\inf_{\Sigma} \left(\frac{\kappa_1}{H} \right) = \epsilon_0 < 0.$$

Following Spruck and Xiao [27], we define

$$\varphi(r) := \begin{cases} -r^4 e^{-1/r^2} & \text{if } r < 0 \\ 0 & \text{if } r \geq 0. \end{cases}$$

It is easy to check that we have $\dot{\varphi} > 0$ and $\ddot{\varphi} < 0$ for $r < 0$. Moreover, $\dot{\varphi}$ and $\ddot{\varphi}$ are both bounded away from 0 on $[-r_2, -r_1]$, for any $r_2 > r_1 > 0$. Now let

$$\varphi := \varphi(\kappa_1/H),$$

and then φ is continuous on Σ and smooth on Σ^- .

Define the linear elliptic operator L by

$$L\varphi = \Delta^{\Sigma}\varphi + \langle \nabla\varphi, e_{n+1} \rangle + 2 \left\langle \nabla\varphi, \frac{\nabla H}{H} \right\rangle.$$

Lemma 3.1. *On each connected component of Σ_A^- , we have*

$$L\varphi = \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 - 2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} \leq 0.$$

Proof. First of all, by direct computations, we have

$$\begin{aligned} & \Delta^\Sigma \varphi \left(\frac{\kappa_1}{H} \right) \\ (3.1) \quad &= \dot{\varphi} \Delta^\Sigma \left(\frac{\kappa_1}{H} \right) + \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 \\ &= \frac{\dot{\varphi}}{H^2} (H \Delta^\Sigma \kappa_1 - \kappa_1 \Delta^\Sigma H) - 2\dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), \frac{\nabla H}{H} \right\rangle + \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2. \end{aligned}$$

On the other hand, by Lemma 2.3 and Lemma 2.2,

$$\begin{aligned} H \Delta^\Sigma \kappa_1 - \kappa_1 \Delta^\Sigma H &= H \left(\Delta^\Sigma h_{11} - 2 \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1} \right) - \kappa_1 \Delta^\Sigma H \\ (3.2) \quad &= -\langle H \nabla \kappa_1 - \kappa_1 \nabla H, e_{n+1} \rangle - 2H \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1} \\ &= -H^2 \left\langle \nabla \left(\frac{\kappa_1}{H} \right), e_{n+1} \right\rangle - 2H \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1}. \end{aligned}$$

Combining (3.1) and (3.2), we get

$$\Delta^\Sigma \varphi = \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 - 2\dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), \frac{\nabla H}{H} \right\rangle - \dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), e_{n+1} \right\rangle - 2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)}.$$

Finally, the inequality in the lemma follows from the facts that $\dot{\varphi} > 0$, $\ddot{\varphi} < 0$ and $\kappa_l > \kappa_1$ for any $l \neq 1$. \square

Now we are ready to prove Theorem 1.1.

Proof of Theorem 1.1. We argue by contradiction. Suppose the theorem is false. Then Σ^- is non-empty and we have

$$\xi := \inf_{\Sigma} \varphi \left(\frac{\kappa_1}{H} \right) < 0.$$

Case 1: interior infimum. If the infimum ξ is attained at some point $p_0 \in \Sigma$, then p_0 must be in Σ^- . Since Σ_A^- is open and dense in Σ^- , by Lemma 3.1, we have $L\varphi(p) \leq 0$ for any point $p \in \Sigma^-$. Hence, it follows from the strong maximum principle that $\varphi = \varphi(\kappa_1/H)$ is a constant function on Σ^- . Then, on each connected component of Σ_A^- , we have

$$(3.3) \quad \kappa_1/H \equiv \varepsilon_0 := \varphi^{-1}(\xi) < 0,$$

$$(3.4) \quad \kappa_n/H \geq \dots \geq \kappa_2/H \geq -\kappa_1/H = -\varepsilon_0 > 0,$$

$$(3.5) \quad \nabla \left(\frac{\kappa_1}{H} \right) = \frac{H \nabla \kappa_1 - \kappa_1 \nabla H}{H^2} = \frac{\nabla \kappa_1 - \varepsilon_0 \nabla H}{H} = 0.$$

By Lemma 3.1, we get

$$(3.6) \quad \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} = 0$$

on each connected component of Σ_A^- as well.

