

# CultureBERT: Fine-Tuning Transformer-Based Language Models for Corporate Culture

Sebastian Koch\*

Stefan Pasch<sup>§</sup>

This Version: January 4, 2023<sup>†</sup>

## Abstract

This paper introduces supervised machine learning to the literature measuring corporate culture from text documents. We compile a unique data set of employee reviews that were labeled by human evaluators with respect to the information the reviews reveal about the firms' corporate culture. Using this data set, we fine-tune state-of-the-art transformer-based language models to perform the same classification task. In out-of-sample predictions, our language models classify 16 to 28 percent points more of employee reviews in line with human evaluators than traditional approaches of text classification. We make our models publicly available.

**Keywords:** corporate culture, organizational culture, natural language processing, transformer-based language models

# 1. Introduction

In recent years, researchers have increasingly measured corporate culture by applying computational linguistic techniques to large textual data sets, consisting of, for example, employee reviews (Grennan 2019, Corritore et al. 2020), annual reports (Fiordelisi and Ricci 2014), or earnings calls (Li et al. 2021). However, studies following this approach often exhibit two major weaknesses. First, most computational linguistic techniques do not take the semantic context of words into account. Second, most studies do not evaluate in how far their measures of corporate culture align with the assessment of human evaluators. In addition to these weaknesses, most studies do not publish their language models in a way that allows other researchers to easily benchmark them against other computational linguistic techniques. In this paper, we address all of these issues.

We construct a unique data set of employee reviews that were labeled by human evaluators with respect to the information the reviews reveal about the firm’s corporate culture. Using this labeled data set, we apply *supervised* machine learning, which to our knowledge has not yet been used to measure corporate culture from text documents. More specifically, we fine-tune state-of-the-art transformer-based language models and show that they further improve on the computational linguistic techniques applied in the literature to measure corporate culture so far. Transformer-based language models allow to capture complex aspects of textual information by taking the surrounding context into consideration. Their development has accelerated since the publication of *Bidirectional Encoder Representations from Transformers* (BERT; Devlin et al. 2018). BERT set new high scores in various natural language processing tasks, such as question-answering, fact-checking, and text classification (González-Carvajal and Garrido-Merchán 2020). While transformer-based language models have already been used in financial sentiment analysis (Araci 2019), patent classification (Lee and Hsiang 2020), biomedical text mining (Lee et al. 2020), or hospital readmission prediction (Huang et al. 2019), we are not aware of any application with respect to corporate culture.

Our procedure of fine-tuning transformer-based language models for corporate culture classification is as follows:

- We randomly draw a sample of 2,000 employee reviews from a leading career community website.
- We create a labeled data set by determining for each of the 2,000 employee reviews whether it contains information either in accordance or in opposition with the four culture dimensions of the Competing Values Framework (CVF; Quinn and Rohrbaugh

1983). Moreover, we assign each review to the CVF’s culture dimension that best matches the employee’s description.

- We use a subset of this labeled data set to train transformer-based language models to classify employee reviews in the same way.

We find that our fine-tuned language models for corporate culture are more accurate than traditional computational linguistic techniques in classifying employee reviews with respect to corporate culture in the same way as human evaluators. Specifically, our models achieve a 16 to 28 percentage point higher accuracy than the dictionary method — a particularly popular approach of measuring corporate culture by comparing the text document of interest with a set of words that is thought to be characteristic of the cultural dimension under study. Moreover, our transformer-based language models outperform other machine learning-based text classifiers by five to fifteen percentage points in accuracy. Our findings illustrate the usefulness of transformer-based language models not only for measuring corporate culture but also for studying organizational phenomena more generally.

Different from most other studies, we make our language models publicly available.<sup>1</sup> This allows other researchers to measure corporate culture from employee reviews or similar text documents without having to build their own language model for corporate culture classification. Moreover, it allows other researchers to benchmark our transformer-based language models against alternative computational linguistic techniques.

The remainder of the paper is organized as follows. In the following section, we explain how our paper relates to the literature. In section 3, we present our data. In section 4, we explain how we trained our language models for corporate culture classification. In section 5, we compare our models’ performance in classifying employee reviews with the performance of traditional computational linguistic techniques. In the last section, we provide a discussion of our findings.

