Abstract. The EU ESCAPE project is developing ESAP, ESFRI¹ Scientific Analysis Platform, as an API gateway that enables the seamless integration of independent services accessing distributed data and computing resources. In ESCAPE we are exploring the possibility of exploiting EGI's OpenStack cloud computing services through ESAP. In our contribution we briefly describe ESCAPE and ESAP, the use cases, the work done to automate a virtual machine creation in EGI's OpenStack cloud computing, drawbacks and possible solutions.

1. Introduction

In this work we consider two use cases: the SKA Data Challenges used to prepare the Astronomy and Astrophysics community to work with the data to be generated by the Square Kilometer Array (SKA), and the use of containerized Virtual Observatory services. In our contribution, we describe the technical steps performed: we established a collaboration with the CESSGA cloud site to get access to on the necessary development and test resources and we automated the creation of a Virtual Machine through the EGI FedCloud client. We automated the installation on a cloud virtual machine instance of the suitable software. We present a first standalone prototype and design the interface to provide ESAP's users with EGI resources access.

¹ESFRI Research Infrastructures are facilities, resources or services of a unique nature, identified by European research communities to conduct and to support top-level research activities in their domains. The ESFRI Projects are Research Infrastructures in their preparation phase which have been selected for the excellence of their scientific case and for their maturity, according to a sound expectation that the Project will enter the Implementation Phase in a fixed period of time.

2. The ESCAPE Project

ESCAPE, the European Science Cluster of Astronomy & Particle physics ESFRI research infrastructures, is an EU funded project running from 2019 through early 2023. The project aims to address the Open Science challenges shared by a range of ESFRI facilities (SKA, CTA, KM3Net, EST, ELT, HL-LHC, FAIR) and pan-European research infrastructures (CERN, ESO, JIVE) in astronomy and particle physics. Our interest is focused on two of the main actions of the project:

- connect ESFRI projects to EOSC ensuring integration of data and tools
- establish interoperability within EOSC as an integrated multi-messenger facility for fundamental science.

3. The ESAP platform

ESAP, the ESFRI Science Analysis Platform, is a flexible science platform for the analysis of open access data available through the EOSC environment. Due to its modular and extensible architecture and design it can be used as a science platform toolkit for building “science platforms” which can be optimized to particular applications. It is can be deployed at a variety of scales: as a “Centralized ESAP”, providing flexible and convenient access to a wide spectrum of ESCAPE services or as a “Project ESAP”, providing a way for individual infrastructures, projects, etc to quickly integrate diverse capabilities into a unified service offering. The current prototype allows EOSC researchers

- to identify and stage existing data collections for analysis;
- to collect selected data in a "shopping basket" with the same mechanism implemented in the online stores, like Amazon, where you can save in your shopping cart the products you are interested in;
- to select among software tools and packages developed by the ESFRIs or bring their own custom workflows to the platform;
- to exploit the underlying computing infrastructure to execute those workflows.

Researchers can select datasets from different archives. A set of workflows Available in the ESCAPE OSSR (Open-source Scientific Software and Service Repository) is provided, the researchers can select the workflow of interest and then choose to deploy it in a suitable infrastructure.

4. The use cases

The workflows provided in ESAP are relative to use cases of interest for the ESFRI and big research infrastructures users. In our work we considered the need to provide users both with containerized software and with an environment allowing to run more containers, possibly also sequentially in an interactive environment. We considered specifically two use cases:

- To provide access to containerized IVOA-enabled applications²
- To provide an environment to run the workflow to process HI data cubes produced by radio interferometers, in particular large data cubes produced by future instruments like the SKA³⁴.

5. The EGI computing infrastructure

EGI is a federation of computing and storage resource providers delivering open solutions for advanced computing and data analytics to support research and development. The EGI Core is the EGI Federated Cloud Platform (FedCloud), a federation and management platform that pool together various resources. It provides various compute services. The applicable to our use cases are **Cloud Compute** which provides virtual machine-based computing with associated storage, providing users with the ability to deploy and scale virtual machines on-demand, and **Container Compute**, which supports running container-based applications with either Docker or Kubernetes on top of Cloud Compute. In this work, we exploited the cloud compute service and we plan to evaluate the container compute service in the future.

6. Automation of Virtual Machine creation in OpenStack EGI FedCloud feasibility

To create a VM in OpenStack EGI FedCloud, following the provided documentation⁵, we registered to the piloting purpose Virtual Organisation vo.access.egi.eu; we asked CESGA site support to be able to allocate needed resources (particularly a public IP address). Then, using the EGI FedCloud Python client⁶ we wrote a simple Django web application, easily integrated in ESAP, to automate the virtual machine creation process in the EGI FedCloud.

7. Lessons learned

We have identified some show stoppers in the virtual machine automation process:

- Public network.** Each site has a slightly different network configuration, and there is no a standard way to tell which one to use and how to setup the router for it. There is not a convention for network naming, so human intervention — guessing — is needed to establish which is a public network.
- Supported Virtual Organizations.** There is not a command in the FedCloud tool that lists the sites that support a certain virtual organisation.

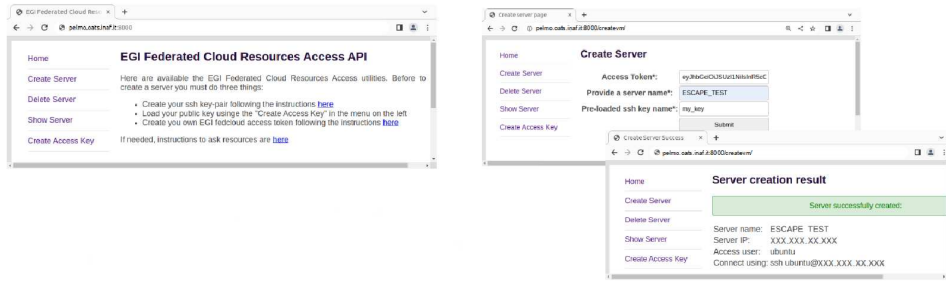

Figure 1. GUI EGI server creation

- **Flavors and images.** Again, human intervention is required to establish the resources associated to the flavors or the operating system in an image. A naming convention could be useful.

The authentication and authorization mechanism, as is, is not smooth because ESAP A&A is managed through InDiGo IAM and EGI A&A is managed through EGI Check-in, moreover the authentication in the virtual machine has to be done through ssh keys.

8. Thoughts on possible solutions

A workaround to the lack of information about supported Virtual Organizations and available VMs images and flavours could be the implementation of a service collecting and periodically updating the needed information through OpenStack/FedCloud client commands like

openstack image list to list available flavors

openstack image show <image> to display image details

openstack flavor list to list available flavors

openstack flavor show <flavor> to display flavor details

Authentication and authorization (A&A) at infrastructure level could be made smooth by exploiting the fact that InDiGo IAM and EGI Check-in are based on the same underlying technologies (OpenID Connect, with JSON Web Tokens for authentication and group membership for authorization) and making a mapping between entities. At low level, A&A could be made smooth exploiting a software like "motley cue" mapping OIDC identities to local identities.⁷

Acknowledgments. The project leading to this application has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 824064".

Thanks to CESGA for providing resources used in our tests.
