

THE STABILITY OF SPLIT-PRECONDITIONED FGMRES IN FOUR PRECISIONS*

ERIN CARSON[†] AND IEVA DAUŽICKAITĖ[†]

Abstract. We consider the split-preconditioned FGMRES method in a mixed precision framework, in which four potentially different precisions can be used for computations with the coefficient matrix, application of the left preconditioner, and application of the right preconditioner, and the working precision. Our analysis is applicable to general preconditioners. We obtain bounds on the backward and forward errors in split-preconditioned FGMRES. Our analysis further provides insight into how the various precisions should be chosen; a suitable selection guarantees a backward error on the order of the working precision.

Key words. mixed precision, FGMRES, iterative methods, roundoff error, split-preconditioned

1. Introduction. We consider the problem of solving a linear system of equations

$$Ax = b, \quad (1.1)$$

where $A \in \mathbb{R}^{n \times n}$ is nonsymmetric and $x, b \in \mathbb{R}^n$. When A is large and sparse, the iterative generalised minimal residual method (GMRES) or its flexible variant (FGMRES) are often used for solving (1.1); see, for example, [15]. In these and other Krylov subspace methods, preconditioning is an essential ingredient. Given a preconditioner $P = M_L M_R$, the problem (1.1) is transformed to

$$M_L^{-1} A M_R^{-1} \tilde{x} = M_L^{-1} b, \quad (1.2)$$

where $M_R^{-1} \tilde{x} = x$.

Note that a particular strength of FGMRES is that it allows the right preconditioner to change throughout the iterations. Although for simplicity, we consider the case here where the preconditioners are static, our results can be easily extended to allow dynamic preconditioning.

The emergence of mixed precision hardware has motivated work in developing mixed precision algorithms for matrix computations; see, e.g., the recent surveys [1, 9]. Modern GPUs offer double, single, half, and even quarter precision, along with specialized tensor core instructions; see, e.g., [13]. The use of lower precision can offer significant performance improvements, although this comes at a numerical cost. With fewer bits, we have a greater unit roundoff and a smaller range of representable numbers. The goal is thus to selectively use low precision in algorithms such that performance is improved without adversely affecting the desired numerical properties.

Mixed precision variants of GMRES and FGMRES with different preconditioners have been proposed and analyzed in multiple papers. Arioli and Duff [4] analyzed a two-precision variant of FGMRES in which the right-preconditioner is constructed using an LU decomposition computed in single precision and applied in either single or double precision, and other computations are performed in double precision. They proved that in this setting, a backward error on the order of double precision is attainable. The authors of [12] develop a mixed

precision variant of left-preconditioned GMRES in a mix of single and double precisions, requiring only a few operations to be performed in double precision. Their numerical experiments show that they can obtain a backward error to the level of double precision. Vieublé [16] proved the backward stability of left-preconditioned GMRES in four precisions, following the earlier works [6] and [3] which analyzed left-preconditioned GMRES in two and three precisions, respectively. In general, different precisions can be used for computing the preconditioner, matrix-vector products with A , matrix-vector products or solves with the general preconditioner(s), and the remaining computations. We refer the readers to the recent surveys [1, 9] for other examples.

The stability of split-preconditioned GMRES and FGMRES has not been analysed in either uniform or mixed precision even though the structure of some problems makes it desirable to construct and apply a split-preconditioner rather than left or right ones. The work [5] showed that uniform precision FGMRES with a specific right-preconditioner is backward stable while this is not the case for GMRES and that FGMRES is more robust than GMRES. We thus focus on split-preconditioned FGMRES in this paper and develop a mixed precision framework allowing for four potentially different precisions for the following operations: computing matrix-vector products with A , applying the left-preconditioner M_L , applying the right-preconditioner M_R , and all other computations. FGMRES computes a series of approximate solutions x_k from Krylov subspaces to (1.1). The Arnoldi method is employed to generate the basis for the Krylov subspaces like in GMRES, but FGMRES stores the right-preconditioned basis as well. The particular algorithm is shown in Algorithm 1. Our analysis considers general preconditioners, only requiring an assumption on the error in applying its inverse to a vector, and is thus widely applicable.

The paper is outlined as follows. We bound the backward errors in Section 2 while also providing guidance for setting the four precisions such that backward error to the desired level is attainable. To make the results of the analysis more concrete, in Section 3 we bound the quantities involved for the example of LU preconditioners, and then present a set of numerical experiments on both synthetic problems and problems from SuiteSparse [7]. In Section 4 we make concluding remarks.

2. Finite precision analysis of FGMRES in four precisions. From the Rigal-Gaches Theorem (see [8, Theorem 7.1]), the normwise relative backward error is given by

$$\min\{\varepsilon : (A + \Delta A)x_k = b + \Delta b, \|\Delta A\| \leq \varepsilon\|A\|, \|\Delta b\| \leq \varepsilon\|b\|\} = \frac{\|r_k\|}{\|A\|\|x_k\| + \|b\|},$$

where $r_k = b - Ax_k$. We aim to bound this quantity when x_k is the approximate solution produced by Algorithm 1. To account for various ways in which the preconditioner can be computed and some constraints on A resulting in the need for different precisions, we assume that

- computations with A are performed in precision with unit roundoff u_A ;
- computations with M_L are performed in precision with unit roundoff u_L ;
- computations with M_R are performed in precision with unit roundoff u_R ;
- the precision for other computations (the working precision) has unit roundoff u .