## 2. Related Literature

In this section, we introduce the Competing Values Framework, which is the conceptual framework we use for measuring corporate culture. Next, we show how our approach of measuring corporate culture differs from other computational linguistic techniques applied in the literature so far.

---

<sup>1</sup> Our language models are uploaded on the Huggingface model hub. See <https://huggingface.co/CultureBERT>.

## 2.1 Competing Values Framework

We follow O'Reilly and Chatman (1996, p. 160) and define corporate culture as “a system of shared values (that define what is important) and norms that define appropriate attitudes and behaviors for organizational members (how to feel and behave).” To create a labeled data set of employee reviews, we need a framework that lets us decide how to group the values, norms, and behaviors expressed in employee reviews into specific types of corporate culture. We make use of the competing values framework (CVF; Quinn and Rohrbaugh 1983), which is one of the frameworks most widely used for measuring corporate culture in both scientific research and practice (Hartnell et al. 2011, Chatman and O'Reilly 2016).

**FIGURE 1**  
**Competing Values Framework**

Adopted from Figure 3.1 in Cameron and Quinn (2011).

According to the CVF, organizations can be described along two basic value dimensions: their *focus* and their preference for *structure*. With respect to the focus dimension, organizations can be placed on a continuum between an internal focus, with an emphasis on internal capabilities and integration, and an external focus, with an emphasis on external opportunities and differentiation from competitors (Hartnell et al. 2019). With respect to the

structure dimension, organizations can be distinguished based on whether they prefer stability and control or flexibility and change. Plotting the focus and structure dimensions in a two-dimensional space yields four quadrants, of which each stands for one type of corporate culture: clan, hierarchy, adhocracy, and market (see Figure 1). For example, organizations exhibiting a clan culture tend to have an internal focus and a structure that emphasizes flexibility and change. Each of the four culture types is associated with certain assumptions, beliefs, values, behaviors, and effectiveness criteria (see Table 1). The clan culture, for example, puts special emphasis on values such as attachment, affiliation, or collaboration and is characterized by behaviors such as teamwork, participation, and employee involvement.

**TABLE 1**  
**CVF Culture Dimensions and Associated Attributes**

<b>Culture Type</b>	<b>Assumptions</b>	<b>Beliefs</b>	<b>Values</b>	<b>Artifacts (behaviors)</b>	<b>Effectiveness Criteria</b>
<b>Clan</b>	Human affiliation	People behave appropriately when they have trust in, loyalty to, and membership in the organization.	Attachment, affiliation, collaboration, trust, and support	Teamwork, participation, employee involvement, and open communication	Employee satisfaction and commitment
<b>Adhocracy</b>	Change	People behave appropriately when they understand the importance and impact of the task.	Growth, stimulation, variety, autonomy, and attention to detail	Risk-taking, creativity, and adaptability	Innovation
<b>Market</b>	Achievement	People behave appropriately when they have clear objectives and are rewarded based on their achievements.	Communication, competition, competence, and achievement	Gathering customer and competitor information, goal-setting, planning, task focus, competitiveness, and aggressiveness	Increased market share, profit, product quality, and productivity
<b>Hierarchy</b>	Stability	People behave appropriately when they have clear roles and procedures are formally defined by rules and regulations.	Communication, routinization, formalization, and consistency	Conformity and predictability	Efficiency, timeliness, and smooth functioning

Adopted from Table 13-1 in Quinn and Kimberly (1984) and Figure 2 in Hartnell et al. (2011).

It is important to note that the four culture types of the CVF are not mutually exclusive. A meta-analysis by Hartnell et al. (2011) revealed that they tend to be positively correlated, meaning that the same firm can exhibit several culture types at the same time. Therefore, some authors have suggested to refer to the culture types as culture dimensions (Hartnell et al. 2019). We follow this notation in order to make clear that a firm being characterized by more than one type of culture is rather the norm than the exception.