From (3.6), we have $\nabla h_{l1} = 0$ for $l \neq 1$. In particular, it follows from the Codazzi equation that $\nabla_l \kappa_1 = \nabla_l h_{11} = 0$ and $\nabla_1 \kappa_l = \nabla_1 h_{ll} = 0$ for all $l \neq 1$. Combining this with (3.5), we get

$$\nabla_1 \kappa_1 = \frac{\epsilon_0}{1 - \epsilon_0} \nabla_1 (h_{22} + \cdots + h_{nn}) = 0.$$

Thus $\nabla \kappa_1 = 0$, which implies $\nabla H = 0$ by (3.5), i.e., H is constant (on each connected component of Σ_A^-).

However, by Lemma 2.3, $\Delta^f H + |A|^2 H = 0$ hence $H = 0$. This is a contradiction to the 2-convexity assumption. Therefore, the infimum ξ cannot be attained on Σ .

Case 2: infinity infimum. Since $\xi := \inf_{\Sigma} \varphi \left(\frac{\kappa_1}{H} \right) < 0$, we may take $\alpha = 0$ in Lemma 2.4. Then φ is smooth on $\{\varphi < \alpha\} = \Sigma^-$, and it follows from the Omori-Yau maximum principle (Lemma 2.4 and Remark 2.1) that there exists a sequence $\{p_k\}$ of points in Σ such that

$$\varphi(p_k) \rightarrow \xi, \quad |\nabla \varphi|(p_k) \rightarrow 0, \quad \Delta^{\Sigma} \varphi(p_k) \rightarrow \delta \geq 0.$$

Since $\varphi(p_k) \rightarrow \xi < 0$, without loss of generality, we may assume all p_k 's are in Σ^- . In view of the fact that Σ_A^- is open and dense in Σ^- , for each k , we can pick some point $q_k \in \Sigma_A^-$ close to p_k (after passing to the ‘‘diagonal’’ subsequence) such that

$$(3.7) \quad \varphi(q_k) \rightarrow \xi, \quad |\nabla \varphi|(q_k) \equiv \dot{\varphi} |\nabla(\kappa_1/H)|(q_k) \rightarrow 0, \quad \Delta^{\Sigma} \varphi(q_k) \rightarrow \delta \geq 0.$$

For the rest of the proof, the computations will be carried out around such $q_k \in \Sigma_A^-$, and all the limits are taken at q_k as $k \rightarrow \infty$.

By (3.7) and Lemma 3.1, at q_k , we have

$$(3.8) \quad \begin{aligned} \Delta^{\Sigma} \varphi &= \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 - 2\dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), \frac{\nabla H}{H} \right\rangle - \dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), e_{n+1} \right\rangle \\ &\quad - 2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} \rightarrow \delta \geq 0, \text{ as } k \rightarrow \infty. \end{aligned}$$

Since $\dot{\varphi}$ is positive and bounded away from 0 as $k \rightarrow \infty$, it follows from (3.7) that $\nabla(\kappa_1/H)(q_k) \rightarrow 0$. We also note, by the translator equation (1.1), that

$$(3.9) \quad \nabla_i H = -h_{ij} \langle \tau_j, e_{n+1} \rangle,$$

which implies $|\nabla H|^2 \leq |A|^2 \leq nH^2$. Hence $|\nabla H|/H$ is bounded. Together with the fact that $|\dot{\varphi}|$ is also bounded away from 0 as $k \rightarrow \infty$, it follows that the first three terms on the RSH of (3.8) all have limits 0 as $k \rightarrow \infty$.

Therefore, since $\Delta^{\Sigma} \varphi(q_k) \rightarrow \delta \geq 0$ while $-2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} \leq 0$, we conclude that

$$\sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} = \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H^2} \frac{H}{(\kappa_l - \kappa_1)} \rightarrow 0.$$

Note that $\frac{H}{\kappa_l - \kappa_1} \geq \frac{H}{H+H} = \frac{1}{2}$ for $l \neq 1$, thus

$$(3.10) \quad \frac{|\nabla h_{ll}|^2}{H^2} \rightarrow 0.$$

Combining (3.10) with the Codazzi equation, we get

$$(3.11) \quad \frac{\nabla_l h_{11}}{H} = \frac{\nabla_l \kappa_1}{H} \rightarrow 0, \quad \forall l \neq 1,$$

$$(3.12) \quad \frac{\nabla_1 h_{ll}}{H} = \frac{\nabla_1 \kappa_l}{H} \rightarrow 0, \quad \forall l \neq 1.$$