Using the approach in [16], we assume that the application of M_L^{-1} and M_R^{-1} can be computed in a way such that

$$fl(M_L^{-1}w_j) = M_L^{-1}w_j + \Delta M_{L,j}w_j, \quad |\Delta M_{L,j}| \leq c(n)u_L E_{L,j}, \quad (2.1)$$

$$fl(M_R^{-1}w_j) = M_R^{-1}w_j + \Delta M_{R,j}w_j, \quad |\Delta M_{R,j}| \leq c(n)u_R E_{R,j}, \quad (2.2)$$

Algorithm 1 Split-preconditioned FGMRES for solving (1.1) in four precisions

Input: matrix $A \in \mathbb{R}^{n \times n}$, right hand side $b \in \mathbb{R}^n$, preconditioner $P = M_L M_R$, maximum number of iterations $maxit$, convergence tolerance τ , precisions u, u_A, u_L and u_R

Output: approximate solution x_k

```

where $fl(\cdot)$ denotes the quantity computed in floating point arithmetic, $E_{L,j}$ and $E_{R,j}$ have positive entries, $w_j \in \mathbb{R}^n$, and $c(n)$ is a constant that depends on n only. We define

$$\tilde{A} := M_L^{-1}A \quad \text{and} \quad \tilde{b} := M_L^{-1}b$$

and assume that matrix-vector products with \tilde{A} can be computed so that

$$fl(\tilde{A}z_j) = (M_{L,j}^{-1} + \Delta M_{L,j})(A + \Delta A_j)z_j.$$

Denoting

$$u_A \psi_{A,j} = \frac{\|M_L^{-1} \Delta A_j z_j\|}{\|\tilde{A}\| \|z_j\|} \quad \text{and} \quad u_L \psi_{L,j} = \frac{\|\Delta M_{L,j} A z_j\|}{\|\tilde{A}\| \|z_j\|},$$

where here and in the rest of the paper $\|\cdot\|$ denotes the 2-norm, and ignoring the second order terms, we can write

$$fl(\tilde{A}z_j) \approx \tilde{A}z_j + f_j,$$

where $\|f_j\| \leq (u_A \psi_{A,j} + u_L \psi_{L,j}) \|\tilde{A}\| \|z_j\|$.

In the following, a standard error analysis approach is used, e.g., [8], and we closely follow the analysis in [5] and [4]. The analysis is performed in the following stages:

1. Bounding the computed quantities in the modified Gram-Schmidt (MGS) algorithm that returns $C^{(k)} = \begin{bmatrix} \tilde{b} - \tilde{A}x_0 & \tilde{A}Z_k \end{bmatrix} = V_{k+1}R_k$, where $V_k^T V_k = I_k$, $R_k = \begin{bmatrix} \beta e_1 & H_k \end{bmatrix}$ and $e_1 = [1 \ 0 \ \dots \ 0]^T$.
2. Solving the least-squares problem

$$y_k = \arg \min_y \|\beta e_1 - H_k y\| \quad (2.3)$$

via QR employing Givens rotations and analysing its residual.

3. Computing $x_k = x_0 + Z_k y_k$.
4. Bounding $\|y_k\|$.

Throughout the paper computed quantities are denoted with bars, that is, $\bar{C}^{(k)}$ is the computed $C^{(k)}$, and $\kappa(A) = \|A\| \|A^\dagger\|$ is the 2-norm condition number of A . The second order terms in u_A , u_L , u_R , and u are ignored. We drop the subscripts j for $E_{L,j}$, $E_{R,j}$, $\Delta M_{L,j}$, $\Delta M_{R,j}$, ΔA_j , $\psi_{A,j}$ and $\psi_{L,j}$ and replace these quantities by their maxima over all j . $\kappa(B)$ is the 2-norm condition number of B . It is assumed that no overflow or underflow occurs. We present the main result here and refer the reader to Appendix A for the proof.

THEOREM 2.1. *Let \bar{x}_k be the approximate solution to (1.2) computed by Algorithm 1. Under the assumptions (2.1), (2.2),*

$$2.12(n+1)u < 0.01 \quad \text{and} \quad c_0(n)u\kappa(C^{(k)}) < 0.1 \quad \forall k, \quad (2.4)$$

$$|\bar{s}_k| < 1 - u \quad \forall k, \quad (2.5)$$

where $c_0(n) = 18.53n^{3/2}$ and \bar{s}_k are the sines computed for the Givens rotations, and

$$\rho := 1.3c_{13}(n, k)\|M_R\| (u\|\bar{Z}_k\| + u_R\|E_R\|) < 1, \quad (2.6)$$

the residual for the left-preconditioned system is bounded by

$$\|\tilde{b} - \tilde{A}\bar{x}_k\| \lesssim \frac{1.3c(n, k)}{1 - \rho} (\zeta_1 + \zeta_2), \quad (2.7)$$

where

$$\begin{aligned} \zeta_1 &:= (u + u_L\|E_L M_L\|) \|\tilde{b}\|, \quad \text{and} \\ \zeta_2 &:= (u + u_A\psi_A + u_L\psi_L) \|\tilde{A}\| (\|\bar{Z}_k\| \|M_R(\bar{x}_k - \bar{x}_0)\| + \|\bar{x}_0\|) \end{aligned} \quad (2.8)$$

and the normwise relative backward error for the left-preconditioned system is bounded by