## 2.2 Measuring Corporate Culture by Computational Linguistic Techniques

A common approach researchers have used to measure corporate culture is to administer a survey among members of the corporation and ask them to characterize their organization along several dimensions. Starting from different theoretical backgrounds, different survey methods have been developed (see Chatman and O'Reilly (2016) for a review of the four most popular ones). For example, Cameron and Quinn (2011) proposed the Organizational Culture Assessment Instrument — a questionnaire to measure the four culture dimensions of the CVP. It requires the respondent to assess the corporate culture in six categories, including the corporation's dominant characteristics, its leadership, and its strategic emphases. The assessment is done by dividing 100 points across four alternatives — each alternative representing one of the CVP's culture dimensions. The final score for, say, the clan culture dimension is just the average number of points allocated to the alternatives representing the clan culture.

A drawback of measuring corporate culture with surveys is that assessing a large sample of corporations is both time- and resource-intensive. In this respect, the use of computational techniques to measure corporate culture from text documents provides an interesting alternative. With recent advancements in computing power and new textual data bases becoming available, the number of studies following this approach is growing rapidly (Chatman and Choi 2022). The text documents most commonly used to measure corporate culture include employee reviews (Grennan 2019, Pasch 2018, Corritore et al. 2020), annual reports (Fiordelisi and Ricci 2014, Pandey and Pandey 2019, Pasch and Ehnes 2020), and earnings calls (Li et al. 2021).

The earliest studies applying computational techniques to measure corporate culture have used the dictionary method. The idea of this method is to create a so-called dictionary or master text that is composed of the words that supposedly signal the cultural trait that is to be measured. The existence of a given cultural trait is then measured by the textual similarity between the corresponding dictionary and the text documents of interest, for example all employee reviews of a given firm. To construct the dictionary, different approaches have been applied. While Grennan (2019) uses the lexical database WordNet, Li et al. (2021) apply a word embedding model.

Another computational technique researchers have applied to measure corporate culture from text documents is probabilistic topic modeling. It is an *unsupervised* machine learning method that is used to analyze which themes are covered in a given text. Corritore et al. (2020), for example, apply *latent Dirichlet allocation* (LDA; Blei et al. 2003) — the topic model most

widely used in studies on corporate culture — to measure cultural heterogeneity both between and within employees from employee reviews. However, especially if corporate culture is not the main focus of the text documents to be analyzed, many of the themes a topic model uncovers may not be related to corporate culture at all. Therefore, topic modeling is not well suited for the use case we look at, which is to identify specific culture dimensions from employee reviews in which employees talk about more than just corporate culture. We will come back to this point in our discussion.

We contribute to the literature on the measurement of corporate culture by introducing *supervised* machine learning. It differs from unsupervised machine learning methods, such as topic modeling, in that a labeled data set is used. With supervised learning, an algorithm is trained to predict these labels. Our supervised learning approach consists of fine-tuning transformer-based language models for corporate culture classification. First introduced with BERT (Devlin et al. 2018), transformer-based-language models now represent the state-of-the-art in natural language processing. They allow to capture complex aspects of textual information by taking the surrounding context into consideration and have been found to outperform traditional machine learning approaches in most natural language processing tasks (González-Carvajal and Garrido-Merchán 2020).

### **3. Data**

We collected 2,000 online employee reviews by drawing a random sample of all the reviews that were published on a leading employee review website between 2008 and 2018 and that matched the following two criteria: (i) The review was written by an employee or former employee working in the U.S and (ii) the employer is available in the Compustat database. We limit our sample to reviews of Compustat-listed firms to make our results comparable to other studies in which corporate culture is commonly linked to financial figures.

Each review includes several free text sections in which the reviewer can choose to talk about what she likes and dislikes about the employer and what changes she would recommend. We combined the free texts of the different sections in random order to obtain a single text for each review. All other information provided by the review besides the free text was discarded. Next, we classified the reviews according to the employer’s corporate culture. To do so, both authors and a research assistant (henceforth “labelers”) independently went over all reviews. For each of the CVF’s four culture dimensions, they assigned each review to one of three classes, depending on whether the review

- contains information in line with the culture dimension under question (“positive review”),
- contains information in opposite of the culture dimension under question (“negative review”), or
- does not allow any inference about the culture dimension under question at all (“neutral review”).

In addition, the labelers assigned each review to exactly one of the four culture dimensions — the dimension that best fitted the overall tone of the review. This was done because although a firm can be characterized by several culture dimensions simultaneously, one of these dimensions usually dominates (Cameron and Quinn 2011). In completing their labeling task, the labelers tried to stick as close as possible to the description of the four culture dimensions provided by Cameron and Quinn (2011) and Hartnell et al. (2011).