In particular, since

$$(3.13) \quad \nabla \left(\frac{\kappa_1}{H} \right) = \frac{\nabla \kappa_1}{H} - \frac{\kappa_1 \nabla H}{H^2} \rightarrow 0,$$

we have

$$(3.14) \quad \begin{aligned} \nabla_1 \left(\frac{\kappa_1}{H} \right) &= \frac{\nabla_1 \kappa_1}{H} - \frac{\kappa_1 \nabla_1 H}{H^2} \\ &= \left(\frac{\nabla_1 \kappa_1}{H} - \frac{\kappa_1 \nabla_1 \kappa_1}{H^2} \right) - \frac{\kappa_1 \nabla_1 (h_{22} + \cdots + h_{nn})}{H^2} \rightarrow 0. \end{aligned}$$

By using (3.12) and the fact that $\kappa_1/H \rightarrow \epsilon_0 < 0$, it follows that the second term in the second identity of (3.14) converges to 0 as $k \rightarrow \infty$. So

$$\frac{\nabla_1 \kappa_1}{H} - \frac{\kappa_1 \nabla_1 \kappa_1}{H^2} = \frac{\nabla_1 \kappa_1}{H} \left(1 - \frac{\kappa_1}{H} \right) \rightarrow 0,$$

hence

$$(3.15) \quad \frac{\nabla_1 \kappa_1}{H} \rightarrow 0.$$

Combining (3.11) and (3.15), we obtain

$$\frac{\nabla \kappa_1}{H} \rightarrow 0.$$

Thus, by (3.13),

$$\frac{\nabla H}{H} \rightarrow 0.$$

Now, using (3.9), for any l , we obtain

$$(3.16) \quad \frac{-\kappa_l \langle \tau_l, e_{n+1} \rangle}{H} = \frac{\nabla_l H}{H} \rightarrow 0.$$

We also observe that

$$(3.17) \quad \lim_{k \rightarrow \infty} \frac{\kappa_n}{H}(q_k) \geq \cdots \geq \lim_{k \rightarrow \infty} \frac{\kappa_2}{H}(q_k) \geq - \lim_{k \rightarrow \infty} \frac{\kappa_1}{H}(q_k) = -\epsilon_0 > 0.$$

Therefore, by (3.16) and (3.17), we conclude that the unit normal sequence $\{N(q_k)\}$ converges to e_{n+1} , and hence $H(q_k) \rightarrow 1$ as $k \rightarrow \infty$.

Now, as in Spruck-Xiao [27], we let $\Gamma_k = \Sigma - q_k$ be the hypersurface obtained from Σ by translating q_k to the origin. Since Σ has bounded second fundamental form, so does Γ_k . By the compactness theorem for translator (see, e.g., [18]), we can choose a subsequence, which we still denote by $\{\Gamma_k\}_{k=1}^\infty$, such that $\{\Gamma_k\}$ converges smoothly to some limit hypersurface Γ_∞ . Then Γ_∞ is a 2-convex translating soliton and satisfies $H(0) = 1$. Moreover, the corresponding function φ for Γ_∞ attains its minimum on Γ_∞ at the origin, which is impossible by the conclusion in **Case 1**.

Therefore Σ must be convex. This completes the proof of Theorem 1.1. \square

4. PROOF OF THEOREM 1.2

In this section, we consider the self-expander case and prove the convexity of 2-convex asymptotically conical self-expanders with mean convex asymptotic cones. Let Σ be given as in Theorem 1.2 and suppose Σ^- is not empty. By the 2-convexity assumption, we have

$$\inf_{\Sigma} \left(\frac{\kappa_1}{H} \right) = \epsilon_0 < 0.$$

Following Spruck and Xiao [27], we define $\varphi(r)$ as in section 3 and let

$$\varphi := \varphi(\kappa_1/H),$$

and then φ is continuous on Σ and smooth on Σ^- .

Define another linear elliptic operator \bar{L} by

$$\bar{L}\varphi = \Delta^{\Sigma}\varphi + \langle \nabla\varphi, x \rangle + 2 \left\langle \nabla\varphi, \frac{\nabla H}{H} \right\rangle.$$

Lemma 4.1. *On each connected component of Σ_A^- , we have*

$$\bar{L}\varphi = \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 - 2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)} \leq 0.$$

Proof. First of all, by direct computations, we have

$$\begin{aligned} & \Delta^{\Sigma}\varphi \left(\frac{\kappa_1}{H} \right) \\ (4.1) \quad &= \dot{\varphi} \Delta^{\Sigma} \left(\frac{\kappa_1}{H} \right) + \ddot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 \\ &= \frac{\dot{\varphi}}{H^2} (H \Delta^{\Sigma} \kappa_1 - \kappa_1 \Delta^{\Sigma} H) - 2\dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), \frac{\nabla H}{H} \right\rangle + \ddot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2. \end{aligned}$$