$$\frac{\|\tilde{b} - \tilde{A}\bar{x}_k\|}{\|\tilde{b}\| + \|\tilde{A}\|\|\bar{x}_k\|} \lesssim \frac{1.3c(n, k)}{1 - \rho} \zeta, \quad (2.9)$$

where

$$\zeta := \frac{\zeta_1 + \zeta_2}{\|\tilde{b}\| + \|\tilde{A}\|\|\bar{x}_k\|}. \quad (2.10)$$

We expect (2.9) to be dominated by ζ_2 , mainly due to the term $\|\bar{Z}_k\| \|M_R(\bar{x}_k - \bar{x}_0)\|$. As observed in [5, 4] and in our experiments (Sections 3.1 and 3.2), $\|\bar{Z}_k\|$ remains small in early iterations, but can be large if many iterations are needed for convergence. We expect the quantity $\|M_R(\bar{x}_k - \bar{x}_0)\|$ to aid in partially mitigating the size of $\|\bar{Z}_k\|$, so that ζ_2 still gives good guarantees for the backward error. Note that if we were to obtain $\|\tilde{A}\|\|\bar{x}_k\|$ in

ζ_2 by using $\|M_R(\bar{x}_k - \bar{x}_0)\| \leq \|M_R\|(\|\bar{x}_k\| + \|\bar{x}_0\|)$, then we would introduce the term $\|M_R\|\|\bar{Z}_k\|$. Depending on the preconditioner, $\|M_R\|$ can be close to $\|A\|$ and for some problems $\|M_R\|\|\bar{Z}_k\|$ can grow rapidly, thus making (2.9) a large overestimate. We comment on how (2.7) compares with other bounds for FGMRES available in the literature in the following section. The quantities ψ_A, ψ_L and the role of different precisions are discussed in Section 2.2.

Bound (2.9) can be formulated with respect to the original system, that is, without the left preconditioner, using inequalities $\|b - A\bar{x}_k\| \leq \|M_L\|\|\tilde{b} - \tilde{A}\bar{x}_k\|$ and $\|b\| + \|A\|\|\bar{x}_k\| \geq (\|\tilde{b}\| + \|\tilde{A}\|\|\bar{x}_k\|)/\|M_L^{-1}\|$. We state the bound in the following corollary.

COROLLARY 2.2. *If the conditions in Theorem 2.1 are satisfied, then the normwise relative backward error for the system (1.1) is bounded by*

$$\frac{\|b - A\bar{x}_k\|}{\|b\| + \|A\|\|\bar{x}_k\|} \lesssim \frac{1.3c(n, k)}{1 - \rho} \zeta \kappa(M_L).$$

The condition number of the left preconditioner weakens the result, yet for some preconditioners $\kappa(M_L)$ can be expected to be small, for example when LU decomposition is used and $M_L = L$. We also note that a small backward error with respect to the preconditioned system and small $\kappa(\tilde{A})$ implies small backward error with respect to the original system; see Section 2.3 for an explanation.

2.1. Comparison with existing bounds. We wish to compare our result with bound (5.6) in [5] for FGMRES with a general right-preconditioner and bound (3.32) in [4] for FGMRES right-preconditioned with LU factorization computed in single precision. We set $M_L = I$, $u = u_A$, then $u_L = 0$ and $u_A\psi_A = u$. The bound (2.7) becomes

$$\|b - A\bar{x}_k\| \lesssim \frac{1.3c(n, k)u}{1 - \rho} (\|b\| + \|A\| (\|\bar{Z}_k\| \|M_R(\bar{x}_k - \bar{x}_0)\| + \|\bar{x}_0\|)).$$

We thus recover the bound (5.6) in [5], but ignoring the term $u^2\|\bar{x}_0\|$ and with a slightly different ρ . If we further set $\Gamma = \frac{\|M_R\|}{\|A\|}$ and use $\|M_R(\bar{x}_k - \bar{x}_0)\| \leq \|M_R\|(\|\bar{x}_k\| + \|\bar{x}_0\|)$, then our bound becomes

$$\|b - A\bar{x}_k\| \lesssim \frac{1.3c(n, k)u}{1 - \rho} (\|b\| + \|A\| (\|\bar{x}_k\| + \|\bar{x}_0\|) (1 + \Gamma\|A\|\|\bar{Z}_k\|)).$$

The main aspect in which this bound differs from (3.32) in [4] is that in [4] the term $\Gamma\|A\|\|\bar{Z}_k\|$ is controlled by a factor depending on u_R and the precision in which the LU decomposition used as M_R is computed. This comes from substitutions that rely on the specific M_R when bounding $\|\bar{y}_k\|$. Thus, when more information on M_R is available, reworking the bound for $\|\bar{y}_k\|$ may result in an improved bound.