For each of the five classifications that needed to be made per review (one for each of the four culture dimensions and one for the dominant culture), the final classification was selected to be the majority vote of the three labelers. In case the labelers all had a different opinion, one of their decisions was picked at random. Table 2 provides the absolute frequency of review classifications by type of labeler agreement. All labelers agreeing on the same classification is the most frequent outcome for all five labeling tasks. The comparatively lower frequency of full agreement when picking the dominant culture can be explained by the fact that in line with the findings of Hartnell et al. (2011), reviews often include information that equally points to more than one culture dimension.

**TABLE 2**  
**Number of Reviews by Type of Labeler Agreement**

Type of agreement	Clan	Adhocracy	Market	Hierarchy	Dominant culture
No agreement	61	17	56	34	176
Two labelers agree	850	458	760	632	890
Full agreement	1089	1525	1184	1334	934
Sum	2000	2000	2000	2000	2000

We split our data set of 2,000 review classifications into a training (N=1,400), validation (N=200), and test set (N=400). While we used the training set to fine-tune various transformer-based language models for corporate culture classification, we used the validation set to evaluate different hyperparameters and to determine which language model achieves the highest classification performance after having been fine-tuned for corporate culture

classification. We used the test set, in turn, to reliably evaluate how our language models for corporate culture perform in comparison to more traditional approaches.

## 4. Model Training and Benchmarks

In this section, we first explain how we fine-tuned transformer-based language models for corporate culture classification. Thereafter, we look at two alternative approaches for text classification of corporate culture: (i) the dictionary method, and (ii) a supervised machine-learning approach that relies on *Term Frequency-Inverse Document Frequency* (TF-IDF) matrices but does not incorporate recent advancements in the development of transformer-based models.

### 4.1 Transformer-Based Models

To build a language model for corporate culture, we start-off with the two most widely-used language models that are based on the transformer architecture (Vaswani et al. 2017) BERT (Devlin et al. 2018) and RoBERTa (Liu et al. 2019).<sup>2</sup> Both of these models have been trained on large unlabeled text corpora, including books and Wikipedia articles. As the name suggests, RoBERTa (*Robustly optimized BERT approach*) builds on BERT. However, it achieves higher performance in standard natural language processing tasks due to an improved training procedure and a much larger training data set (Liu et al. 2019). For both BERT and RoBERTa, a base version with around 100 million parameters and a large version with around 350 million parameters exists. With the help of a labeled data set, these general purpose language models can be fine-tuned for specific natural language processing tasks. This is exactly what we do in this paper. Using the training portion of our data set, consisting of 1,400 human-labeled employee reviews, we fine-tune the base and the large version of BERT and RoBERTa for the task of text classification in the domain of corporate culture. In the next step, we draw on the 200 labels of our validation set to evaluate different hyperparameters and to compare the resulting performance of the four models we look at. In line with Liu et al. (2019), we find that RoBERTa consistently outperforms BERT, both with respect to the base and the large version of the model. We therefore focus on RoBERTa in the following. Table 3 presents the hyperparameters of our final analysis.

---

<sup>2</sup> On the Huggingface model hub, as of November 2022, BERT and RoBERTa show the highest number of downloads among the English language models used for text classification. See <https://huggingface.co/models>.

**TABLE 3**  
**Hyperparameters**

Number of epochs	8
Weight decay	0.01
Learning rate	$1e^{-5}$
Dropout rate	0
Batch size	16
Maximum sequence length	200

## 4.2 TF-IDF-Based Text Classifiers

Since supervised machine learning methods have not yet been used to measure corporate culture, we benchmark our transformer-based models with other text classification methods that also use supervised learning but do not yet incorporate text embeddings as is the case with transformer-based models. Such methods usually quantify the input text as a bag-of-words representation and apply machine learning algorithms to classify the text based on occurrence and co-occurrences of these words (González-Carvajal and Garrido-Merchán 2020). More specifically, texts are quantified with TF-IDF matrices that measure the occurrence of words in a text relative to the inverse number of occurrences in the entire document corpus. We follow González-Carvajal and Garrido-Merchán (2020) in computing the TF-IDF matrices with the `TfidfVectorizer` from `sklearn`. After the text has been transformed into a matrix representation, we apply traditional machine learning algorithms to classify the given text inputs. In particular, we use logistic regression, random forest, and XGBoost.