On the other hand, by Lemma 2.5 and Lemma 2.2,

$$\begin{aligned} H \Delta^{\Sigma} \kappa_1 - \kappa_1 \Delta^{\Sigma} H &= H \left(\Delta^{\Sigma} h_{11} - 2 \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1} \right) - \kappa_1 \Delta^{\Sigma} H \\ &= H (-\langle \nabla h_{11}, x \rangle - h_{11}(1 + |A|^2)) - 2H \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1} \\ (4.2) \quad &+ \kappa_1 (\langle \nabla H, x \rangle + H(1 + |A|^2)) \\ &= -\langle H \nabla \kappa_1 - \kappa_1 \nabla H, x \rangle - 2H \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1} \\ &= -H^2 \left\langle \nabla \left(\frac{\kappa_1}{H} \right), x \right\rangle - 2H \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{\kappa_l - \kappa_1}. \end{aligned}$$

Combining (4.1) and (4.2), we get

$$\Delta^{\Sigma}\varphi = \dot{\varphi} \left| \nabla \left(\frac{\kappa_1}{H} \right) \right|^2 - 2\dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), \frac{\nabla H}{H} \right\rangle - \dot{\varphi} \left\langle \nabla \left(\frac{\kappa_1}{H} \right), x \right\rangle - 2\dot{\varphi} \sum_{l \neq 1} \frac{|\nabla h_{l1}|^2}{H(\kappa_l - \kappa_1)}.$$

Finally, the inequality in the lemma follows from the facts that $\dot{\varphi} > 0$, $\ddot{\varphi} < 0$ and $\kappa_l > \kappa_1$ for any $l \neq 1$. \square

Remark 4.1. By the same computations, the above lemma also holds similarly for self-shrinkers.

Next, using Lemma 2.6 and Lemma 2.7, we investigate the decay rate of the principal curvatures of asymptotically conical self-expanders.

Lemma 4.2. *Let $\Sigma^n \subset \mathbb{R}^{n+1}$ be an asymptotically conical self-expander with the asymptotic cone \mathcal{C} . For $1 \leq i \leq n$, denote κ_i as the principal curvatures of Σ and $\tilde{\kappa}_i$ as the corresponding principal curvatures of \mathcal{C} . Then, as $r \rightarrow \infty$, we have*

$$\kappa_i = O(r^{-3}), \text{ if } \tilde{\kappa}_i = 0; \quad \kappa_i = O(r^{-1}), \text{ if } \tilde{\kappa}_i \neq 0; \quad H = O(r^{-1}).$$

Proof. In this proof, without loss of generality, we may assume $i = 1$ is the direction of radial r . First of all, we recall that for a cone \mathcal{C} , if $j \geq 2$, we have

$$\tilde{g}_{11} = 1, \quad \tilde{g}_{1j} = 0, \quad \text{and} \quad \tilde{g}^{11} = 1, \quad \tilde{g}^{1j} = 0.$$

Moreover, if $i, j \geq 2$, we have

$$\tilde{g}_{ij} = O(r^2), \quad \text{and} \quad \tilde{g}^{ij} = O(r^{-2}), \quad \text{as } r \rightarrow \infty.$$

For the second fundamental form and the mean curvature of \mathcal{C} , as $r \rightarrow \infty$, we have

$$\tilde{h}_{1j} = 0 \text{ for } j \geq 1, \quad \tilde{h}_{ij} = O(r) \text{ for } i, j \geq 2, \quad \text{and} \quad \tilde{H} = O(r^{-1}).$$

Thus at the point $p \in \Sigma$, by Lemma 2.6 and Lemma 2.7, we get

$$\begin{aligned} h_{1j} &= O(1) \cdot \left\{ (\tilde{h}_{1j} - \tilde{h}_{11}\tilde{h}_{jj}\tilde{\delta}^{1j}u + \partial_{1j}^2 u) \prod_k (1 - \tilde{h}_{kk}u) + Q_{1ij}(x, u, \nabla_{\mathcal{C}}u) \right\} \\ &= O(r^{-3}) \cdot O(1) + O(r^{-5}) \\ &= O(r^{-3}), \end{aligned}$$

and, for $i, j \geq 2$,

$$\begin{aligned} h_{ij} &= O(1) \cdot \left\{ (\tilde{h}_{ij} - \tilde{h}_{ii}\tilde{h}_{jj}\tilde{\delta}^{ij}u + \partial_{ij}^2 u) \prod_k (1 - \tilde{h}_{kk}u) + Q_{1ij}(x, u, \nabla_{\mathcal{C}}u) \right\} \\ &= (\tilde{h}_{ij} + O(r^{-1}) + O(r^{-3})) \cdot O(1) + O(r^{-5}) \\ &= \tilde{h}_{ij} \cdot O(1) + O(r^{-1}). \end{aligned}$$