2.2. Choosing the precisions. We provide guidance on how the precisions should be set when the target backward error is of order u . In our experiments we observe that the achievable backward error is determined by $u + u_A\psi_A + u_L\psi_L$ and we hence ignore the term $\|\bar{Z}_k\|\|M_R(\bar{x}_k - \bar{x}_0)\|$ in this section. We also note that because of the structure of the former term, we do not expect the backward error to be reduced by setting u_A or u_L so that $u_A\psi_A \ll u$ or $u_L\psi_L \ll u$. The aim is thus to have $u \approx u_A\psi_A \approx u_L\psi_L$ in (2.8).

- u_A . The precision for computations with A should be chosen so that $u_A \approx u/\psi_A$. Numerical experiments with left-preconditioned GMRES in [16] show that for large $\kappa(A)$ and $\kappa(M_L)$ the quantity ψ_A can be large and is driven by $\kappa(M_L)$. In such situations $u_A \ll u$ may be required. If, on the other hand, $\kappa(M_L)$ is small, then setting $u_A \approx u$ may be sufficient.

- u_L . Guidance for setting u_L comes from balancing $u \approx u_A \psi_A \approx u_L \psi_L$ and $u \approx u_L \|E_L M_L\|$. Based on the first expression, $u_L \approx u_A \psi_A / \psi_L$. Vieublé argues that $\psi_L \leq \psi_A$ is likely, and if $\kappa(A)$ and $\kappa(M_L)$ are large then we may observe $\psi_L \ll \psi_A$ [16]. In these cases we can set $u_L \geq u_A$ and $u_L \gg u_A$, respectively. The quantity $\|E_L M_L\|$ depends on M_L and the error in computing matrix-vector products with M_L^{-1} , which may be large for an ill conditioned M_L . In this case thus we may require $u_L \approx u$, which is consistent with the guidance for setting $u_A \ll u$.
- u_R . Our insight on u_R comes from the sufficient, but not necessary condition (2.6) (see Sections 3.1 and 3.2 for examples). It requires that $\|M_R\| \|E_R\| \ll u_R^{-1}$. E_R depends on the forward error of matrix-vector products with M_R . If $\kappa(M_R)$ is large, we may need a small u_R for the condition to be satisfied. When $\|M_R\|$ and $\kappa(M_R)$ are small, a large value for u_R may suffice. Note that these comments take into account the backward error only and not the FGMRES iteration count.

2.3. Forward error. A rule of thumb says that the forward error can be bounded by multiplying the backward error by the condition number of the coefficient matrix; see, for example, [8]. Using (2.9) thus gives the bound

$$\frac{\|x - \bar{x}_k\|}{\|x\|} \leq \frac{1.3c(n, k)}{1 - \rho} \zeta \kappa(\tilde{A}), \quad (2.11)$$

where x is the solution to (1.2) and \bar{x}_k is the output of FGMRES. Note that the bound depends on the condition number of the left-preconditioned matrix \tilde{A} . If $\kappa(\tilde{A})$ and ζ are small, then the forward error is small too, and thus $\bar{x}_k \approx x$. Then $b - A\bar{x}_k = A(x - \bar{x}_k)$ is small and implies a small backward error with respect to the original system as previously noted.

The forward error bound can also be formulated with respect to the split-preconditioned matrix $\hat{A} := M_L^{-1} A M_R^{-1}$ as follows

$$\frac{\|x - \bar{x}_k\|}{\|x\|} \leq \frac{1.3c(n, k)}{1 - \rho} \zeta \kappa(\hat{A}) \kappa(M_R). \quad (2.12)$$

The bounds (2.11) and (2.12) suggest that guaranteeing a small forward error requires controlling the backward error and constructing the preconditioners so that either $\kappa(\tilde{A})$ or both $\kappa(\hat{A})$ and $\kappa(M_R)$ are small. If A is ill conditioned, then achieving a small $\kappa(\hat{A})$ in (2.11) requires an M_L with a high condition number. Note that in this case, as discussed in the previous section, we may have to set $u_A \ll u$ and can get away with $u_L \gg u_A$. The bound (2.12) indicates that if we achieve a small $\kappa(\hat{A})$ at the price of $\kappa(M_R) \approx \kappa(A)$ then we cannot guarantee a smaller forward error than when no preconditioning is used because unpreconditioned FGMRES is equivalent to unpreconditioned GMRES in uniform precision with backward error bounded by $\frac{cnu}{1-cnu}$, where c is a constant [14].