## 4.3 Dictionary Method

Following Grennan (2019) and Pasch (2018), we generate a dictionary for each of the CVF’s culture dimensions using the words that describe the associated assumptions, beliefs, values, behaviors, and effectiveness criteria that are mentioned in Quinn and Kimberly (1984). In addition, we included the synonyms and hyponyms of these words, using the WordNet library.

To measure the similarity between employee reviews and dictionaries, we apply two different methods: word count, which is the standard in applications of the dictionary method, and BERT-based textual similarity. Applying the word count method, we simply compute for each employee review and each culture dimension the share of words that appear in the corresponding dictionary. Before doing so, we stemmed both the dictionary and the employee reviews (“create” and “creation” become “creat”) and removed common stop words from the reviews (for example, “a”, “and”, “the”). Moreover, we take into account negations by

subtracting the share of word stems of the dictionary that appear in a sentence with a negation word, such as “not” or “never”.

A shortcoming of measuring textual similarity with word-count is that a review can contain a strong signal of a certain culture without explicitly using words from the dictionary. For example, an expression such as “things are done differently every week” is not flagged as pointing towards an adhocracy culture because no word such as “change” or “innovate” is present. Therefore, we also measure similarity between reviews and dictionaries using BERT-based textual similarity. BERT transforms both the review and the dictionary into a complex vector representation and therefore allows to capture more subtle similarities between them that go beyond an exact match of words. To obtain our BERT-based similarity measure, we apply a tool from Mulyar<sup>3</sup>.

The question of interest is how the dictionary method compares to our transformer-based language models in reproducing the human-generated corporate culture classification of employee reviews. For this purpose, the continuous similarity scores derived from the dictionary method need to be transformed into the discrete three-class-classification (positive, negative, or neutral) or four-class-classification (clan, adhocracy, hierarchy, market) of our labeling. We set the thresholds such that the relative frequency of the three or four classes matches the distribution in our training data set. For example, 21% of the reviews were labeled as showing evidence in accordance with a clan culture. Hence, the 21% percent of the reviews exhibiting the highest similarity with the clan dictionary were assigned to be positive with respect to a clan culture. We set the thresholds in this way to make sure that the dictionary method makes use of the same information as our language models. Our language models potentially picked up the distribution of reviews across labeling categories in the process of training them on the training data set.

## 5. Results

### 5.1 Accuracy Scores

In Table 4, we report the accuracy of different methods for classifying the 400 employee reviews of our test data set with respect to the CVF’s four culture dimensions. More specifically, the table presents accuracy scores, that is, the fraction of the 400 employee reviews that were classified in line with human labelers. In the category *dominant culture*, we analyze which of the CVF’s four culture dimensions best fits the review. Hence, we would expect that

---

<sup>3</sup> <https://github.com/AndriyMulyar/semantic-text-similarity>

a random classifier achieves an accuracy of 0.25. With respect to the four individual culture dimensions, a review can be classified to be positive, negative, or neutral. Therefore, a random classifier should achieve an accuracy of 0.33. Table 4 also lists the performance of a classifier that always chooses the label that occurs most frequently (*majority class*). In the category *dominant culture*, this is the culture dimension *market* and for the four individual culture dimensions, the most frequent label is 0, that is, a neutral review.

When applying the dictionary method, we find that it outperforms a random classifier in all categories. However, with the exception of the clan category, it fails to outperform a classifier that always predicts the majority class. Interestingly, we observe higher accuracy scores when the dictionary method is used with word count than when it is used with BERT-based similarity. The reason may be negations. Remember that we consider negations when applying the dictionary method with word count by subtracting the share of words of the dictionary that appear in a sentence with a negation word. In contrast, as part of the dictionary method, BERT only delivers a measure of textual similarity between employee reviews and dictionaries and therefore should not be expected to take negations into account.

