Abstract—This paper discusses the application of artificial intelligence (AI) technology in optical communication networks and 5G. It primarily introduces representative applications of AI technology and potential risks of AI technology failure caused by the openness of optical communication networks, and proposes some coping strategies, mainly including modeling AI systems through modularization and miniaturization, combining with traditional classical network modeling and planning methods, and improving the effectiveness and interpretability of AI technology. At the same time, it proposes response strategies based on network protection for the possible failure and attack of AI technology.

Index Terms—AI, 5G, Optical Networks

I. INTRODUCTION

Artificial intelligence (AI, artificial intelligence) technology is very early has been used in many fields, but for many years this technology has not gained high attention until AlphaGo defeated Chinese and Korean Go players After the hand, it began to become a research hotspot, and researchers tried to AI technology is applied in different fields, including optical communication network network. In the past two years, the United States Optical Communications Conference (OFC, optical fiber communication) and the European Conference of Optical Communications (ECOC, European conference of optical communication), at least 16 conference topics focused on AI or machine learning (ML, machine learning) technology. This paper combines AI technology and ML technology AI technologies are regarded as the same class of technologies, and at the same time, although AI technologies cover a wide range, The AI technology referred to in this article is mainly neural network technology.

AI technology has received widespread attention mainly due to the following two reasons. First, AI technology is relatively easy to get started and use. it comes in black Model the system in a box way, through a large number of samples Learning, let the black box connect neurons by itself, and distribute neurons Connect weights without requiring the user to understand why neurons behave the way they do connections and are assigned current weights. Users only need to provide enough learning samples, increase the number of neurons and the number of hidden layers, It can improve the prediction accuracy of AI technology. Second, AI technology is After the AlphaGo incident, it has almost been deified, and almost everyone knows that "people "artificial intelligence", and in the academic circle, the paper labeled AI Papers also

seem to be easier to publish, so this also leads to a current phenomenon Like, that is, for almost all problems, regardless of whether it is suitable or not, the use of AI technology for modeling and solving.

AI technology is very successful in solving some problems, as before Go and some image-to-speech recognition scenarios mentioned above, but cannot Due to the successful solution of a certain field or certain problems, AI is regarded as a "universal method". This paper aims at the current AI technology in optical communication Discuss the application of AI technology in the network, including the application of AI technology in optical communication network applicability in the network, and raises the potential risk of using AI technology Some coping strategies.

II. AI APPLICATIONS IN OPTICAL NETWORKS

AI technology has been widely used in the literature of optical communication networks [1]–[7]. A great deal of research can be found in this area. This paper introduces several representative applications of AI technology in optical communication networks. 1) On receiving At the end, using the digital signal processing method combined with AI technology, it can effectively improve the detection sensitivity of optical signals and improve the optical fiber transmission system performance and improve the spectrum utilization efficiency of the network [7], [8]. 2) In the optical network, there are a large number of end-to-end optical channels, and these optical channels are respectively related parameters (including transmission rate, modulation format, number of optical fiber links, number of optical amplifiers and gain, etc.) and their receiving the signal transmission quality (QoT, quality of transmission) detected by the end is used as input and output, and through a lot of learning, it can be realized Prediction of QoT for different end-to-end optical channels in optical networks; where QoT often expressed as the signal-to-noise ratio of the optical channel (OSNR, optical signal to noise ratio), its accurate prediction can reduce the optical channel OSNR margin configuration, thereby improving the spectrum utilization efficiency of the network [9], [10]. 3) pass Continuously learn the fault events in the optical network, and use the fault and fault cause Because it is used as input and output, it can accurately analyze and diagnose the cause of the fault early warning of future failures [3]. 4) Combined with the need for network

security, AI technology can also be used for early warning and identification of network attacks on the optical layer [11].

III. AI APPLICATIONS IN 5G COMMUNICATION

AI and ML are being utilized in 5G and mmWave communication [12]–[18] to enhance performance, reduce costs, and boost efficiency. Applications of AI in this field include network optimization, predictive maintenance, self-organizing networks, traffic prediction, security, resource allocation, network slicing, edge computing, interference management, and spectrum management. These technologies are still in the early stages of development but have the potential to significantly improve the performance, efficiency, and cost-effectiveness of these networks. As AI technologies continue to evolve and become more widely adopted, they will likely play an increasingly important role in the development and deployment of 5G and mmWave communication systems. However, it is also crucial to consider potential risks and challenges such as ensuring privacy, security, and ethical considerations.

AI techniques apply the same “black box” approach to different application scenarios leading to method innovation and analysis of the underlying mechanism slack. A very typical example is as follows. Thanks to AI technologies such as deep learning can effectively recognize some image patterns, there are studies that the researchers applied this technology to the identification of lesions in different parts of the human body [19], [20]. Based on the same method and process, different human parts are continuously used bit pictures, which can form a large number of so-called “research results” and thesis. Obviously, from the perspective of cultivating students and scientific research, students The development of research skills and professionalism acquired practically in the project are very few, and the actual work is only to collect relevant image data and Write a small amount of Python code, and finally hand over the training task to the graph Processor (GPU, graphics processing unit) to complete, no Carry out in-depth thinking on the method and mechanism of specific research questions It is obviously not conducive to innovation and effective innovation, and it is impossible to grasp (in fact, it is currently impossible to grasp) what is going on in the black box.