3. Example: LU preconditioner. We supplement the theoretical analysis in the previous section with an example. Assume that an approximate LU decomposition of A is computed, for example in a low precision, and the computed factors \bar{L} and \bar{U} are used for preconditioning, i.e., $M_L = \bar{L}$ and $M_R = \bar{U}$. In Algorithm 1, products with A are computed in precision u_A and hence

$$\psi_{A,j} = \frac{\|M_L^{-1} \Delta A_j z_j\|}{u_A \|\tilde{A}\| \|z_j\|} \leq \tilde{c}_1(n) \frac{\|\bar{L}^{-1} \|A\| \|z_j\|}{\|\bar{L}^{-1} A\| \|z_j\|} = \tilde{c}_1(n) \frac{\|\bar{L}^{-1} \|A\|}{\|\bar{L}^{-1} A\|}, \quad (3.1)$$

where $\tilde{c}_i(n)$ is a constant that depend on n . We expect $\|\bar{L}^{-1} \|A\| / \|\bar{L}^{-1} A\|$ to be moderate for many systems and in this case setting $u_A = u$ may be sufficient.

Table 3.1: Unit roundoff u for IEEE floating point arithmetics.

Arithmetic	u
fp16 (half)	$2^{-11} \approx 4.88 \times 10^{-4}$
fp32 (single)	$2^{-24} \approx 5.96 \times 10^{-8}$
fp64 (double)	$2^{-53} \approx 1.11 \times 10^{-16}$
fp128 (quadruple)	$2^{-113} \approx 9.63 \times 10^{-35}$

We apply M_L by solving a triangular system $\bar{L}w_j = (A + \Delta A_j)z_j$ via substitution in precision u_L . From standard results we know that the computed \bar{w}_j satisfies

$$\begin{aligned} (\bar{L} + \Delta L_j)\bar{w}_j &= (A + \Delta A_j)z_j, \\ \text{where } |\Delta L_j| &\leq \tilde{c}_2(n)u_L|\bar{L}|. \end{aligned}$$

Thus

$$\Delta M_{L,j} = \bar{L}^{-1} - (\bar{L} + \Delta L_j)^{-1} \approx \bar{L}^{-1}\Delta L_j\bar{L}^{-1}.$$

We use this to bound $\psi_{L,j}$ as

$$\psi_{L,j} = \frac{\|\Delta M_{L,j}Az_j\|}{u_L\|\bar{A}\| \|z_j\|} \approx \frac{\|\bar{L}^{-1}\Delta L_j\bar{L}^{-1}Az_j\|}{u_L\|\bar{L}^{-1}A\| \|z_j\|} \leq \frac{\|\bar{L}^{-1}\Delta L_j\| \|\bar{L}^{-1}A\| \|z_j\|}{u_L\|\bar{L}^{-1}A\| \|z_j\|} \leq \tilde{c}_3(n)\kappa_2(\bar{L}). \quad (3.2)$$

The bound (3.2) is obtained using the bound on the forward error of solving a triangular system. In general such systems are solved to high accuracy and thus we expect (3.2) to be a large overestimate. Note that bounds (3.1) and (3.2) hold for every j .

3.1. Numerical example: synthetic systems. We perform numerical experiments in MATLAB R2021a* using a setup similar to an example from [4]. An $n \times n$ coefficient matrix $A = UDV$ is constructed by generating random orthogonal $n \times n$ matrices U and V , and setting D to be diagonal with elements $10^{-c(j-1)/(n-1)}$ for $j = 1, 2, \dots, n$. The condition number of A is 10^c and we vary its value. The right hand side b is a random vector with uniformly distributed entries. The preconditioner is computed as a low precision LU factorization. Namely, for $c \in \{1, 2, \dots, 5\}$ we use $[\bar{L}, \bar{U}] = lu(mp(A, 4))$, where $mp(\cdot, 4)$ calls the Advanpix Multiprecision Computing Toolbox [2] and simulates precision accurate to four decimal digits; note that this has a smaller unit roundoff than IEEE half precision (see Table 3.1 for the unit roundoff values). For $c \in \{6, 7, \dots, 10\}$ we compute LU factorization in single precision using the built-in MATLAB single precision data type. We set $M_L = \bar{L}$ and $M_R = \bar{U}$, and $E_L = u_L|\bar{L}^{-1}||\bar{L}||\bar{L}^{-1}|$ and $E_R = u_R|\bar{U}^{-1}||\bar{U}||\bar{U}^{-1}|$. The left-preconditioner can slightly reduce the condition number of the coefficient matrix whereas the split-preconditioner achieves a high reduction (Table 3.2).