**TABLE 4**  
**Accuracy Scores of Different Methods of Text Classification**

Method of text classification		Dominant culture	Clan	Adhocracy	Market	Hierarchy
Random		0.25	0.33	0.33	0.33	0.33
Majority class		0.38	0.41	0.80	0.68	0.64
Dictionary method	+ word count	0.35	0.44	0.73	0.58	0.62
	+ BERT similarity	0.34	0.44	0.62	0.49	0.56
TF-IDF	+ logistic reg.	0.48	0.61	0.81	0.69	0.69
	+ random forest	0.46	0.58	0.81	0.69	0.74
	+ XGBoost	0.47	0.59	0.82	0.74	0.74
RoBERTa	base	0.51	0.62	0.84	0.74	0.75
	large	0.63	0.68	0.89	0.79	0.82

Table reports accuracy scores, that is, the fraction of the 400 employee reviews of the test data set that were classified in line with human labelers. In the category *dominant culture*, it is determined which of the CVF’s four culture dimensions best fits the review. In the categories *clan*, *adhocracy*, *market*, and *hierarchy*, it is determined whether the review contains information in accordance with, in contradiction to, or does not contain any information that allows inference about the existence of the culture dimension under consideration.

Turning to the TF-IDF-based classifiers, we find that they outperform both a simple majority classifier as well as the dictionary method in all categories. With respect to our transformer-based language models, in turn, we observe that both RoBERTa-base and

RoBERTa-large outperform all benchmarks in all categories. Moreover, RoBERTa-large consistently shows higher accuracy scores than the base version of RoBERTa. Overall, RoBERTa-large outperforms the dictionary method by 16 to 28 percentage points. It also outperforms TF-IDF-based classifiers by five to fifteen percentage points.

## **5.2 Why Does RoBERTa-large Outperform the Dictionary Method?**

As the dictionary method still represents the standard approach in studies measuring pre-specified dimensions of corporate culture from text documents, we take a closer look at the reasons behind the performance difference between the dictionary method and our language models that are based on RoBERTa-large. Why is RoBERTa-large generally more accurate than the dictionary method in measuring corporate culture from employee reviews in line with human evaluators? To provide some insights on this question, we look at all reviews that RoBERTa-large classified in the same way as human evaluators but that were misclassified by the dictionary method. We limit our attention to reviews with less than 50 words, however. While it is generally difficult to explain the predictions of RoBERTa-large since they do not follow from a simple rule-based approach, this is less of a problem in short reviews. This is because in short reviews, there is often just a single word or phrase that provides evidence in favor of one classification or another.

We found three major reasons for why many of the reviews that are misclassified by the dictionary method are still correctly classified by RoBERTa-large. Table 5 provides the relative frequency of these reasons for each of our four language models for the CVF's individual culture dimensions. With respect to the clan and hierarchy dimension, in the majority of reviews that are correctly classified by RoBERTa-large but misclassified by the dictionary method, there is an expression that provides evidence in accordance with or in opposition to the culture dimension under consideration but does not use any of the word stems included in the respective dictionary. Hence, although actually positive or negative, the review is nevertheless classified as neutral when applying the dictionary method. For example, while the statement "they are quick to throw you under the bus" contradicts a clan culture, none of the statement's word stems is part of the dictionary for the clan dimension.

The second reason for why some of the reviews that are misclassified by the dictionary method are correctly classified by RoBERTa-large is that the review may use words that are included in the dictionary but in a different context. In this case, the review is wrongly classified as positive or negative when the dictionary methods is applied. In contrast, since transformer-based language models take the surrounding context into account, the review is correctly