On the other hand, we have

$$\begin{aligned} g^{11} &= \tilde{\delta}^{11}(1 + 2\tilde{h}_{11}u) + Q_{2ij}(x, u, \nabla_{\mathcal{C}}u) \\ &= 1 + O(r^{-4}) \\ &= O(1), \end{aligned}$$

and, for $j \geq 2$,

$$g^{1j} = \tilde{\delta}^{1j}(1 + 2\tilde{h}_{11}u) + Q_{2ij}(x, u, \nabla_{\mathcal{C}}u) = O(r^{-4}).$$

Furthermore, for $i, j \geq 2$, we obtain

$$\begin{aligned} g^{ij} &= \tilde{\delta}^{ij}(1 + 2\tilde{h}_{ii}u) + Q_{2ij}(x, u, \nabla_{\mathcal{C}}u) \\ &= O(r^{-2}) \cdot O(1) + O(r^{-4}) \\ &= O(r^{-2}). \end{aligned}$$

Therefore, at the point $p \in \Sigma$, we have

$$(4.3) \quad h_j^1 = \sum_k g^{1k} h_{kj} = g^{11} h_{1j} + \sum_{k \geq 2} g^{1k} h_{kj} = O(r^{-3}),$$

and, for $i, j \geq 2$,

$$(4.4) \quad h_j^i = \sum_k g^{ik} h_{kj} = \sum_k O(r^{-2}) \cdot (\tilde{h}_{kj} + O(r^{-1})) = O(r^{-2}) \cdot \tilde{h}_{jj} + O(r^{-3}).$$

Finally, Lemma 4.2 follows from (4.3) and (4.4). \square

Now we are ready to prove Theorem 1.2.

Proof of Theorem 1.2. Again, we argue by contradiction and assume the theorem is false. Then Σ^- is non-empty, and we have

$$\xi := \inf_{\Sigma} \varphi \left(\frac{\kappa_1}{H} \right) < 0.$$

Case 1: interior infimum. If the infimum ξ is attained at some point $p_0 \in \Sigma$, then p_0 must be in Σ^- . By Lemma 4.1 and the same argument in the translator case in section 3, we conclude that the mean curvature H is constant on each connected component of $\Sigma_{\mathcal{A}}^-$. However, by Lemma 2.5, $\Delta^{\Sigma} H + \langle \nabla H, x \rangle = -H(1 + |A|^2)$ hence $H = 0$, which is a contradiction to the 2-convexity assumption. Therefore, the infimum ξ cannot be attained on Σ .

Case 2: infinity infimum. Now we may assume φ achieves its infimum at infinity. Then there exists a sequence $\{p_k\}$ of points in Σ such that as $k \rightarrow \infty$ we have $p_k \rightarrow \infty$ and

$$(4.5) \quad \frac{\kappa_1}{H}(p_k) \rightarrow \epsilon_0 := \varphi^{-1}(\xi) < 0.$$

We note that if Σ is 2-convex and asymptotic to a cone \mathcal{C} , then the sum of the smallest two principal curvatures of the asymptotic cone \mathcal{C} is nonnegative. On the other hand, for any cone, there is a principal curvature which is 0. Thus the cone \mathcal{C} must be a convex cone, and 0 is the smallest principal curvature of the asymptotic cone \mathcal{C} . Then by Lemma 4.2, we have $\kappa_1 = O(r^{-3})$ and $H = O(r^{-1})$, as $r \rightarrow \infty$. Moreover, as the asymptotic cone \mathcal{C} is mean convex so that at least one principal curvature is positive, by (4.4) in Lemma 4.2, the mean curvature of Σ is exactly linear decay, i.e., $H \approx r^{-1}$, as $r \rightarrow \infty$. Thus $\kappa_1/H(p_k) \rightarrow 0$ as $p_k \rightarrow \infty$, which contradicts (4.5).

It follows from **Case 1** and **Case 2** that Σ^- is an empty set. Therefore Σ must be convex. This completes the proof of Theorem 1.2. \square

By Remark 2.3, Remark 4.1, and the same argument in the proof of Theorem 1.2, we also obtain the following result for 2-convex asymptotically conical self-shrinkers.

Theorem 4.1. *Let $\Sigma^n \subset \mathbb{R}^{n+1}$, $n \geq 3$, be a complete immersed two-sided 2-convex self-shrinker asymptotic to mean convex cones. Then Σ^n is convex.*