We set the working precision u to double. Bounds for ψ_A in Table 3.2 indicate that there is no need for $u_A < u$, thus we choose $u_A = u$. The preconditioners are applied using all combinations of half, single, double, and quadruple precisions. Half precision is simulated via the *chop* function [10], and Advanpix is used for quadruple precision. We expect $\kappa(M_L)$ to be a large overestimate for ψ_L . $\kappa(M_R)$ suggests that the condition $\rho < 1$ in (2.6) should be satisfied with u_R set to any of the four precisions, except half for large c values. The solver tolerance τ (see Algorithm 1) is set to $4u$ and we use $x_0 = 0$. For the unpreconditioned

*The code is available at <https://github.com/dauzickaite/mpfgmres/>.

Table 3.2: Synthetic problems. Condition numbers of the unpreconditioned and preconditioned coefficient matrices and preconditioners, and bounds for ψ_A and ψ_L ($\kappa(M_L)$ is also the bound for ψ_L). The preconditioners are computed in precision accurate to four decimal digits for $c < 6$ and in single precision for $c \geq 6$.

system, FGMRES converges in 200 iterations when $c = 1$ and does not converge for other c values.

We show results for $c = 5$ for all precision combinations (Figure 3.1), and for all c values with u_L set to single and u_R set to double (Table 3.3), and u_L set to double and u_R set to single (Table 3.4). We report the relative backward error (BE) of the original problem, that is,

$$\frac{\|b - A\bar{x}_k\|}{\|b\| + \|A\|\|\bar{x}_k\|}$$

and compute the dominant part of the backward error bound ζ (as defined in (2.10)).

From Figure 3.1, we can see that the achievable backward error and subsequently the forward error depends on u_L . As expected from theory, u_R does not affect the achievable backward error, however u_R influences the iteration count. Setting u_L to half results in extra iterations when $c = 1$, $c = 2$ and $c = 6$ (not shown). Note that setting u_L to quadruple, and u_R to double or quadruple does not give any benefit. As mentioned, the backward error bound (2.9) is dominated by ζ_2 . From Tables 3.3 and 3.4, we can see that the quantity $\|\tilde{Z}_k\| \|M_R(\bar{x}_k - \bar{x}_0)\|$ can become large, but it stays of the order of $\|\bar{x}_k\|$ or close to it (not shown) and thus ζ gives a good estimate of the backward error. The increase in the forward error compared to the backward error is well estimated by $\kappa(\tilde{A})$, whereas $\kappa(\hat{A})\kappa(M_R)$ is an overestimate. From Figure 3.1, we see that the condition $\rho < 1$ is sufficient, but not necessary as it is not satisfied when $c = 5$ and u_R is set to half.

3.2. Numerical example: application problems. We perform experiments with some ill-conditioned problems from the SuiteSparse collection [7]; see Table 3.5. We generate the right hand side vector b in the same way as for the synthetic problems. The preconditioner is computed as in the previous section, but in single precision, and the matrix A is converted to a full matrix due to the lacking single precision sparse matrix-vector product functionality in MATLAB. Note that the split-preconditioner reduces the condition number to the theoretical minimum or close to it, except for the problem with the highest $\kappa(A)$. However $\kappa(\tilde{A})$ and $\kappa(M_R)$ are of the order of $\kappa(A)$ and thus we expect to see its effect on the forward error. We set u_A and u to double based on the ψ_A bound; u_L and u_R are set as in the previous section. Unpreconditioned FGMRES does not converge in n iterations for any of the problems.

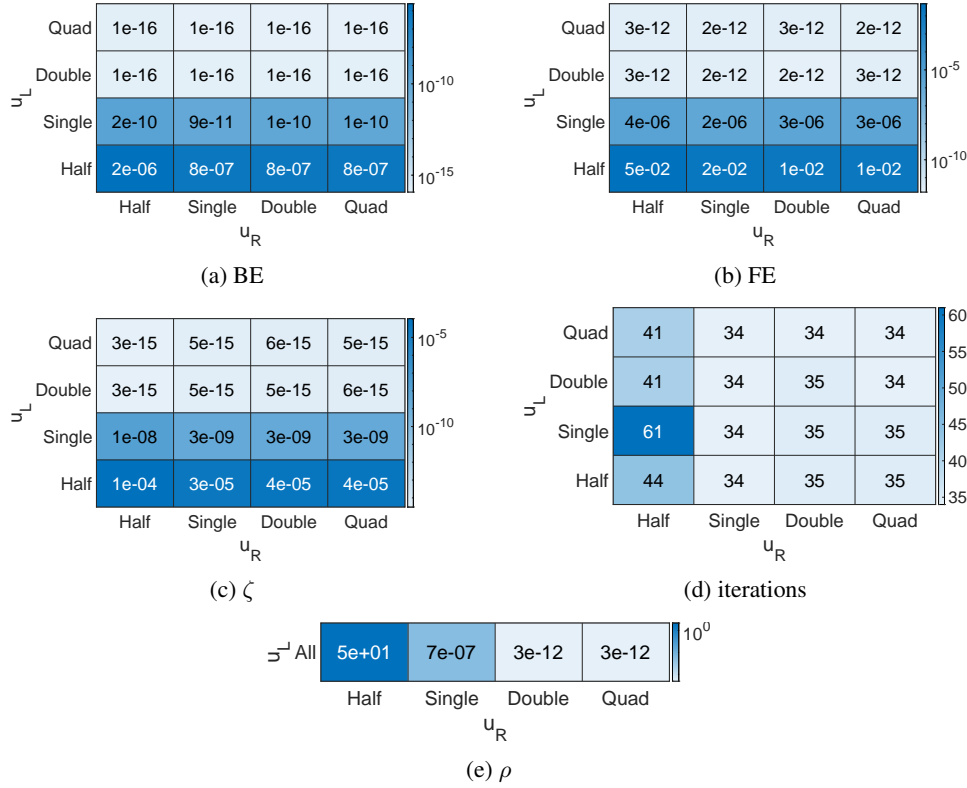

Fig. 3.1: Synthetic problem, $c = 5$. BE is the relative backward error and FE is the relative forward error, ζ is as defined in (2.10), and ρ is as defined in (2.6).

Table 3.3: Synthetic problems with u_L single and u_R double. IC denotes the iteration count, BE is the relative backward error and FE is the relative forward error. For $c = 10$, the solver is terminated at 200 iterations without satisfying the convergence criteria.