classified as neutral by RoBERTa-large. For example, the remark that the job offers “a competitive compensation” does not signal a competitive corporate culture although the word “competitive” is used. A closer inspection reveals that a significant number of misclassifications is caused by a limited set of word stems. Among these are the word stems “benefit” in the market dictionary and “time” in the hierarchy dictionary as they are regularly used in a context completely independent of corporate culture. Moreover, the word stems “advanc”, “develop”, “growth”, and “grow” of the adhocracy dictionary turn out to be problematic as reviewers usually use them not to refer to an adhocracy culture but to talk about possibilities of career advancement and personal development. To rule out that the low accuracy of the dictionary method was caused by this set of problematic word stems alone, we reapply the dictionary method after removing all of these word stems from the dictionaries. This, however, does not significantly improve the accuracy of the dictionary method because it also alters the threshold for the similarity between dictionary and employee review above or below which a review is classified as positive or negative, respectively. Hence, several reviews that so far were correctly classified as neutral now are misclassified as positive or negative due to other words included in the dictionary but used in the review in a different context. As selectively removing some word stems from our dictionary could be seen as arbitrary, we also reapply the dictionary method using the dictionaries that Fiordelisi and Ricci ((2014)) propose for measuring the CVF’s four culture dimensions. None of the problematic word stems mentioned above is included in their dictionaries. Nevertheless, the accuracy scores we obtain using their dictionaries are highly similar to those reported for the dictionary method with word count in Table 4. The only exception is the clan dimension, for which we obtain a ten percentage point *lower* accuracy score when using their dictionary as opposed to ours. This is most probably because their dictionary for the clan dimension includes some very generic word stems, such as “employ” or “partner” that also often are used in a different context than corporate culture.

The third reason for why RoBERTa-large exhibits a higher accuracy than the dictionary method is its superior ability in correctly interpreting the meaning of phrases that even in the absence of a negation have the opposite meaning of what the words by itself suggest. One example is the usage of the imperative. The statement “communicate more with your employees” signals a lack of communication and hence provides evidence in opposition to a clan culture although the word “communication” is used. As another example, RoBERTa-large understands that a firm that is “very slow in change” exhibits the opposite of an adhocracy culture although the word “change” appears.

Less than ten percent of the reviews could not be assigned to any of the three reasons mentioned above. Among these are reviews for which more than one classification seemed reasonable. Hence, although the dictionary method did not yield a classification in line with human labelers, we keep these reviews separate from the other cases in which the misclassification clearly resulted from an inability in interpreting the text correctly.

After having explored why RoBERTa-large often classifies reviews correctly even if they are misclassified by the dictionary method, we turn to the opposite case. Why does RoBERTa-large sometimes misclassify reviews that the dictionary method classifies correctly? Since it is much more difficult to explain for RoBERTa-large than for the dictionary method why a given review was misclassified, we cannot provide a similar list of reasons as we have provided for the dictionary method. However, a closer inspection of the reviews that were correctly classified by the dictionary method but misclassified by RoBERTa-large reveals that these reviews tend to be less clear with respect to the information on corporate culture they provide. This is supported by the agreement among the human labelers. When the human labelers classified the 400 reviews of the test data set with respect to each of the four individual culture dimensions, the most frequent classification was picked by 2.6 labelers, on average. When looking at the subset of cases in which the dictionary method was in line with the human labelers but RoBERTa-large was not, however, only 2.3 labelers picked the most frequent classification.

**TABLE 5**  
**Reasons Why Reviews Correctly Classified by RoBERTa-large Were Misclassified by Dictionary Method**

Culture dimension	No. of reviews	Reason why review was misclassified by dictionary method	Share of reviews	Example	Classification of example	
					RoBERTa-large	dictionary method
Clan	62	Wording without words from dictionary	81%	They are quick to throw you under the bus.	negative	neutral
		Words from dictionary in different context	8%	It is fun <b>helping</b> customers find the right product.	neutral	positive
		Did not capture opposite meaning	10%	<b>Communicate</b> more with your employees.	negative	positive
		Other	2%			
Adhocracy	54	Wording without words from dictionary	19%	No room for new technologies.	negative	neutral
		Words from dictionary in different context	69%	All the red tape <b>creates</b> excessive work.	neutral	positive
		Did not capture opposite meaning	4%	Very slow in <b>change</b> .	negative	positive
		Other	9%			
Market	65	Wording without words from dictionary	22%	You are nothing but a number.	positive	neutral
		Words from dictionary in different context	71%	Offers <b>competitive</b> compensation.	neutral	positive
		Did not capture opposite meaning	2%	Reward actual <b>achievement</b> , not face time.	negative	positive
		Other	6%			
Hierarchy	54	Wording without words from dictionary	52%	There is too much change.	negative	neutral
		Words from dictionary in different context	41%	Company <b>consists</b> of nothing but thieves.	neutral	positive
		Did not capture opposite meaning	6%	The firm is constantly adjusting its <b>structure</b> .	negative	positive
		Other	2%			

Table considers all reviews with less than 50 words that RoBERTa-large classified in the same way as human labelers but that were misclassified by the dictionary method. In the example sentences, the word stems that are part of the dictionary of the respective culture dimension are marked in bold.