For all problems except *rajat14*, M_R is singular with respect to u_R set to half. This may be amended by using scaling strategies when computing the preconditioner, see, for example, [11]. We observe similar tendencies (Figures 3.2 and 3.3) as for the synthetic problems, however here we can achieve smaller backward error and for *fs_183_3* the backward error is $\mathcal{O}(u)$ even with u_L set to half. Note that for application problems setting u_L to a low precision results in iteration-wise slower convergence. The term $\|\bar{Z}_k\| \|M_R(\bar{x}_k - \bar{x}_0)\|$ grows

as for the synthetic problems, but is balanced by $\|\bar{x}_k\|$; see Tables 3.6 and 3.7.

In all of our application and synthetic examples, ψ_A/ψ_L does not become large enough to allow setting $u_L > u_A$ without it affecting the backward error. However for *fs_183_3* both ψ_A and ψ_L are small enough that we can set u_A and u_L to single and expect $\mathcal{O}(u)$ backward error. Numerical experiments confirm this even though the backward and forward errors become slightly larger compared to u_A set to double (not shown).

4. Concluding remarks. In light of great community focus on mixed precision computations, we analyzed a variant of split-preconditioned FGMRES that allows using different precisions for computing matrix-vector products with the coefficient matrix A (unit roundoff u_A), left-preconditioner M_L (unit roundoff u_L), right-preconditioner M_R (unit roundoff u_R), and other computations (unit roundoff u). A backward error of a required level can be achieved by controlling these precisions.

Our analysis and numerical experiments show that the precision for applying M_L must be chosen in relation to u , u_A , and the required backward and forward errors, because u_L heavily influences the achievable backward error. We can be more flexible when choosing u_R as it does not influence the backward error directly. Our analysis holds under a sufficient but not necessary assumption on u_R in relation to M_R . As long as M_R is not singular in precision u_R (note that scaling strategies may be used to ensure this), setting u_R to a low

precision is sufficient. Very low precisions u_L and u_R may delay the convergence iteration wise, yet setting $u_L \leq u$ or $u_R \leq u$ does not improve the convergence in general.

We observe that the forward error is determined by the backward error and the condition number of the left-preconditioned coefficient matrix. This motivates concentrating effort on constructing an appropriate left-preconditioner when aiming for a small forward error: the preconditioner should reduce the condition number sufficiently and needs to be applied in a

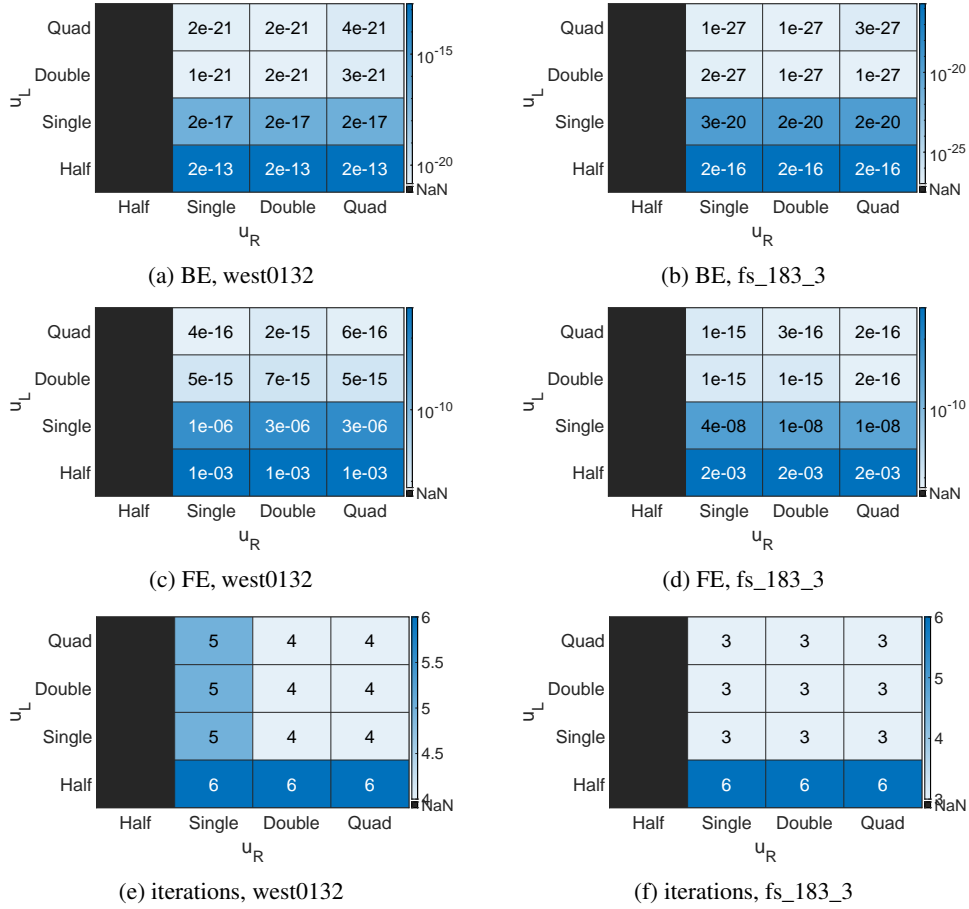

Fig. 3.3: SuiteSparse problems west0132 and fs_183_3. BE is the relative backward error and FE is the relative forward error.

suitably chosen precision.

Appendix A. Proof of Theorem 2.1. The analysis closely follows [5] and [4], and thus we provide the important results for each stage rather than the step-by-step analysis.

A.1. Left preconditioner. We start by accounting for the effect of M_L .

A.1.1. Stage 1: MGS. In this stage, we use precisions u , u_A and u_L . MGS is applied to

$$\bar{C}^{(k)} = \begin{bmatrix} fl(M_L^{-1}\bar{r}_0) & fl(\tilde{A}\tilde{Z}_k) \end{bmatrix}.$$

MGS returns an upper triangular \bar{R}_k and there exists an orthonormal \widehat{V}_{k+1} , that is $\widehat{V}_{k+1}^T \widehat{V}_{k+1} = I_{k+1}$, such that

$$\begin{bmatrix} \tilde{b} - \tilde{A}\tilde{x}_0 & \tilde{A}\tilde{Z}_k \end{bmatrix} + \begin{bmatrix} f_1 + f_2 + f_3 & F_k^{(1)} + F_k^{(2)} \end{bmatrix} = \widehat{V}_{k+1} \bar{R}, \quad (\text{A.1})$$

$$\|f_1\| \leq (u_A \psi_A + u_L \psi_L) \|\tilde{A}\| \|\tilde{x}_0\|, \quad (\text{A.1})$$

$$\|f_2\| \leq c_1(n) u_L \|E_L M_L\| \|\tilde{b}\| + u \left(\|\tilde{b}\| + (1 + u_A \psi_A + u_L \psi_L) \|\tilde{A}\| \|\tilde{x}_0\| \right), \quad (\text{A.2})$$

$$\|f_3\| \leq c_2(n) u \left(\|\tilde{b} - \tilde{A}\tilde{x}_0\| + (u_A \psi_A + u_L \psi_L) \|\tilde{A}\| \|\tilde{x}_0\| + c_1(n) u_L \|E_L M_L\| \|\tilde{b}\| \right), \quad (\text{A.3})$$

$$\|F_k^{(1)}\| \leq (u_A \psi_A + u_L \psi_L) \|\tilde{A}\| \|\tilde{Z}_k\|, \quad (\text{A.4})$$

$$\|F_k^{(2)}\| \leq c_3(n, k) u \left(\|\tilde{A}\tilde{Z}_k\| + (u_A \psi_A + u_L \psi_L) \|\tilde{A}\| \|\tilde{Z}_k\| \right). \quad (\text{A.5})$$

Here f_1 is the error in computing the matrix vector product $\tilde{A}\tilde{x}_0$ and f_2 accounts for computing $M_L^{-1}b$ and adding it to the computed $\tilde{A}\tilde{x}_0$. Error $F_k^{(1)}$ comes from computing $\tilde{A}\tilde{Z}_k$. f_3 and $F_k^{(2)}$ arise in the MGS process.

A.1.2. Stage 2: Least squares. The least squares problem is solved using precision u .

From the analysis of [5], under assumptions (2.4) and (2.5) the norm of the residual of the least-squares problem (2.3)

$$\alpha_k = \|\bar{\beta}e_1 + g^{[k]} - (\bar{H}_k + \Delta\bar{H}_k)\bar{y}_k\|$$

monotonically converges to zero for a finite $k \leq n$. We can express α_k in the following way:

$$\alpha_k = \|\tilde{b} - \tilde{A}\tilde{x}_0 + \delta\tilde{r}_0 - \tilde{A}(\tilde{Z}_k + \widehat{Z}_k)\bar{y}_k\|, \quad (\text{A.6})$$

where

$$\delta\tilde{r}_0 = f_1 + f_2 + f_3 + \widehat{V}_{k+1}g^{[k]}, \quad (\text{A.7})$$

$$\widehat{Z}_k = \tilde{A}^{-1} \left(F_k^{(1)} + F_k^{(2)} + \widehat{V}_{k+1}\Delta\bar{H}_k \right), \quad (\text{A.8})$$

$$\|g^{[k]}\| \leq c_5(k)u\|\tilde{b} - \tilde{A}\tilde{x}_0\| + c_5(k)u(u_A\psi_A + u_L\psi_L)\|\tilde{A}\|\|\tilde{x}_0\| + c_6(n, k)uu_L\|E_L M_L\|\|\tilde{b}\|, \quad (\text{A.9})$$

$$\|\Delta\bar{H}_k\| \leq c_4(k)u\|\tilde{A}\tilde{Z}_k\| + c_7(n, k)u(u_A\psi_A + u_L\psi_L)\|\tilde{A}\|\|\tilde{Z}_k\|. \quad (\text{A.10})$$

A.1.3. Stage 3: Computing \bar{x}_k . When certain conditions on the residual norm are satisfied, precision u is used to compute x_k as

$$\bar{x}_k = \bar{x}_0 + \bar{Z}_k\bar{y}_k + \delta x_k, \quad (\text{A.11})$$

$$\|\delta x_k\| \leq c_8(k)u\|\bar{Z}_k\|\|\bar{y}_k\| + u\|\bar{x}_0\|. \quad (\text{A.12})$$

Using this to eliminate $\bar{Z}_k\bar{y}_k$ in (A.6), then applying the reverse triangle inequality to bound $\|\tilde{b} - \tilde{A}\bar{x}_k\|$ and bounding $\|\delta\tilde{r}_0\|$, $\|\tilde{A}\delta x_k\|$ and $\|\tilde{A}\widehat{Z}_k\bar{y}_k\|$ gives

$$\begin{aligned} \|\tilde{b} - \tilde{A}\bar{x}_k\| &\leq c_{11}(n, k) \left((u + (1 + u)(u_A\psi_A + u_L\psi_L)) \|\tilde{A}\| (\|\tilde{x}_0\| + \|\bar{Z}_k\|\|\bar{y}_k\|) \right. \\ &\quad \left. + (u + u_L(1 + u)) \|E_L M_L\| \|\tilde{b}\| \right). \end{aligned} \quad (\text{A.13})$$

We eliminate $\|\bar{y}_k\|$ from the bound in the following section.

A.2. Right preconditioner. We now extend the analysis to account for the effect of applying M_R . Under assumption (2.2) \bar{Z}_k is computed such that

$$\bar{Z}_k = M_R^{-1} \bar{V}_k + \Delta M_R \bar{V}_k,$$

where $\|\Delta M_R\| \leq c_{12}(n)u_R\|E_R\|$. Then we can obtain

$$\begin{aligned} \|\bar{y}_k\| &\leq 1.3 (\|M_R(\bar{x}_k - \bar{x}_0)\| + \|M_R\|\|\delta x_k\| + \|M_R\|\|\Delta M_R \bar{V}_k\|\|\bar{y}_k\|) \\ &\leq 1.3c_{13}(n, k) (\|M_R(\bar{x}_k - \bar{x}_0)\| + u\|M_R\|\|\bar{Z}_k\|\|\bar{y}_k\| + u\|M_R\|\|\bar{x}_0\| + u_R\|M_R\|\|E_R\|\|\bar{y}_k\|). \end{aligned}$$

Under assumption (2.6)

$$\|\bar{y}_k\| \leq \frac{1.3c_{13}(n, k)}{1 - \rho} (\|M_R(\bar{x}_k - \bar{x}_0)\| + u\|M_R\|\|\bar{x}_0\|).$$

Using this in (A.13) and dropping the terms u^2 , uu_L and uu_A gives the required result.