## 6. Discussion

We fine-tune transformer-based language models for classifying employee reviews with respect to their alignment with the four major culture dimensions proposed in the CVF: clan, hierarchy, adhocracy, and market. We draw on the CVF because it is one of the frameworks most widely used for measuring corporate culture in both scientific research and practice (Hartnell et al. 2011, Chatman and O'Reilly 2016). Of course, other frameworks for measuring corporate culture exist. According to the Organizational Culture Profile (O'Reilly et al. 1991), for example, corporate culture can be measured along six independent attributes: adaptiveness, integrity, collaboration, results-orientation, customer-orientation, and detail-orientation (Chatman et al. 2014). In principal, our analysis could be repeated using this different set of culture dimensions. This would require constructing new dictionaries for applying the dictionary method and creating a new labeled data set of employee reviews for applying supervised machine learning. Due to their advantages in understanding the meaning of words and taking semantic context into account, we expect that transformer-based language models would similarly outperform other approaches of text classification even if a different set of culture dimensions was used.

In evaluating the performance of our transformer-based language model, we compare them to the dictionary method as well as other supervised machine learning approaches based on TF-IDF matrices. We do not apply topic modeling, however. The reason is that a topic model is not well suited for identifying specific culture dimensions from text documents that are not specifically related to corporate culture. Since the employee reviews we use are free texts, they contain information on various job-related issues, many of which are not related to corporate culture at all. Not surprisingly, therefore, applying a topic model to the employee reviews from which we draw our data set predominantly yields groupings of words that are unrelated to corporate culture. For example, one topic consists of words specific to the flight industry, such as “flight” or “airline”, while another consists of words related to working time, such as “hour” or “schedule”. This is in line with findings of Schmiedel et al. (2019), who apply topic modeling to a data set of around 400,000 employee reviews of Fortune 500 companies from Glassdoor. Of the 70 topics they identify in the reviews, most are unrelated to corporate culture and instead are composed of words, for example, referring to a specific company, industry, or job function, or to job characteristics that employees seem to care about, such as work-life balance or home office. Corritore et al. (2020) also apply a topic model to measure corporate culture from employee reviews and address this issue by limiting the sample to sentences that contain the word “culture” or a close synonym. However, with this approach, a sentence like “All that

matters is getting things done” would be overlooked even though judged from the CVF, it provides clear evidence of a market culture. Hence, although applying a topic model to employee reviews does not require to specify *ex ante* what cultural content they are assumed to cover, it is nevertheless associated with making subjective decisions, for example, what part of the text to consider or how to interpret, label, and filter the topics obtained (Schmiedel et al. 2019).

We are aware of the fact that the accuracy of the computational linguistic techniques we evaluate may depend on the labeled data set we propose. Nevertheless, we think that our analysis provides valuable insights on the question to what extent the measures of corporate culture obtained by different techniques align with the assessment of human evaluators. Due to a lack of labeled data, no study has looked at this question so far. We hope that in the future more and larger labeled data sets on corporate culture will become available such that researchers can easily evaluate if their measures of corporate culture reflect how corporate culture is perceived by humans.

A common drawback of language models that are based on machine learning is that it is difficult to explain the predictions they deliver. In this regard, the transformer-based language models we use are no exception. Building on recent advancements in natural language processing, the language models for corporate culture we propose are highly complex. The upside of this increased degree of complexity is that our language models are able to capture subtle aspects of textual information, for example by taking the surrounding context into account. The drawback is that the classification of a given piece of text is much less tractable than that delivered by a more rule-based approach, such as the dictionary method, where each classification follows from a transparent step-by-step process. In this paper, our focus is to show that transformer-based language models are more accurate in measuring corporate culture from texts as assessed by human evaluators than traditional approaches of text classification. We have provided some insights why transformer-based language models achieve a higher accuracy than the dictionary method. Future work should explore more thoroughly what are the advantages of transformer-based languages in measuring corporate culture and other organizational phenomena but should also look at their limitations. This requires providing an explanation for the models’ predictions, for example by looking at Shapley values .
